GAS JOURNAL

LIGHT ∴ HEAT ∴ POWER

BYE-PRODUCTS.

[Founded in 1849 as the "Journal of Gas Lighting."]

VOL. CLXX.

APRIL TO JUNE, 1925.

LONDON:

WALTER KING, LTD.,

11, BOLT COURT, FLEET STREET, E.C. 4.

1925.

INDEX

April to June, 1925.

[For Index of Register of Patents, Correspondence, Parliamentary Intelligence, and Legal Intelligence, see pp. vii. and viii.]

Abbirko Suction Service Cleanser, 1026
Abbott, Mr. W., on Technical Drawing, 240
Aberdeen Gas Undertaking, 131, 385, 670
Abergele, Price Reduction at, 193
Accidents—
  On Gas Works, 615
  Press Reports and, 669
Accounts, Field's Analysis of Gas, 650, 657
Accrington District Gas Board, 483, 677
Ackworth, Featherstone, &c., Gas Company, 1019
Air, Surveying Pipes by, 606
Alcohol, Power—
  Coke and, 360
  From Tuber and Root Crops, 258
Alder and Mackay, Ltd., 304
Aldershot Gas, Water, and District Lighting Company—
  Capital Issues Act, 360
  Meeting of Shareholders, 382
  Special Order Application, 69, 382
Allen's Commercial Organic Analysis, 528
Alliance and Dublin Consumers' Gas Company, 67, 751
America—
  Coke Oven Gas for Town Supplies in, 1022
  Gas Consumption per Head in, 521
  Gas Works Statistics, 367
  Industrial Gas Field in, 529
  Official Bulletins and Reports, 964
  Smoke Abatement Campaign in, 36
American Gas Association's Industrial Gas Field Survey, 529
American Refractories Institute, 314
Ammonia, Synthetic, 172, 447
Analysis, Commercial Organic, 528
Analysis of Gas Accounts, Field's, 650
Andover Lighting and Power Company, 263
Angus and Hill, Messrs., on Gas Fires and Carbon Monoxide, 106, 110
Anti-Eczema Soap for Gas Workers, 303
Arbroath, Price of Gas at, 675
Armstrong College of Science, 666, 667
Armstrong, Dr. E. F., on Chemistry, 181
Ashbourne Gas Undertaking, 968
Assessment Questions—
  Comments, 172
  Income Tax Allowances for Wear and Tear, 446, 471
  Metropolitan Water Board, 476
Atherstone Gas Light Company, 1020
Auckland (N.Z.) Gas Company, Ltd., 67, 250
Australia, Brown Coal in, 729
Australian Gas Light Company, 191, 261

B.Th.U. on Calorific Value and Gas Testing, 528
Bacon's, Prof. F., Address to the Wales and Monmouthshire Junior Gas Association, 57
Barford Electric Supply Company, 445
Barnard Castle Gas Company, 69
Barnet Gas and Water Company, 193, 322
Barrow Corporation Bill, 187, 677
Barrow Gas Undertaking, 1035
Barwell Public Lighting Question, 610
Becontree Housing Scheme, Gas for, 479
Bedford District Gas Company, 173
Belfast Gas Undertaking, 136, 477, 678
Bell's, Mr. J. Ferguson, Presidential Address to the Institution of Gas Engineers, 838, 863
Benzene, Centenary of, 966, 1016, 1021
Benzole—
  German Sales of, 1026
  Motor Spirit and, 128
  Research, 363, 654
Berthelot, M. C., on Coke Oven Gas in France, 110
Bexhill Corporation and the Gas Works, 130
Bexhill Gas and Water Company, 130
Bideford Gas and Coke Company, 1032
Bird, Mr. G. W., on Examples in Machine Design, 452
Birkenhead Gas Undertaking, 472
Birmingham Association of Mechanical Engineers —Mr. T. R. Speck on Furnace Design and Performance, 182
Birmingham Gas Meter Testing Department, 479
Birmingham Gas Undertaking—
  Annual Report, 968
  Motor Cars for Meter Inspectors, 387
  Pneumatic Handling of Oxide at Nechells Works, 527
  Price Increase, 968, 1032, 1034
  Staff Change, 173
  Supply to Small Houses, 189
Blackburn Gas Undertaking, 133, 136, 173, 482, 681
Blackburn, Soot Deposits in, 615
Blackpool Gas Undertaking, 193, 326, 752, 1035
Blairgowie Gas Company, 973
Blakeborough and Sons' Works Visited by the Yorkshire Junior Gas Association, 318
Blakey, Mr. R. F. W., on Thermal Balance Sheets, 124
Blyth Gas Company, 133
Boilers—
  Coke Fired—
    For Road Vehicles, 379
    Turbine Furnace for, 48
  Town Gas Fired, 58
Bollington Gas Undertaking, 322
Bolton Gas Undertaking, 193, 747
Bombay Gas Company, 322, 383, 680, 1019
Bone, Prof. W. A., on the Constitution of Coal, 240
Books Received—
  Accounts, Field's Analysis of Gas, 650, 657
  An Introduction to Technical Drawing (Abbott), 240
  Carburettor Handbook (Knott), 125, 362
  Central Stations Voltages and Charges, 1028
  Commercial Organic Analysis (Allen), 528
  Conversion of Coals into Oils (Lessing), 652
  Cost of Freight Transport by Railway (Rogerson), 532
  Electrician Tables of Electricity Undertakings, 465
  Examples in Machine Design (Bird), 452
  Exhibitions and the Arts of Display (Weaver), 725
  House Heating (Fishenden), 361, 463
  Low Temperature Distillation (North and Garbe), 125, 228
  Metal Workers' Practical Calculator (Matheson), 125, 361
  Preparing a Tender (Money), 460
  Progress of Applied Chemistry (Burton), 318
Booth, Mr. W. Newton, on Waste Heat Recovery, 49
Borrowing Powers, Special Orders and the One-half Proportion, 360, 446, 473
Boston (U.S.A.), Installing an Under-Water Gas Syphon at, 592
Bournemouth Gas and Water Company—
  Opposition to the Poole Harbour Bill, 66
  Pitwines Works, 117, 732
Bowden, Mr. J. H., on Heating Bath Water by Electricity, 675, 724
Boys, Prof. C. V., on Developments in Gas Calorimetry, 933, 1015
Bradford Gas Undertaking, 31, 109, 543
Bradford Municipal Technical College, 483
Bradford Shopping Week, 190
Brass Foundry, Gas Favoured in a, 966
Brechin Gas Undertaking, 257
Brentford Gas Company—
  Increase in Price, 263
  Official Tests, 322
  Opposition to Middlesex County Council Bill, 536
  Standard Price, 541
  Transfer to Gas Light and Coke Company, 61
Brentwood Gas Company, 477
Brereton, Mrs. Cloudesley, on Industry and Smoke Abatement, 731
Bridge of Allan Gas Undertaking, 304
Bridgeton (N.J.) Gas Light Company, 1023
Bridgwater Gas Light Company, 189
Brigg, Price of Gas at, 615
Brighouse Gas Undertaking, 134
Brighton and Hove Gas Company and the Shoreham Harbour Bill, 677
Bristol Gas Company, 615
British Association of Chemists, 181
British Commercial Gas Association—
  Fairy Gas Competition, 543
  Harrogate Conference—
    Clark, Dr. R. Veitch, on Light and Health, 672
    Editorial Comments, 648
    General Business, 671
    Robinson, Mr. F. H., on Gas as a Public Service, 672
  Literature, 448, 955
  North Wales and Cheshire District Conference—
    Editorial Comments, 358
    Evans, Mr. Owen, on National Economy in the Use of Coal, 375
    General Business, 374
    Hartley, Mr. H., on How the Gas Industry is Helping to Solve the Smoke Problem, 376
    Presidential Remarks of Sir John M. Frost, 374
    Rennett, Mr. D., on Smoke and the Public Health, 376
  Scottish Conference—
    General Business, 44
    Napier, Mr. J. W., on Gas Supply and Coal Economy, 45
    Whiteford, Mr. J. H. G., on Atmospheric Pollution Remedy, 46
  South Western District Conference—
    General Business, 530
    Noble, Mrs. R., on The Modern Labour Saving House, 531
    Vince, Mr. E. P., on Local Publicity, 530
British Empire Exhibition—
  Attendance Figures, 518
  Coke Exhibit, 728
  Editorial Comments, 299, 443, 722
  Gas Exhibit—
    Descriptions and Views of, 458, 524, 525, 589, 653, 727, 965
    Distinguished Visitors, 523, 727
    Editorial Comments, 443, 515
    Institution of Gas Engineers Visit, 841
    Plan of, 726
    Press Views, 523
    Reopening Ceremony, 449
    Subscription Lists, 136, 450
  Gas Supplies at, 453, 454, 729
  General Exhibits, 461
  Housing Section, Gas Installations in, 461, 523
  Illuminations, 227
  Main Equipped Kitchen at, 590
  Reopening Ceremony, 110, 443, 451
  Tarred Road Exhibit, 460, 465, 518, 729
  Weaver, Sir Lawrence, on the Art of Display, 725
  Woodall-Duckham Models, 460
British Engineers' Association, 522
British Gas Light Company's New Showrooms at Hull, 462
British Legion, 385
British Oxygen Company, Ltd., and Liquid Air Ltd., 67, 131
Bromsgrove Gas Company, 109
Brooklyn Union Gas Company, 966
Brush Industry, Gas in the, 314
Bryan Donkin Company's Works Visited by the Eastern Counties Association, 310
Budget, The, and Industry, 357
Budleigh Salterton Gas Company, 324
Building and Allied Trades Exhibition, 387
Burkheiser Purification Process, 41, 42
Burners, Aeration of, 879
Burnley Gas Undertaking—
  Annual Report, 747
  Extensions, 133, 751
  Pension Scheme, 973
  Price Increase, 546
  Staff Changes, 31, 842
  Sulphate Showroom Display, 193
  Sulzer Coke Cooling Plant, 1035
Burton, Mr. T. F., on Progress of Applied Chemistry, 318
Buxton Gas Undertaking, 224, 234, 483
Bye-Products—
  Exports of, 303, 584
  Prices, 72, 134, 191, 263, 322, 385, 482, 543, 614, 683, 752, 971, 1034
  Question in Parliament, 128
  Recovery, 965

Chemistry 62-805 No. 170

REMOTE STORAGE

Calendar Rolls, Gas for Heating, 367
Calorific Value—
  And Gas Testing, 526, 735
  Continuous Gas Sampling for, 1015
  Declarations of, 69, 477
  Low, and Unaccounted-for Percentages, 473, 534, 606
Calorimetry, Developments in, 933
Cambridge Gas Works, Visit of the London and Southern District Junior Gas Association to, 1022
Canadian Gas Association Convention, 938
Cannock, Hednesford, and District Gas Company, 585
Cape Town and District Gas Company, 543, 611
Carbon Black, Electrical Manufacture of, 964
Carbon Monoxide—
  Doctors, Coroners, and, 359
  Gas Fires and, 106, 110
  Motor Exhaust Gas Dangers, 362
Carbonization—
  Coal and, 175
  Complete Gasification Litigation, 476
  Low Temperature—
    Company (*see* Low Temperature Carbonization, Ltd.)
    Illingworth, Dr S. R., on, 741
    Lander, Dr. C. H., on, 242
    Low Grade Coal and, 473
    Megiun Vertical Retort for, 172
    North and Garbe, Messrs., on, 125, 228
    Warner Retort for, 185
Carburettor Handbook, 125, 362
Card Printing, Gas for, 725
Cardiff Gas Company, 323, 737
Carlisle Gas Undertaking—
  Annual Report, 973
  Main Extensions, 324
Carr, Mr. W. M., on the New Carbonizing Plant at Stretford, 915, 1029
Cast Iron Research, 1023
Centenary Celebrations—
  Benzene Discovery, 966, 1016, 1021
  Imperial Continental Gas Association, 477
  Keighley Gas Undertaking, 385
  South Metropolitan Gas Company, 305
Ceramic Society—Buxton Clay Convention (*see* Refractories)
Chagford and Devon Electric Light Company, 303, 584
Chandler, Mr. Dean, on Fuel in Industry, 243
Chapel Whaley and District Gas Company, 938
Chartered Institute of Secretaries, 528
Cheltenham Gas Light and Coke Company, 173
Chemical Manufacturers and the Gas Industry, 29, 841, 967, 1016
Chemical Topics from Current Literature, 252
Chemistry—
  Armstrong, Dr., on, 181
  Progress of Applied, 318
Chester United Gas Company, 385
Chesterfield Gas Undertaking, 323
Chicago, Air-Driven Wire Brushes for Gasholder Cleaning at, 241
Chorley Gas Undertaking, 483
Chrisman Down Run Process, 311
Cinemas, Gas for, 448, 955
City and Guilds of London Institute Examinations—
  Coal-Tar Distillation and Crude Intermediate Products, 481
  Coke and Bye-Products Manufacture, 481
  Gas Fitting, 480
  Gas Supply, 542
  Gas Works Practice, 542
Clark, Dr. R. Veitch, on Light and Health, 672
Clarkson, Mr. Thomas, on Coke as a Fuel for Road Vehicles, 379
Cleethorpes Gas Company, 519, 585
Clerk, Sir Dugald, on Town Gas for Motive Power, 939, 1029
Clitheroe Gas Undertaking, 324
Co-operation between the Gas Industry and the Trader, 729
Co-Partnership—
  Bill, 172
  Croydon Gas Company and, 613
  South Suburban Gas Company and, 750
  Todd, Mr. Duncan, on, 260

Coal—
  And Carbonization, 175
  Brown, in Australia, 729
  Constitution of, 240
  Conversion of, into Oils, 652
  Costs and Output, 107
  Economy, Gas Supply and, 15
  Exports, 303, 584
  Hydrogenation and Liquefaction of, 242
  Industry, Low Temperature Carbonization and the, 841
  National Economy in the Use of, 375
  Prices of Domestic, 650
  Publicists and, 171
  Pyrites in, 656
  Sampling, 470
  Spontaneous Combustion of, 447
  Trade Reports, 70, 134, 190, 263, 323, 385, 482, 544, 613, 682, 752, 971, 1033
Coal Mine Run by Workmen, 172, 517, 1017
Coal Mines—
  Gas Manufacture at the Pit Mouth, 31
  Labour Conditions, 31 226, 518, 582, 722, 841
  Nationalization Question, 722
Coal-Tar Distillation and Crude Intermediate Products, Examinations in, 481

Coke—
  And Power Alcohol, 360
  Bibliography of, 591
  Competition, 106, 170, 225, 302, 516, 841, 1018
  Cultivation of Domestic and Other Markets, 365
  Exports, 108, 303, 584
  In Gas Showrooms, 721
  Large Contract for, 446
  Price of, 60
  Quenching Water, Purification of, 177
  Sales by Analysis, 359
Coke and Bye-Products Manufacture, Examinations in, 481
Coke Oven Gas for Town Supplies, 110, 1022
Coke Oven Managers' Association—
  Parker, Dr. A., on Utilization of Waste Heat from Coke Ovens, 180
  Robinson, Mr. R. L., on the Possibilities in Bye-Product Recovery, 965
Coke Ovens, Utilization of Waste Heat from, 180
Colchester Gas Company, 69
Coleraine, Price of Gas at, 753
Colliery for Sale, 518
Colne (Lancs.) Gas Undertaking, 651
Colombo Gas and Water Company, 262, 651
Colonial Gas Association Capital Issue, 69
Commercial Gas Company—
  Death of Mr. H. E. Jones, 27, 32, 241
  London County Council and, 189
  Official Changes, 108
  Official Tests, 322
  Price Increase, 72, 172, 189
Companies, New Joint Stock—
  Geyser Manufacturing Company, 136
  Guest, Keen, and Piggotts, 483
  Premier Gas Mantles, Ltd., 973
  Riscavoid, 262
  Synthetic Ammonia and Nitrates, Ltd., 541
Company Promoters and the Gas and Electrical Industries, 30, 303, 445, 584, 1018
Compressor, Crankless Gas Engine and, 47
Congleton Gas Undertaking, 384
Consett Iron Company, Visit of the North of England Association to the Works of, 1027
Continental Union Gas Company, 528
Contracts Open, 69, 133, 190, 263, 323, 385, 485, 546, 613, 682, 752, 971, 1034
Conway Gas Undertaking, 260
Cooking, Electric, 304, 520, 586, 652
Corrosion, Prevention of, 256, 1026
Councillors and Contracts, 193
County of London Electric Supply Company, 586
Coventry Gas Undertaking, 133, 615, 683
Croydon Gas Company, 188, 613
Croydon Municipality and the South Metropolitan Gas Bill, 136
Current Topics, Dr. E. W. Smith on, 315
Czecho-Slovakia and the Smoke Problem, 735

D'Estape, M. L. Rolland, on the Tankless Gasholder at Arbel, Douai, France, 911
Dalton Gas Undertaking, 324
Darlington Gas Undertaking, 136
Dartford, Co-operative Display by Junior Engineers, 176
Dartmouth Gas, Coke, and Coal Company, 72
Darwen Gas Undertaking, 324
Davidson's, Dr. W. B., Claim Against the War Office in Connection with Toluole Extraction, 322, 381, 584
Deaths—
  Beetles, A. B., 109
  Best, R. H., 723
  Brockway, E. J., 519
  Browning, R. A., 651
  Bryant, W., 226
  Corbett, W., 109
  Dawson, A., 973
  Dempster, Robert, 584
  Dibdin, W. J., 842
  Ellison, H., 109
  Gardner, T. S. S., 31
  Garton, W., 723
  Jacob, A., 304
  Jones, H. E., 27, 32, 241
  M'Crae, Mrs., 109
  Mappin, Sir Wilson, 842
  Readshaw, J., 226
  Scott, Mrs. J. O., 304
  Spurrell, E. F., 723
  Thomas, J. M., 31
Dempster, Mr. Robert, Death of, 584
Dempster-Toogood Vertical Retorts, 367
Dental Surgeries and Clynics, Gas in, 228
Denton, Gas Exhibition at, 1035
Denver, Painting and Screening Gasholders at, 590
Derby Gas Light and Coke Company, 483, 956, 1022
Devizes Gas Undertaking, 131
Devon Gas Association, 190
Devonport (N.Z.) Gas Works, 251
Dewsbury Gas Undertaking, 387, 615
Dibdin, Mr. W. J., Death of, 842
Die Casting, Gas for, 524
Dip Pipes, Unsealed, and a Simple Alarm, 60
Directors, Gas Engineers as, 606
Donkin, Mr. C. Bryan, on Gas for Industry, 312, 378
Donkin (Bryan) Company's Works, 310
Drawing, An Introduction to Technical, 240
Drawing Office, The Modern, 54
Dru Drury, Mr. Charles, on Experiences with Gasholder Tanks in a Mining Area, 358, 368
Du-Ex Nipple, The, 323, 469
Dukinfield Gas Undertaking, 483
Dundee Gas Undertaking, 134
Dunfermline, Price of Gas in, 262

Dunn, Mr. W. T., on the Evolution of the Vertical Retort, 208, 367
Dursley Gas Light and Coke Company, Ltd., and Low Temperature Carbonization, Ltd., 67
Dysynni Gas Works Purchase Question, 1035

Earl Shilton Gas Light and Coke Company, 610
East Hull Gas Company, 108
Eastbourne Gas Company, 681, 1035
Eastern Counties Gas Managers' Association—
  Donkin, Mr. C. Bryan, on Gas for Industry, 312, 378
  Editorial Comments, 301
  Presidential Address of Mr. F. A. West, 237, 301, 473, 534, 606
  Visits—
    Bryan Donkin Company's Works, 310
    Newark Gas Works, 307
Edinburgh Gas Undertaking, 31
Education Scheme of the Institution of Gas Engineers—
  Editorial Comments, 223
  Gas Engineering, 478
  Gas Supply, 478
  Hole, Mr. Walter, on the, 235
  Report of the Advisory Committee, 877
Electrical Development Association, 111, 173, 174, 362, 651
Electrical Industry and the Sliding Scale, 66
Electrician Tables of Electricity Undertakings, 465
Electricity—
  All Electric Houses, 444, 650
  And Gas in Relation to Unemployment and Industrial Depression, 581, 595
  Central Station Voltages and Charges, 1028
  Colliery Super-Stations for Generating, 447
  Contractors, Registration of, 448
  Development—
    Government and, 229, 518, 581, 607, 647, 675, 720, 721, 724, 839, 1019
    In Residential Areas, 111, 173
  Fire Risks and Dangers of, 228, 305, 586, 652
  Gas Undertakings and the Supply of (*see* Gas)
  Inquiry into Domestic Supplies, 300, 361
  Joint Authorities and Compulsory Powers, 305
  Municipal Preference for, 111, 444, 650
  Output per Head of Population, 362
  Pit Head Generation of, 526
  Power Plant in Gas Works, 179
  Subsidizing (*see also* Development), 229
  Supply, Fuel Conservation and, 107, 171
  Tariffs, 227, 304, 447, 1028
  Undertakings, "Electrician" Tables of, 465
  Water Power for Generating, 228
Electricity Commissioners, 300, 1019
Ellesmere Port and Whitby Gas Undertaking, 477, 615
Engines, Gas—
  Michell's Crankless, 47
  Petrol for Starting, 668
  Safeguarding of, 241
  Town Gas for, 939
  Turbine, 365
European Gas Company, 966
Evans, Mr. Owen, on National Economy in the Use of Coal, 375
Evesham Gas Undertaking, 609
Evetts, Mr. George, on The Economics of Gas Production on the Thermal Basis, 943, 966
Ewart & Son, Ltd., 968
Examinations in—
  Coal-Tar Distillation and Crude Intermediate Products, 481
  Coke and Bye-Products Manufacture, 481
  Gas Engineering, 478, 651
  Gas Fitting, 480
  Gas Supply, 478, 542
  Gas Works Practice, 542
Examples in Machine Design (Bird), 452
Exeter Gas Company, 361, 973
Exhibitions—
  And the Arts of Display, 725
  British Empire (*see* British Empire)
  Buildings and Allied Trades, 387
  Co-Operative Display at Dartford, 176
  Electrical, 111
  Gas—

  Gibson, R. E., 858
  Haddock, W. S., 585
  Hatswell, F. T., 109

Personal (*continued*)—
Hodgson, R. B., 109
Horseley, G. F., 842
Jalland, B. G., 108
Johnson, S. B., 651
Jones, F. H., 226
Knight, H. S., 109
Langstreth, G., 31
M'Lusky, J. W., 109
Munro, A. B., 31
Nicholls, T. A., 585
Paterson, J., 585
Perkins, R. D., 109
Prince of Wales, 31
Pykett, F. A. C., 1026
Reeson, J. N., 1019
Ritson, T. N., 226
Scobie, J., 226
Scott, J. W., 109
Thorpe, H., 651
Walker, J. W., 519
Ward, H. J., 522
West, F. J., 304
Whitaker, J , 31, 109
Whiteley, A., 173
Wilson, R. L., 304
Phenol, Recovery of, from Effluents, 730
Photography by the Light of High Pressure Street Lamps, 526
Pipes—
Du-Ex Expansion Nipple for, 323, 469
Ford Trenching Machine for, 533
Liability for Damage to, Through Faulty Road Filling, 677
Methods of Dealing with Leakages in, 742
Of Insufficient Capacity, 650, 677, 722
Selecting and Testing Wrought Iron, 124
Surveying, by Air, 606
Pitch, Getting and Loading, 468
Pittsfield (Mass.), Gasholder Fire at, 532
Plant Design and Control, 619
Plymouth and Stonehouse Gas Company, 747
Plymouth Corporation and the Gas Company's Works, 747
Pneumatic Handling and Revivification of Oxide, 527
Pontypridd Gas Undertaking, 741
Poole Harbour Bill, 66
Poplar Electricity Undertaking, 585, 675, 724, 747, 1020
Poplar Wages Surcharge, 172
Porter, Dr. H. C., on—
Gas at the Pit's Mouth, 31
Low Temperature Coal Carbonization, 185
Portsea Island Gas Light Company, 324
Potato Chips, Gas for Cooking, 743
Premier Gas Mantles, Ltd., 973
Printing Exhibition, Gas at, 606, 736
Psychologist on Efficiency in Gas Works, 175
Public Utility Companies (Capital Issues) Act, 107, 360, 446, 473
Publicity—
English Expenditure on, 122
Local, 530
Purchase and Amalgamation Questions—
Bexhill, 130
Brentford, 61
Pysynni, 1035
Haverton, 129
Plymouth, 747
Purification—
Of Coke Quenching Water, 177
Processes, 29, 41
Pyrometer, Leeds and Northrup Potentiometer, 1023

Queenstown Gas Company, 70
Quigley Refractory Gun, 938

Radiation, Ltd., 68, 184
Railroads, Gas to Melt Snow and Ice on, 668
Railway Transport, The Cost of Freight by, 532
Railway Wagons, Economy of 20-Ton, 31
Ramsey Gas Company, 482
Rating and Valuation Bill, 519, 614
Redheugh Colliery for Sale, 518
Reductions in Price, 191, 193, 326, 384, 613, 753, 973
Rees and Hugill, Messrs., on Refractories, 745
Refractory Materials—
An American Institute of, 314
Analysis of, 842
Green, Mr. A. T., on, 745
Hugill and Rees, Messrs., on, 745
Mitchell, J. & W. B., Messrs., on, 746
Rhead and Jefferson, Messrs., on, 745
Theobald and Green, Messrs., on, 746
Renfrew Gas Works, 379
Rennett, Mr. D., on Smoke and Health, 376
Research—
Aeration of Burners, 880
Benzole, 363, 654
Cast Iron, 1023
Leeds University Gas Plant, 898
Specific Gravity of Gases, 891
Retorts—
Blow Gases for Heating, 225
Vertical—
Dempster-Toogood, 367
Evolution of, 248, 367
Rhead and Jefferson, Messrs., on Refractory Materials, 745
Rhyl Gas Undertaking 606
Riscavoid, 262
River Pollution, The Tar and Bitumen Question, 366, 483
Riveter for Holder Cups, 109
Roads—
Damage to Gas Pipes through Faulty Filling, 677
Tar Treatment of, and Fisheries, 483
Tar *v.* Bitumen for, 360, 366
Robert, Mr. C. M., on Heating by Gas at Los Angeles, 314
Robinson, Mr. F. H., on Gas as a Public Service, 672
Robinson, Mr. R. L., on the Possibilities in Bye-Product Recovery, 965
Rochdale Corporation and Electricity Preference, 719, 748
Rochdale Gas Undertaking—
Bill, 130
Resignation of Mr. T. Banbury Ball, 719, 722, 748
Rogerson, Mr. F. W., on The Cost of Freight Transport by Railway, 532
Romford Gas Company's New Holder, 606
Ross, Mr. E. G., on Electric Cooking, 520, 652
Rotarians and Gas Service, 382
Rotherham Gas Undertaking, 387, 615
Royal Institute of Public Health, 731
Rutter, Mr. C. H., on A Century of Gas Making, 681

St. Dunstan's After-Care Organization, 230
Safeguarding of Industries Act, 610, 678, 748, 970
Safety First Official Journal, 126
Sales Propaganda, Mr. H. D. Madden on, 721, 737
Salford, Attack on Gas-Fires at, 106
Sandy Gas Company, 682
Santos Improvements Company, Ltd., 323
Sauton's, Mr. G. H., Meter Connection Protector, 236
Schilling, Herr H., on Analyzing Refractory Materials, 842
School Lighting, 543
Scottish Gas Undertakings and Section 1 of the Gas Regulation Act, 516
Scottish Junior Gas Association—
(Eastern District.)
General Business, 257
Presidential Address of Mr. R. L. Laing, 257
Secretaryship, 226
Visit to Leslie and Markinch Gas Works, 656
(Western District.)
Blakey, Mr. R. F. W., on Thermal Balance Sheets, 124
Council Members, 464
M'Intyre, Mr. J., on Selecting and Testing Wrought Iron Tubes, 124
Smith, Dr. E. W., on Current Topics, 315
Visit to Renfrew Gas Works, 379
Seabrook, Mr. A. Hugh, on Combination Gas and Electricity Supplies, 380
Sedgley Gas Undertaking, 613
Seltzer, Mr. L. W., on the Chrisman Down Run Process, 311
Sentry Gas Fires, 664
Service Cleanser, The Abbirko Suction, 1026
Shale, Oil, for Gas Manufacture, 319
Shares and Stocks—
Market Reports, 71, 135, 192, 264, 325, 386, 484, 545, 616, 684, 754, 972, 1036
New Issues, &c., 69, 193, 261, 262, 263, 322, 324, 387, 479, 483, 546, 610, 615, 683, 964, 1035
Shatwell and Graham, Messrs., on The Hydrogenation and Liquefaction of Coal, 242
Sheffield Gas Company, 72, 842, 1029
Sheffield Illumination Society, 72
Shell Flakes, Gas Used in Producing, 241
Shelley and Shepley Gas Light Company, 173
Shoreham Harbour Bill, 677
Showrooms—
Coke and Sulphate in, 721
Descriptions of, 234, 462, 738, 1020, 1024
Shrewsbury Gas Light Company, 173, 612
Silica Gel and Benzole Recovery, 363
Simon Pneumatic Handling Plant for Oxide, 527
Singapore Gas Undertaking, 543
Sliding Scale, Electrical Industry and the, 66
Smethwick Gas Undertaking, 193, 675
Smith, Dr. E. W., on—
Cultivation of Coke Markets, 365
Current Topics, 315
Smoke Abatement—
American Gas Industry and, 36
Brereton, Mrs. Cloudesley, on, 731
City Medical Officer's Views on, 543
Czecho-Slovakia and, 735
Daley, Dr. W. A., on, 615
Editorial Comments, 30
Hartley, Dr. H., on, 376
M'Hugh, Mr. F. G., on, 116
Owens, Dr. J. S., on, 178
Rennett, Mr. D., on, 376
Smokeless Fuel Question in Parliament, 473
Thomson, Dr. C. S., on, 650
Whiteford, Mr. J. H. G., on, 46
Society of Arts, Owens, Dr. J. S., on Modern Atmospheric Conditions, 178
Society of British Gas Industries—
Annual Dinner, 599
Council's Visit to Manchester, 377
Editorial Comments, 647
General Business, 593
Golf Competition, 681
Presidential Address of Mr. D. Milne Watson, 595, 647
Society of Chemical Industry—
Bone, Prof. W. A., on The Constitution of Coal, 240
Chemical Engineering Group, 669
Hackford, Mr. J. E., on Gas from Heavy Oil, 532
Lander, Dr. C. H., on Smokeless Fuel and Oil, 242
Lessing, Dr. R., on the Inorganic Constituents of Coal, 175
Membership, 109
Parrish, Mr. P., on Spent Oxide and Spent Oxide Burners, 177
Reports of Progress of Applied Chemistry, 125, 318
Walker, Mr. F. H., on The Sampling of Coal, 470
Society of Engineers' Pamphlet on Preparing a Tender, 460
Solihull Gas Company, 968
South African Lighting Association, 679
South Metropolitan Gas Company—
Bill, 136, 387, 473, 534, 536
Centenary Celebrations, 305
Increase in Price, 172
Large Coke Contract, 446
Launching of the S.S. "Redriff," 472
London County Council and the Basic Price, 131, 189
Official Tests, 322
Operatic Society, 324
Visit of the Institution of Gas Engineers to the Chemical and Physical Departments, 963
South Midlands and Berkshire Electric Light and Power Company, 1018
South Suburban Gas Company—
And Co-Partnership, 750
Official Tests, 322
Standard Price, 546
Southampton Gas Light and Coke Company, 261, 969, 1024
Southend Gas Company, 134, 479
Southern Counties Electric Light and Power Company, 31, 584
Southern District Association of Gas Engineers—
Editorial Comments, 27, 29
General Business, 37
Presidential Address of Mr. P. G. G. Moon, 27, 40, 117, 126
Visit to the Bournemouth (Pitwines) Gas Works, 732, 841
Southport Gas Undertaking, 108
Spalding Gas Undertaking, 612
Specific Gravity of Gases, 879
Specification for Internal Fittings, 602
Speck, Mr. T. R., on Furnace Design and Performance, 182
Spencer-Bonecourt-Kirk Town Gas Fired Boiler, 59
Spontaneous Combustion of Coal, 447
Springs, Gas for Tempering, 258
Stafford Gas Undertaking, 541, 968
Statutory Gas Companies and Electricity Orders, 360, 476
Statutory Gas Meter Inspectors' Association, 72, 1030
Steam Raising Problems, 193
Stockton Gas Undertaking—
Coal Contracts, 387
Haverton Gas Works Purchase Question, 129
North of England Association Visit, 519
Stoke-on-Trent Gas Undertaking, 134, 136, 387
Strabane, Price of Gas at, 753
Stretford and District Gas Board, 613
Stretford and District Gas Company—
Calorific Value, 1032
New Works, 915, 1029
Subsidies, Government, and the Gas Industry, 259
Suffocation by Gas, 387
Sugg & Co.'s Works Visited by Engineers, 57
Sulphate of Ammonia—
As a Fertilizer, 193
Exports, 108, 303, 584
In Gas Showrooms, 721
Summer Time, 30
Sunbeam Gas Fire, 379
Super Centrifugal Engineers' Tar Dehydration Process, 123
Surplus Heat (*see* Waste Heat)
Sutton Gas Company, 1032
Swanage Gas Company, 361
Swansea Gas Light Company, 56
Swindon United Gas Company, 69
Synthetic Ammonia and Nitrates, Ltd., 541
Syphon, Installing an Under Water, 592

T. I. C. Tar Dehydration Process, 254
Tamworth Gas Light and Coke Company, 136
Tar—
Dehydration of Water Gas, 123
Exports, 108
Oils, Refining of Crude, 669
Position of, 592
T. I. C. Dehydration Process, 254
Treated Roads—
Exhibit at the British Empire Exhibition, 460, 465, 729
Fisheries and, 360, 366, 483
Versus Bitumen for Road Treatment, 366, 839
Tavistock Lighting, Coal, and Coke Company, Ltd., 193
Tawe Valley Gas Company, 477
Taylor, Mr. G. S., on Safeguarding Gas Engines, 241
Tayport Gas Undertaking, 304
Team By-Product Coke Company, 262
Telephone Operators, Blinded Soldiers as, 230

Tender, Preparing a, 460
Testing, Calorific Value and, 528
Theobald and Green, Messrs., on Refractory Materials, 746
Thermal—
  Balance Sheets, 124
  Basis, The Economics of Gas Production on the, 943, 966
Thomson, Dr. C. S., on Smoke Abatement, 650
Tin Decorating by Gas, 746
Todd, Mr. Duncan, on Co-Partnership, 260
Todmorden Gas Undertaking, 31
Tokio Gas Works, Effect of Earthquake on, 231
Toluole Extraction, War Office Claim by Dr. W. B. Davidson, 321, 381, 584
Torquay and Paignton Gas Company, 189, 1035
Tottenham District Light, Heat, and Power Company—
  Gas for Housing Schemes, 387
  Official Tests, 322
  Stock Issue, 483
Towyn Gas Company, 477
Trade Facilities Act, 519
Trade Notes, 69, 133, 263, 323, 385, 482, 546, 613, 682, 752, 1033
Trenching Machine, The Ford, 533
Troon Gas Undertaking, 263
Truro Gas Company, 683, 1035
Tully, Mr. C. B., on Gas Stocks as Gilt-Edged Investments, 367
Turbines—
  Coke Breeze Furnace for, 48
  Gas, 365

Uckfield Gas and Electricity Company, 476
Unaccounted-for Percentages and Low Calorific Value Gas, 301, 473

Vauxhall Colliery Run by Miners, 172, 517, 1017
Vince, Mr. E. P., on Local Publicity, 530
Vowles, Mr. Hugh P., on Electric Power Plant for Gas Works, 179

Wakefield Electricity Department and the Supply of Electric Appliances, 326, 477
Wakefield Gas Works Visited by the Yorkshire Junior Gas Association, 746
Wales and Monmouthshire District Institution of Gas Engineers—
  Editorial Comments, 721
  Madden, Mr. H. D., on Sales Propaganda, 721, 737
  Muir, Mr. D., on Methods Adopted to Deal with Leakage in Colliery Districts, 742
Wales and Monmouthshire Junior Gas Association—
  Addresses—
    Bacon, Prof. F., 57
    Illingworth, Dr. T. R., 741
    Johns, Mr. W. H., 56
  Annual Meeting, 468
  General Meeting, 668
Walker, Mr. F. H., on Coal Sampling, 470
Wandsworth, Wimbledon, and Epsom District Gas Company—
  Death of Mr. H. E. Jones, 32, 241
  Directorate, 226
  Increase in Price, 136, 172
  Official Tests, 322
Warner Low Temperature Retort, 185
Warrington Gas Undertaking, 447, 585
Warwickshire and South Midland Electricity Supply Corporation, 445
Waste (or Surplus) Heat Recovery—
  Booth, Mr. W. Newton, on, 49
  Parker, Dr. A., on, 180
  Seabrook, Mr. A. Hugh, on, 107
Water Gas, Chrisman Down-Run Process, 311
Water Heating by Electricity, 585, 675, 724, 746, 1020
Waterloo Bridge, The New, 722
Watson's, Mr. D. Milne—
  Address to the National Gas Council, 658
  Presidential Address to the Society of British Gas Industries, 581, 595
Weaver, Sir Lawrence, on Exhibitions and the Arts of Display, 725
Wellington (N.Z.) Gas Company, 133
Wells Gas Light Company, 189, 483
Welsbach Light Company, 324
West's, Mr. F. A., Presidential Address to the Eastern Counties Association, 237, 301, 473, 534, 606
Westminster City Council Bill, 187
Weyman's, Dr. Geoffrey, Address to the North of England Gas Managers' Association, 649, 665
Weymouth Electrical Exhibition, 111
Weymouth Gas Works, Novel Gasholder Extension at, 588
Whatmore, Mr. A., on Steam Raising Problems, 193
Wheeler, Major F. Cornelius, on Co-operation between the Gas Industry and the Trader, 729
Wheeler, Prof. R. V., on Furnace Heating, 174
Whessoe Foundry and Engineering Company, Ltd., 680, 751
Whiteford, Mr. J. G. H., on Atmospheric Pollution Remedy, 46
Whitwell, Price of Gas at, 72
Wilkinson, Mr. G., on Electricity Tariffs, 447
Willenhall Gas Company, 173
Williams, Mr. J. N., on Town Gas for Boiler Firing, 58
Williams, Mr. R. B., on Preventing Corrosion, 256
Wills, 461, 522, 744, 1020
Wilton's Patent Economy Jets for Forced-Draught Furnaces, 469
Winchester Water and Gas Company, 261
Withnell and Brinscall Gas Undertaking, 326
Wollaston Producer, The, 917
Wolverhampton Corporation Bill, 131
Wolverhampton Gas Company, 131
Wood, Russell, and Co., Sentry Gas Fires, 664
Woodall-Duckham Models at the British Empire Exhibition, 460
Woolwich Arsenal Visited by London and Southern Junior Association, 126
Workington Electric Power Company, 526
Workington Gas Undertaking, 753
Worthing Gas Light and Coke Company, 387, 477, 681

Yarmouth Electricity Supply Undertaking, 229, 304
Yorkshire Junior Gas Association—
  Presentation to the late Secretary, 1026
  Visits—
    Blakeborough and Sons' Works, 318
    Wakefield Gas Works, 746
Yorktown and Blackwater Gas Company, 67, 387, 546

REGISTER OF PATENTS.

[The names printed in italics are those of persons by whom patents have been communicated.]

Anderson, J.—Gas Meters, 260 (2)
Bakhuizen, W.—Gas Burners, 676
Clapham, T. A., and Clare, R. J. W.—Purifier Lids, 1029
Cobb, J. W., and Hodsman, H. J.—Purification of Gas, 747
Cooke, A. G., and Phillips, B. C.—Dry Meters, 186
Curtis, S. P.—Carbonization, 260
Dempster, R. & J., Ltd., and Hill, W.—Gas Tight Disc Valves, 536
Dempster, R., & Sons, Ltd., and Woodhead, C. J.—Discharging and Charging Retorts, 380
Dempster, R., & Sons, Ltd., Horsfall, J. E., and Lumb, H.—Rotary Purifier Valve, 535
Dempster, R., & Sons, Ltd., and Toogood, H. J.—Producer and Combustion Arches, 535
Dougall, J.—Prepayment Mechanism, 535
Drakes, Ltd., and Drake, J. W.—Retort Discharger, 127
Drakes, Ltd., Walker, A. B., and Walker, A.—Screening Coke, &c., 320
Eickworth, R.—Gas-Fired Firetube Boiler, 259
Ewart, J. W.—Geysers, 1030
Fox, T., and Robinson, S.—Prepayment Mechanism, 535
Gausden, A. H.—Geysers, 260
Gibbons Bros., Ltd., Marle, M. V., and Walter, C. M.—Furnaces, 186, 536
Gill, H. A.—Manufacture of Sulphate, 1029
Glover, T., and Wayte, W. H.—Gas Ovens, 1030
Gumperz, A., and Meyer, A.—Mantles, 534
Harrison, J. F., and Peebles, W. C.—Pressure Relief Valve, 380
Helps, G.—
  Burners, 260
  Gas Cookers, 260, 321
  Gas Taps, 186
Huessener, K.—Regenerative Gas Furnaces, 259
Humphreys and Glasgow, Ltd., and Stelfox, J. C.—Control of Water Gas and other Cyclical Processes, 128
Imray, O. Y.—Carbonization, 260
Keith and Blackman Co., Ltd., and Keith, G.—Governor with Liquid Loading, 320
King, W. E., and the Gas Meter Co., Ltd.—Automatic Lighting Mechanism, 535
Kirkewhite Engineering Co., Ltd., and Goldspink, G. E.—Gas Meters, 128
Kirkham, Hulett, and Chandler, Ltd., Hersey, S., and Stokes, F. W.—Washer Scrubbers, 260
Kohlenscheidungs G.m.b.H.—Low-Temperature Distillation, 534
Koppers Coke Oven Company, Ltd.—Coke Handling Plant, 259
Koppers Company, Ltd.—
  Coke Ovens, 259
  Coking Batteries, 126
L'Air Liquide Sté. Anyme. pour L'Etude et L'Exploitation des Procédés Georges Claude—Purification of Coke Oven Gases, 259
Liggins, J. W.—Gas Ovens, 535
Mackenzie, M., Sylvester, J., and Outwin, E.—Ascension Pipes, 186
Main, R. & A., Ltd., and Richardson, A. H.—Locking Plug Taps, 1030
Mellersh-Jackson, W. J.—Coke Ovens, 259
Metropolitan Gas Meters, Ltd., and Forster, J. D.—Coin-Freed Gas Meters, 1029
Neath, J., and Chaney, W.—Manufacture of Coal and Water Gas, 126
Potts, H. E.—Purifying Crude Ammoniacal Liquor, 321
Regenerative Coal Gasification System, Ltd., Travers, M. W., and Clark, W.—Producers, 18
Rigby, J.—Coke Separator, 966
Ross, D., Weiser, R. F., and the British Mannesmann Tube Co., Ltd.—Testing Pipe Joints, 127, 186
Rude, J.—Carbonization, 186
Schar, F., and Theumar, R.—Safety Cocks for Gas Burners, 259
Sellars, B. C.—Preparation for Repairing Retorts, 535
Simpson, J. F., and Peebles, W. C.—Gas Governors, 127
Smith, E. W., and Smith Meters, Ltd.—Coin-Freed Mechanism, 1029
Spencer, J. A.—Grids for Purifiers, 747
Sté. des Fours à Coke Semet Solvay et Piette—Manufacture of Sulphate, 1029
Stinnes, Z. M.—Purifying Crude Ammoniacal Liquor, 321
Sugg, W., & Co., Ltd., and Sugg, P. H.—Wash Boilers, 676
Sutherland Meter Company, Ltd., and King, F. H. W.—Prepayment Meters, 380
T.I.C. Research Co., Ltd., Duckham, Sir A. M'D., Rider, D., and Watts, J. S.—Heat Treatment for Distilling, Drying, or Carbonizing, 187
Thorp, F., and Parkinson and W. & B. Cowan, Ltd.—Wet Meters, 259
Todman, J. C., and Metcalfe, F. E.—Apparatus for Lighting Gas, 747
Urbain, E.—Purification of Gases, 534
Vicars, E. L.—Gas-Heated Bakers' Ovens, 966
Whitwell, G. E.—Water Gas Production, 259
Woodall, Duckham, and Jones (1920), Ltd., and Sir Arthur M'D. Duckham—Extraction of Coke from Vertical Retorts, 320
Woodall-Duckham (1920), Ltd., and Duckham, A. M'D.—Blending and Briquetting for Vertical Retort Operation, 1029
Zuyderhoudt, P. C.—Low-Temperature Carbonization, 259

230,705. Ammoniacal Liquors, Purification of Crude—Potts, H. E., 321
229,863. Ascension Pipes—Mackenzie, M., Sylvester, J., and Outwin, E., 186
231,943. Automatic Lighting Mechanism—King, W. E., and the Gas Meter Company, Ltd., 535
233,054. Bakers' Ovens, Gas-Heated—Vicars, E. L., 966
233,508. Blending and Briquetting for Vertical Retort Operation—Woodall-Duckham (1920), Ltd., and Duckham, A. M'D., 1029
232,480. Brick for Muffle Furnaces—Gibbons Bros., Ltd., and Marle, M. V., 536
Burners—
211,473. Bakhuizen, W., 676
Carbonization—
230,281. Imray, O. Y., 260
228,763. Rude, J., 186
229,880. Zuyderhoudt, P. C., 259
229,042. Coal Gas and Water Gas Manufacture—Neath, J., and Chaney, W., 126
Coke—
230,518. Extraction from Vertical Retorts—Woodall, Duckham, and Jones (1920), Ltd., and Sir Arthur M'D. Duckham, 320
218,654. Handling Plant—Koppers Coke Oven Company, Ltd., 259
230,632. Screening Apparatus—Drakes, Ltd., and Walker, A. B., 320
233,200. Separator—Rigby, J., 966
230,167. Coke Ovens—Mellersh-Jackson, W. J., 259
224,863. Coke-Oven Gases, Purification of—L'Air Liquide Sté. Anyme. pour l'Etude et l'Exploitation des Procédés Georges Claude, 259
215,306. Coking Batteries—Koppers Company, 126
Cookers—
230,526, 230,921. Helps, G., 260, 321
232,514. Disc Valves, Leather-faced—Dempster, R. & J., Ltd., and Hill, W., 536
231,220. Discharging and Charging Retorts—Dempster, R., & Sons, Ltd., and Woodhead, C. J., 380
216,151. Firetube Boiler, Gas-Fired—Eickworth, R., 259

EDITORIAL NOTES.

HENRY EDWARD JONES.

THE announcement in last week's "JOURNAL" of the death of Mr. Henry Edward Jones has been received throughout the gas industry with profound sorrow, for he had an individuality in our midst which endeared him to us all. The members of the family have the consolation of knowing that their grief is shared by countless friends in the industry. The end was unexpected. We all knew that our friend had journeyed through his eightieth year; his intimates realized that he was about to complete his eighty-second year. But the vigour of mind and body to the finish seemed a contradiction of the four-score years and more. The passing fitted the life—it might almost be said to have been characteristic of it; for until just before the silent call, Mr. Jones had been pursuing the activities of, for him in latter years, a normal day. He had in early morning been interesting himself in business matters associated with at any rate one of the gas undertakings with which he was administratively concerned; he had had a run with the Essex hounds—the greatest of his pleasures and recreations. Only the space of thirty minutes parted usual activity and final rest.

A vacant place has been made in our midst which cannot be filled; for we know of no one in the industry possessing the same composite traits as our departed friend. The length of personal experience in all the ramifications of the gas industry, the fundamental and detailed knowledge of its affairs, the devoted application of that knowledge in administrative and professional capacity, taken together, remained almost without rival as the little group of front rank contemporaries left the scene of their labours. Mixed with those qualities and the wisdom with which they were used and applied, were wit and an irrepressible cheerfulness—even in gloomy and stressful days. We have known that Mr. Jones could be brusque and plain spoken; we always knew that what he said he meant and what he meant he said. Never, however, did he hesitate to praise when deserved. He was a sportsman and large-hearted. Those who were trained under him for the gas profession—his "boys"—have to thank him for his insistence on application and discipline; and among them we do not know of a single one who in after life did not thank their "lucky stars" that they were brought up on the engineering and managerial regimen of "H. E. J." They ever afterwards looked upon him as their guide, philosopher, and friend; and he was the first to whom they turned when in need of counsel. On the several Boards of which he was Chairman or an ordinary member—mostly the former—his fellow administrators will sadly miss him. His sound common-sense, his technical advice, his outspoken criticisms, his quick discernment and ability to make prompt decisions, and his plainness in expressing his views, together with his fine geniality, caused his colleagues to have an admiration for him of a nature which age and experience alone could not have commanded. In administrative work he progressed with time's changes; he never allowed the traditions of the past to cling about him and impede his movements. He was always for advance. "Cheap gas" was a favourite term which in his practices was translated into reality—anyway, to the utmost extent to which he could carry it in the circumstances of the times. In the quest for means of realizing this dominant object, and in his practices, he was keen on securing and maintaining a low capital account. A low capital account and cheap gas were close companions in his mind and actually. But he did not seek a low capital per unit of production by starving works or purchasing inefficient plant. There was a strong belief in the wisdom of spending to secure efficiency; but he found the point where economic efficiency ended, and declined to pay an uneconomic price for any efficiency beyond.

Above all things Mr. Jones was an engineer; and he was proud of his profession—not only so, he was jealous of it. But pride and jealousy alone will not take a man to the highest pinnacles of such a profession. There must be ability of pronounced and varied order. That ability was a possession of our late friend which took him to a foremost place in the profession. Not only gas engineers, but his compeers in other branches of engineering recognized his talent; and they were proud—as he felt the distinction and the honour—to have him in the Presidential Chair of the Institution of Civil Engineers. As a consulting engineer he had a large practice, even before he relinquished the office of Chief Engineer and General Manager of the Commercial Gas Company, and went to Westminster. His advice was much sought; and his presence in the Parliamentary Committee rooms in connection with Private Gas Bills was constant in the old days, before the war and Special Orders interrupted the former normal course of things. In the past half century, there has been no great gas fight affecting the general interests of the industry in which he has not been concerned—always on the side of the industry, never against it. He was one of the gas engineering and administrative experts whom eminent leaders at the Parliamentary Bar preferred to have with and not against them. There was nothing subtle about him or his evidence. Its quality and soundness, its openness and frankness, impressed and were persuasive, and carried weight with the Committees of both Houses. A great power in the industry has finished its course.

We look back over a considerable stretch of years in which "H. E. J." has had such prominent place and (until now) an unceasing part in the work of the industry. So inseparably associated with gas affairs has he become in our minds that it is difficult to believe that he is no longer with us. We shall all miss him; but, while sorrow at his loss will remain, his gifts and charming characteristics, and what he has taught and done, will be imperishable and happy memories with those of us among whom he has lived and moved. *Vale!*

A Matter of Pressing Importance.

THE Presidential Address to which the members of the Southern District Association of Gas Engineers and Managers listened last Tuesday week was the work of an observer and a student of the trend of things in the gas industry, and withal a keen worker in its interests. Mr. Philip G. G. Moon, the Engineer and General Manager of the Bournemouth Gas and Water Company, in preparing the address, concentrated his thoughts on those affairs that are of immediate outstanding concern to the industry; and he led up to them by referring, with modesty but gratification, to the remarkably fine record that the Bournemouth Company can show of progress in their gas supply business. This has necessitated the construction of new works at Pitwines, which incorporate several imposing features of engineering interest, about which

there will be an opportunity of saying more on a future occasion. The record of gas progress at Bournemouth has about it a robust and genial aspect; but it is merely a reflection of what is going on all over the country, subject to the limitations set by local conditions. However, the prosperity in regard to gas sales (which, it is hoped, will not be interrupted by the current set-back in the markets for secondary products) must not cause us to close our eyes to, or simply to smile complacently upon, what is going on around us in the political world, aided and abetted by both subterranean and open fostering by our principal competitors, who are trying, on congenial soil, to obtain an advantage to the disadvantage of the gas industry. It may be considered by some that the far higher efficiency of the gas process in relation to the utilization of our fuel supply is a sufficient palladium against anything that can be done through political avenues in favour of our electrical competitors. That is partially, but by no means completely, true. Therefore it must be the business of the gas industry in the first place to do what it can to resist the conferring of any exclusive advantage on the electricity industry which, if there is realization, must in some degree (to what extent no one can predict) be to the detriment of the gas industry, if it takes the form of preferential treatment—say, through subsidization. But apart from direct effects, we detect beneath the words in the address of the President and in the remarks by Sir Arthur Duckham at the close of its reading, an appeal for the consideration of the matter from a higher point of view—and that a national one—by an industry which is, through the utilization of coal, doing immeasurably more in the service of the country than are the public electricity supply undertakings (apart from traction). When an industry such as ours sees that mistakes are being made, when we have within our keeping the proof that they are mistakes, and are the fruits of misconception and misguidance, then it is a duty and a responsibility to correct them. If we do not do this with boldness and perseverance, if we lose an opportunity of promulgating the truth, then we are betraying our trust, and should deserve all the unwelcome results which lethargy brought upon us.

The President pointed out that there are many political men who do not realize the more important place occupied by gas than electricity in the economy of the country's fuel supplies, while acknowledging that electricity has a sphere of service which it can and does fill with advantage to the community, but real advantage can only be within that sphere. The ignorance in this regard that prevails among some politicians is well illustrated by a privately expressed statement of a prominent member of Parliament, that he has no place for the consideration of anything but electricity where light, heat, and power are concerned; also by the book on "Coal and Power" which bore the name of Mr. Lloyd George; by the attitude of the late Labour-Socialist Government; as well as by certain expressions of opinion by present Ministers. The facts as to the efficiency of the utilization of coal by the gas process and by the electrical, as vividly presented in Mr. Moon's address, are unknown to the bulk of our legislators; and therefore no wonder that the glamour which has been so sedulously thrown round electricity has taken hold of them. The gas industry cannot altogether exonerate itself from blame in this regard. It is true that we had an invaluable report from Sir Dugald Clerk and Professors Smithells and Cobb which demonstrated the comparative efficiencies of the two processes; but has sufficient widespread use been made of that report, or of plainly stated data such as are found in Mr. Moon's address? He takes the figures applying to electricity supply in this country in 1923. The fuel used amounted to 7,356,757 tons, and from that coal the equivalent of 169·4 million therms was produced—the average consumption of coal being 3·32 lbs. per kw.h. Assuming that coal had been used at twice the efficiency, the output in therms would have been only 338·8 millions. Using that same quantity of coal in the gas process, at 70 therms per ton 515 million therms would have been produced as gas and 989 million therms as coke, to say nothing of tar and sulphate of ammonia. The coke, if turned into producer gas, and used for the generation of electricity, would generate 2747 million units of electricity. "The moral," says the President, "is obvious." Do our legislators know these facts? Have they been placed before them in a manner which they as laymen in these matters can understand? We think not.

We have to get well beyond what has been done. Sir Arthur Duckham says that while the gas industry has very fine specialized propaganda, he does not believe that any of us have formulated in our minds how a programme of fuel development in the country should be put forward from the national point of view. He says, as is also stated in the address, that a small Committee of distinguished men have been appointed for this purpose. This is good and satisfactory; and the hope he expresses, that the Committee will come to really sound conclusions, will, we are sure, run through the industry, because up to now the fuel problem has not been handled soundly in this country—it has only been treated from a very narrow point of view. But the industry has to get its economic facts home; has to show the country that a greater extravagance in providing for its heat requirements is simply a flight to further national uneconomy and inefficiency. Mr. Moon is favourable to very broad action. His opinion, which will be powerfully backed in the industry, is that co-ordinated effort is required, and he proceeds:

> I think the time is over-ripe for the formation of a permanent Committee drawn from the leading administrators, engineers, scientists, and publicists of the industry, whose definite duty it should be to impress upon the country by means of lectures by eminent scientists, by newspaper articles and pamphlets, and by representations to all political parties, the fundamental thermal facts of gas manufacture and electricity generation and their effect upon the nation's fuel resources. I hope my remarks will not be interpreted as in any way belittling the great and growing importance of electricity and the part it plays in the home and industrial life of the nation.

Those remarks were written before there was knowledge on the President's part as to the appointment of a Committee; but they show the feeling of one influential engineer, and that it is not solitary is testified by the action of the Manchester Institution of Gas Engineers in addressing a communication to the other Associations regarding the much-talked-of subsidizing of the electricity industry out of national funds, as well as by the resolution passed at the largely attended Southern meeting. The latter recorded that the members had heard with pleasure of the formation of a Committee of distinguished men to consider the position; and it urged that the Committee should take the necessary steps to impress the position upon the country by means of lectures, newspaper articles, &c., and most particularly by putting the true economic facts with regard to both industries before Members of Parliament. It was also submitted that the latter action should be taken without delay, as the members of the Association feel that, while the gas industry has nothing to fear from the fair competition of the electrical industry, the booming of the latter for political purposes, if allowed to proceed further without strong opposition, can only end disastrously for the country as a whole. This shows that the gas profession will be prepared to give the strongest possible support to a full and vigorous policy which will have counteractive effect upon political misconceptions and proposals in this regard.

That the matter requires speeding-up and prosecuting in a broadcast manner is seen from the debate on unemployment in the House last Thursday. In the febrific imaginations of some of our politicians, electrical development is the cure for all our troubles. On the occasion referred to, Sir A. Steel Maitland said: "The real scheme, *which "is profitable on every conceivable ground,* is the electricity scheme. That scheme is being pressed forward "as rapidly as possible, but no human being could get "through a scheme of that elaboration in a short time." Does that reflect the views of the whole Government? We do not know; but the Minister of Transport has been talking of electricity a good deal in public lately in a somewhat similar confident way. The case for the widespread promulgation of genuine facts is beyond dispute, so that a halt may be called in order to examine the facts from

a national point of view, and not in the partial, incomplete, and unsatisfactory way which is at present being pursued in Government circles. The National Gas Council are moving. One thing we would strongly emphasize is that whatever is done the facts must be presented in a manner which can be popularly understood. In this respect, the clarity of Mr. Moon's data is a model for further and wider application.

Chemical Manufacturers and the Gas Industry.

There are two points about their Bill in Parliament upon which the Gas Light and Coke Company may be heartily congratulated. The measure proposes the largest individual amalgamation which has ever taken place in the gas industry, by the incorporation of the Brentford Gas Company in the gigantic premier undertaking. In the large area which will thus be created under the one gas-supply jurisdiction, there are numerous local authorities, who without doubt have given to the scheme the minutest scrutiny aided by expert advice, with the result that, although there were originally 35 petitioners against the Bill, none put in an appearance before the House of Commons Committee last week. The only opponents were the Alkali Manufacturers' Association, one of whose main ambitions in life is to shackle the gas industry as much as possible in order to serve their own ends and interests, instead of those of the millions of gas consumers of the country. The first matter for congratulation to the Gas Light and Coke Company therefore is the complete endorsement given by the numerous local authorities to the scheme of amalgamation. The second point for felicitation is that the Alkali Manufacturers' Association did not gain anything by their interference. If leading Counsel for the Company (Mr. H. P. Macmillan, K.C.) is correct in his surmise, it is necessary to look deeply beneath the surface to find the real reason why the Association were there at all; and the suggestion is that their move has on this occasion some connection with the Deuchar litigation, which seeks to prevent the Gas Light Company making caustic soda for the purpose of working-up their own secondary products. In that the chemical manufacturers have failed in the High Court and the Court of Appeal, and, pursuing the Company to the fullest extremes, they are now taking the case to the House of Lords. The idea was, if they could succeed in their desire before the Commons Committee, a useful advantage would have been obtained which would have helped them in the litigation.

The position is almost farcical. The Brentford Gas Company in their Gas Order of 1924 had the one-third residuals purchase clause placed upon them, with the usual proviso that they may "purchase from other gas undertakers and elsewhere, and use, the materials required to work up and convert the residual products so arising from their own manufacture of gas, or purchased as aforesaid;" but "shall not manufacture chemicals exclusively from raw materials purchased from sources other than gas undertakings or in the manufacture of which the use of residual products produced by the Brentford Company or purchased from other gas undertakings is merely subsidiary." This clause the Gas Light Company proposed should be repealed, on the ground that the Bill intended that the Brentford area of supply should come under the legislative code of the Gas Light Company, which Company have no power to purchase secondary products from other concerns, and they do not desire it. They have sufficient of their own. The chemical manufacturers wished to retain and not repeal something that the Gas Light Company do not want, even though the clause only applied to the Brentford area. This being so, there was a motive, which we think was fairly well revealed by the proceedings. To have retained the clause would have complicated matters; the object of the Bill being centralization and concentration, and not to make the conditions of working more complex in the interests of the chemical manufacturers. But it was very clear before the discussion ended that it was the proviso, and not the one-third restriction, which was the real objective of the opposition. In the view of the Governor of the Company (Mr. D. Milne Watson) if the proviso was placed upon the Company, it would deprive them of existing powers on the faith in which large sums of money have been expended; and, among other things, it would have the effect of preventing their manufacturing caustic soda for the working-up of their own residuals. The chemical manufacturers do not appear to have had the candour to acknowledge at the outset what was the exact object of their opposition; but, before the hearing concluded, their Counsel admitted that the proviso at the end of the clause was the thing that would handicap the Company. Truth will out; and so the surmise of Mr. Macmillan was correct. The Committee very properly sent the chemical manufacturers empty away. It is a singular thing that Parliament should ever allow any interference with the carrying on of gas undertakings to the best advantage in the public interests, in order to further the private interests of the chemical manufacturers. It is absurd to contend that the liberty enjoyed by them should not be allowed to gas companies as public utility concerns; inasmuch as the maximum economy and efficiency at which the latter can be worked is, through the sliding-scale, to the advantage of the public.

New Gas Producing Plant and Old Purification Methods.

The gas profession, as is well known, has been deeply indebted to a succession of occupants of the office of Chief Alkali Inspector and the members of their staff. The happy relations that have always existed between them and the chief technical officers of gas undertakings are due to the reciprocal feeling that both are out for the purpose of securing the highest efficiency in the operations which come under the surveillance of the Chief Inspector's Department, in view of the fact that, through such efficiency, the conditions can be fully preserved which it is the main function of the inspectors to see are duly observed. In such matters it is an excellent tradition of the Department that it is always better to realize the end by good understanding than by autocratic control or the application of compulsory method. The latter is only exercised when there is deliberate and flagrant evasion of conditions and regulations. It was a happy thought which led to the invitation to Dr. T. Lewis Bailey, the Chief Inspector of Alkali Works, and Mr. F. Napier Sutton to be present at the luncheon of the Southern District Association of Gas Engineers and Managers on Tuesday of last week. In the course of the after-luncheon proceedings, Dr. Bailey proposed the toast of the Association; and in doing so he made a suggestion which we think is worthy of consideration and investigation by gas engineers and chemists.

The work of the Chief Inspector has necessitated his studying gas making in its modern forms; and he says it has led him to the conclusion that gas engineers have been going ahead as fast as they could by altered and improved methods of making gas, but he is rather afraid that, in doing this, they have not considered to the extent they should have done the question of whether the new methods require any modification of the subsequent processes. Dr. Bailey's exact words were: "Gas engineers "have stuck their new methods of making gas on to their "old methods of cleaning it; but is this right? It is a sug- "gestion I throw out; and I think I am justified in doing "so. Is there not a vast field to be explored in the cleaning "of gas—that is, in the treatment of the gas after it comes "from the retorts, and before it leaves the works?" Now that the point has been raised, it has to be acknowledged that during the past decade the composition of gas as it passes from the retort-house in its crude state has been altered considerably with good economic effect, but not always, regarded chemically, in respect of the distribution plant and appliances. Further, the admission has to be made that there has been no definite and general investigation as to whether or not the condensing, washing, and other purification plant and processes are the best that could be devised for dealing with the gas of the present day. The only thing that can be said, apart from other chemical considerations, is that, within the limits of statutory decrees as to purity and quality of gas, testings are now carried out more rigorously than they were beforetimes, and that very little complaint is to-day heard of any infraction of the standards laid down. However, Dr.

Bailey's point is a good one, and deserves thorough investigation to ascertain the answer that should be given to his question, "Is this right?"

Smoke Abatement and Gas and Electricity.

The District Conferences of the "B.C.G.A." have started with a good swing at Leicester and Greenock. A sketch of the proceedings in the former town was given in our columns last week; and an account of the Greenock meeting appears to-day. One thing that particularly strikes us about these conferences is the immense enthusiasm that is shown in the work by the municipal authorities—especially by those owning both gas and electricity undertakings. There is no question that among them there is spreading a strong appreciation of the part they should and must take, to fulfil thoroughly their functions in fostering to the utmost atmospheric conditions which will promote the health of the community and, through enhanced cleanliness, the amenities of the cities and towns over which they have governmental jurisdiction. There is also an extending understanding of the potentialities and the limitations of the rival methods of accomplishing this work. Everything must be done to advance this knowledge; and it is clear from what Mr. F. W. Goodenough said at Leicester that this is one of the salient components to-day in the policy of the Association. The lines of the conferences so far held, and we take it the same will apply to those which are to follow, show this to be so. The knowledge is not confined to the members of municipal authorities; it is gaining ground among the public. But the public, regarded apart from their municipal representatives, look upon heating by gas more from the labour-saving and convenience points of view than from that of atmospheric purity. What is happening among the public is that never in the whole history of the gas industry has there been such a long continuity of high-level demand for gas appliances, and the result is seen in the universal report of a considerable demand for gas, notwithstanding industrial depression. This is going on despite the activity of the electrical people in urging the public to adopt electric cooking and heating.

There are two points in a speech made at the Leicester conference by our friend, Mr. Councillor George E. Hilton, the Chairman of the Corporation Gas Committee, to which we should like to make brief reference. He remarked that there was no doubt that legislation to speed-up smoke abatement was urgently required, though they would have to wait until next session before getting it. We agree as to the urgency, especially if the Bill that is passed empowers—as did the Bill which was on its journey when the late Government relinquished office—local authorities to make by-laws requiring new houses to be provided with cooking and heating arrangements of a non-smoke producing order. But there is no reason why municipal authorities should wait for legislation before actively engaging in work which will assist in bringing about a great reform. The second point is that "at present the annual home consumption of coal is in the neighbourhood of 180 million tons, and of this considerably more than three-quarters is burned in a raw state. When talking of smoke abatement, there is no need therefore to waste time in arguing the merits of gas and electricity. There is ample scope for both to make all the inroads they can upon the 75 p.ct. of the fuel consumption which consists in burning raw coal." In part we agree with Councillor Hilton; in part we do not. We are of opinion that, in the national interests, when talking of smoke abatement it is necessary to consider the merits of gas and electricity in order that a proper perspective may be obtained, and that the country may not be led into making provision for accomplishing a prodigal waste of fuel through the application of electricity to general heating, and thus incidentally rendering the country poorer than it is to-day. There is not ample scope, even in the cause of smoke abatement, for the utilization of more coal at a lower efficiency than now obtains by its use in other ways. The combined thermal losses in electricity generation and transmission are so great that for ordinary heating purposes electricity can never take the place of gas—all it can do is to indulge in a little pretence that it is doing something effective on the outskirts of the work. Moreover, for general heating (being a seasonal and not a continual requirement) it would necessitate provision in generating and transmission plant which would be idle for a large part of the year, and thus another uneconomy which would have to be borne by the electricity undertakings and the consumers—or perchance the ratepayers.

It is no use for the purpose of displaying in public an unprejudiced mind, or a diplomacy having for its object the protection of the feelings of our electrical friends, to indulge in the ignoring of facts, or in the concealment of knowledge. It is because this has been done in the past that misconceptions exist so extensively in the political mind. It is well to look the facts squarely in the face, and, having done so, to accept the position as it is found, and as it can be proved to be. That position is that the treatment of coal by the gas industry presents the largest economy to the nation of any suggested method of attacking the smoke problem; and no words can affect the truth of this. Everybody connected with the gas industry has (to use words culled from the paper of Mr. James Paterson, M.A., at the Leicester conference) "a great civic duty . . . . to lead the people of these islands to the realization of the glorious vision of clean towns and cities, and a healthy population revelling in the enjoyment of pure and unpolluted atmosphere."

Special Benevolent Fund Appeal.

The President of the Institution of Gas Engineers (Mr. J. Ferguson Bell) is making a special appeal on behalf of the Benevolent Fund. It is addressed to those members who so far are not subscribers, and to those who are for increased subscriptions. The Fund has proved of incalculable benefit to many of those unhappily left unprovided for; and, in addition, special grants are made to meet urgent cases of need. At a recent meeting of the Committee of Management of the Fund, fifteen grants were made, which will amount to £517 during the year. The total estimated expenditure will be about £600. The total of the subscriptions received from members last year was only £272, donations £90, and interest on investments £139—giving a total income of £501, so that unless members' subscriptions are increased this year by at least £100, it will be necessary to draw upon reserves, and grants in future will require to be curtailed. This the President knows is not the wish of the members. We trust the appeal will bear good fruit.

Permanent Summer Time.

The Summer Time Bill has been before a Standing Committee of the House of Commons. An unsuccessful attempt was made to alter the period in the measure—the first Sunday in April to the first Sunday in October—to the third Sunday in April and the third Sunday in September. It will be impossible for the Bill to affect the commencement of summer time this year; and therefore the Home Office will issue the customary Order, which will fix the date from the third Sunday in the month—April 19.

Virgin Soil.

Many gas shareholders will have received a well-printed prospectus, containing four pages of wording which is not worth the highly respectable paper on which it is printed. The style is excellent, the substance of the prospectus distinctly thin. The high-sounding title of the new venture is the Southern Counties Electric Light and Power Company, Ltd. The document bears the stamp of the National Scheme for Disabled Men, which term does not necessarily include disabled investors. It is to be a rich Company, with a capital of £46,000, and offices in London, Brighton, Eastbourne, Bournemouth, Exeter—the registered offices being in Bournemouth. All the places named are well supplied with electricity. The £46,000 is divided into 20,000 8½ p.ct. participating preference shares of £1 each, 20,000 ordinary shares of 1s. each, and 2500 first mortgage 7 p.ct. debentures of £10 each. The Company require at present merely a paltry £35,000, for carrying out a contract with the Electricity Finance and Distribution Company, Ltd., of 43, Cannon Street, to buy a plot of land for a generating station for £80 at Sturminster-Newton, to buy from Jenner & Simpson, of Battle, an elec-

tricity undertaking there for £2500, to purchase a piece of land and battery building at Battle for £400, the preliminary expenses due to the Electricity Finance and Distribution Company estimated at £1000, and administrative expenses and cash loans on account of contracts, &c., estimated at £1800, exclusive of legal charges. The preliminary and other expenses, estimated at £4000, amount to more than the sum to be paid for the Battle undertaking! By the way, the urban district of Battle is included in the Extension Order of the Hastings Corporation, now before the Electricity Commissioners. Another contract has been made with the Chagford and Devon Electric Light Company (one, we believe, of the 43, Cannon Street hatchings) to take from them electricity in bulk. If there are fools enough to supply the £35,000, the Company should have a good margin of spare cash. But we do not think that anybody who knows the history of these promotions will put money into such a flimsy affair as this. We see that the dear old Baronet has again been installed in the chair—Sir Charles B. H. Soame. He is on so many "Boards" now, and Chairman of so many, that he cannot have much leisure time. Mann, Martin, Bennett-Calvert, and Brigden are other names on the Board. W. Thompson, of 43, Cannon Street, again figures as the Solicitor, and C. A. Turner & Co. (whose reports as Auditors are consistently favourable to these ventures) have enlarged their clientele by the addition of this Company. Why is it that the name of Eaton does not appear so frequently on these documents in these times as it used to do in other days? Has it lost its magnetic power?

Economy of 20-Ton Wagons.

The economy of 20-ton wagons where they can be used has led to a further concession by the Great Western Railway to users at the South Wales ports. In addition to the rebate of 5 p.ct. allowed off the conveyance rates, the charge for tipping and weighing coal in fully loaded 20-ton wagons at the docks owned by the Company will be at the rate of 6d. a ton (instead of the ordinary charge of 7½d.)—a decided advantage in favour of the high-capacity wagon. It is reported that the use of the new wagons will be considerably extended during the present year.

Factory Legislation.

It is announced that the Home Secretary has definitely made up his mind that it will be impossible to introduce a Factory Bill this session; but appropriate legislation is under consideration, and will be placed before Parliament at a later period. It is stated that the Home Office view is that the factory legislation of the country is already the best in the world, and that for various reasons it would be inopportune at present to introduce a set of entirely fresh proposals. We are inclined to think the job is a bigger one than the Government are, in the present state of public affairs, willing to tackle.

Coal Mines' Inquiry.

The Joint Committee of coal owners and representatives of the Miners' Federation met nearly a fortnight ago, and had a long discussion on the vital questions of output per shift worked and the costs of production. Figures were laid before the Committee as to the cost of production in the English coalfields as compared with the cost in Germany and other Continental and American coalfields. The importance of the English figure approximating to those in competing coalfields was stressed, not only as regards the export trade, but in its effect upon other industries in which coal is a raw material. The Committee will meet again to-day and to-morrow. The representatives of the miners are proposing to criticize the amounts paid to general managers, managers, and secretarial staffs, which suggests that there are likely to be some lively passages.

Miners' Minimum Wages.

The House of Commons last Friday on sound grounds refused to give a second reading to the Bill promoted by the Miners' Federation to fix a minimum wage of 12s. per shift for miners. The House declined to establish a rigid minimum, which would withdraw from those directly concerned the power to settle their own affairs in consultation and conference on conditions prevailing at any given time. The House heard information as to the severe competition that British coal is to-day receiving from foreign produce; and the members also learned that, if the Bill was passed, it would raise the average cost of production by 2s. or 3s. per ton, and in some centres by 4s. and 5s.

PERSONAL.

Two officials of the Burnley Corporation Gas Department, Mr. A. B. Munro (Showroom Manager) and Mr. G. Langstreth (Assistant to the Gas Engineer), are leaving, the former having accepted a position as Sales Superintendent to the Edinburgh Corporation, and the latter going as Deputy Engineer to Todmorden. On Wednesday, March 25, Mr. J. H. Clegg, the Gas Engineer, presented each with a solid silver cigarette case, a pipe, and a pouch.

Mr. John Whitaker, Indoor Superintendent to the Bradford Corporation Gas Department, who retired on March 31 after 48 years' service, was presented on March 26 with a handsome silver cigar box and a cigarette case, the gifts of the members of the Gas Committee. Among those who spoke appreciatively of his work were Mr. George Walker, Chairman of the Gas Committee; Mr. J. H. Barraclough, ex-Chairman; and Mr. Charles Wood, Gas Engineer and General Manager. Mr. Whitaker is succeeded by Mr. J. W. Horwill, the newly-elected Hon. Secretary of the Yorkshire Junior Gas Association.

At a smoking concert in the dining hall of the Gas Light and Coke Company's Chief Office in Horseferry Road, on Tuesday of last week, a presentation was made to Mr. H. Dodimead, Chief Lamp Inspector, who retired on March 31. Mr. F. W. Goodenough (Controller of Gas Sales), in making the presentation, referred to the long and honourable service of nearly 46 years which Mr. Dodimead had rendered to the Company, during 21 years of which he had served under him as Chief Lamp Inspector. He referred to the fact that Mr. Dodimead expected to celebrate his Silver Wedding in the present year, and therefore the gifts that they were asking him to accept were particularly appropriate. They wished him and his wife good health in their retirement, so that they might have a chance of celebrating their Golden Wedding. Mr. Dodimead, in reply, expressed the sincere thanks of his wife and himself for the magnificent gifts. He also wished to thank, on his own behalf, the whole of the public lighting staff for their loyalty and devotion to duty during the years he had been at the head of that department. He could truly say that, thanks to this good service, the street lighting in the Company's district was second to none. The gifts comprised a solid silver coffee service and Wedgwood cups and saucers, from the workmen and staff of the department; a massive silver tray, from the office staff of the Company; a leather suit case, from the Local Managers and Inspectors-in-Charge; and a pair of silver candle-sticks for Mrs. Dodimead, from the workmen and staff.

OBITUARY.

Mr. J. Marshall Thomas, ex-Mayor of Penryn, Cornwall, died last Friday at the age of 75. As Chairman of the Penryn Gas Company, he performed valuable work in the borough.

The death of Mr. T. S. S. Gardner, of Kidderminster, at the age of 77 years, is announced. For many years he served on the Ledbury Urban District Council; and he was a Director of the Ledbury Gas Company, of which he was Secretary for about nine years.

Departure of the Prince for West Africa.

The following telegram was addressed to H.R.H. the Prince of Wales previous to his departure on Saturday last: "Institution of Gas Engineers send you loyal greetings praying that your tour may be as successful in promotion of world's good fellowship as previous tours. Wishing you God-speed. Ferguson Bell, President." A reply was received as follows: "Sincere thanks to the Institution for good wishes. Edward P." The Secretary, Mr. W. T. Dunn, represented the Institution at Victoria Station during the departure of His Royal Highness.

Gas at the Pit's Mouth.—Discussing low-temperature carbonization before the Franklin Institute, Dr. H. C. Porter remarked that proposals are often made, in connection with projected large-scale power development, or central station arrangement for gas, at the coal mines, to utilize some process whereby the coal is gasified completely, with a bye-product of tar and possibly ammonia. Duplex plants are possible, using low-temperature carbonizing retorts together with gas producers or water gas generators, or a single combination process. It is problematical whether such central gas-distributing stations, by the use of cheap coal and the saving of a certain amount of tar oils and ammonia, could thereby secure sufficient advantage to off-set the high cost of the gas-distributing mains and the carbonization plant investment.

HENRY EDWARD JONES.

1843—1925.

The gas industry has suffered a serious loss by the death of Mr. Henry Edward Jones, who passed away at his home, Marden Ash House, Ongar, Essex, on the afternoon of Tuesday, March 24. Mr. Jones had been out riding that morning, and after luncheon had attended to several matters in connection with his Magistracy. He was preparing to go for a walk when he felt unwell; and although medical assistance was quickly forthcoming, he passed peacefully away in the presence of his daughter, Miss Ethel Jones, with whom he conversed to within a few minutes of his death.

Mr. Jones was born in Chester City in April, 1843, and was therefore nearly 82 years of age. He was the second son of Robert Jones, an eminent gas engineer of his time, who moved to Worcester in 1844, Bath 1845, Wolverhampton in 1846, and London in 1853, when appointed Engineer to the Commercial Gas Company.

He was educated at the City of London School and Stepney Grammar School, leaving in December, 1858, after passing with Honours the Cambridge Higher Local Examination. In 1859 he was articled to Joseph Beattie, the Locomotive Engineer of the South-Western Railway, and on the completion of his articles in 1862 commenced his professional career at the Harlow Gas-Works, Essex. After working as a student in Dr. Medlock's laboratory, and gaining practical experience at Pontypridd and Toddington, he was appointed, when 20 years of age, Engineer to the Wandsworth Company in 1863. He held this position until October, 1869, when he was appointed Engineer to the Ratcliff Company; but in the meantime he had paid professional visits in an advisory capacity to the Lisbon and Oporto Gas-Works (1863), Athens (1865), and Spain (1866). He married in April, 1865, and lived at Wandsworth until 1870, when he moved to East London, in order to be closer to his work.

In December, 1875, the Ratcliff Company amalgamated with the Commercial Company, and Mr. Jones was made Joint Engineer with his father. The Poplar Works of that Company were commenced in 1876; and on the retirement of Robert Jones in 1880, his son became Chief Engineer.

In 1902 Mr. Jones retired from the Commercial Company, and was elected to the Board of Directors, and in the meantime had moved to Marden Ash House, Ongar, where he lived until his death. He lost his father in 1896, and his wife in 1901.

During the later years at the Commercial Company, he had built-up a large consulting practice, and was Consulting Engineer to Eastbourne, Watford, Margate, Canterbury, Faversham, Dublin, European, Bombay, Primitiva, Whitstable, Woking, Enfield, Bishop's Stortford, and other Gas Companies too numerous to mention. He was, both before and after his retirement from active management, in great demand in parliamentary matters, rating cases, arbitrations, and such like. His intimate knowledge of the design and construction of works, the practical side of gas manufacturing and purification, and his administrative ability rendered his services as expert witness of immense value.

In September, 1888, he visited Boston (U.S.A.) on professional matters; and he was in personal touch with gas affairs on the Continent, in India, and in South America. He was prominent in the various classic fights relating to such matters as sulphur restrictions, burner Bills, and other legislation promoted to relieve the industry from cumbersome and costly obligations. He was engaged on rating cases for the old East London Water Company, and the Metropolitan Water Board.

Between 1905 and 1910 he gradually relinquished his consulting practice at Palace Chambers, Bridge Street, Westminster, and gave more attention to administration from the Directors' table. At the time of his death he was Chairman of the Wandsworth, Wimbledon, and Epsom District Gas Company, the European Gas Company (owning eight works in the North of France), the Bombay Gas Company, the Uxbridge, Wycombe, and Maidenhead Gas Company, the Primitiva Gas Company of Buenos Aires, and the Loddon Gas Company, and was Deputy-Chairman of the Commercial Company.

Mr. Jones was for many years Chairman of the Gas Companies' Protection Association, and took an active interest in its proceedings. He was one of the prime movers in the formation of the National Gas Council, and was first President. He was included for election this year as an honorary member of that body.

For many years he had been a prominent member of the Institution of Civil Engineers, having been admitted Associate in 1869, and transferred to membership in 1875. He was for a long period a member of the Council, and finally reached, in 1917, what must be the summit of every engineer's ambition—the Presidency of that Institution. Previous to his election to the Council, he had read three papers before the Institution—on the "Construction of Gas-Works" in 1875, "Purification of Gas" in 1880, and "Modern Practice in Manufacture of Gas" in 1900. He received several notable awards from the Institution, among which were the Telford Premium, the Watt Medal, and the George Stephenson Medal.

He was also a member of the Institution of Mechanical Engineers, having been admitted in 1878; and he was connected with the Benevolent Fund of this body. He delivered before the Institution in 1916 the Hawksley Lecture; the subject chosen being "Gas Engineers of the Last Century."

The deceased was, of course, an old and valued member of our own Institution of Gas Engineers, of which he was President in 1903-04; and he contributed from time to time to the proceedings. He presented the London Medal to the Institution, to be awarded annually for the best paper presented on a "subject of practical interest to gas engineers." One of his latest acts before his death was to transfer sufficient stock in one of his Companies to maintain the income for the permanent annual presentation of this medal.

Mr. Jones always took a lively interest in the politics of gas, and was a frequent contributor to the Technical Press on the topics of the day. For many years he was a Governor of the East London College and a Justice of the Peace for the County of Essex. A great outdoor sportsman, his favourite occupations were riding and hunting; and he won many point-to-point races and other events on his own horses—the first, on Knight in April, 1885, when he won the Essex Consolation Cup. The last was in April, 1896, when he won the heavy point-to-point on Colonel; his age at that time being 53 years. He was a great reader, and his library at Marden Ash bears testimony to his interests in country pursuits, local history of various parts of the country, science, and travel.

Two sons pre-deceased him, but he leaves two sons and three daughters. Mr. Frank Jones, M.Inst.C.E., is the well-known gas director and administrator; while Mr. Stanley Jones, M.Inst.C.E., is the Chief Engineer of the Commercial Gas Company, and is on the Directorate of the Oriental, Uxbridge, and Burnham Companies. His three daughters are Mrs. Ransome, Miss Mabel Jones, and Miss Ethel Jones. The last-mentioned lived with him at Ongar.

THE FUNERAL.

Probably in recent years, certainly not since the funeral of Sir George Livesey, have there assembled so many representing the varied interests of the gas industry as were present on Saturday at High Ongar, Essex, when the last solemn rites on the passing of the beloved doyen of the profession were observed. The occasion was a striking demonstration of the high regard and esteem which Mr. Jones had won from numerous friends by his sterling qualities and unquenchable enthusiasm in everything he undertook.

In addition to those associated with him in his life's work as a gas engineer, there were, of course, many others who knew him in his other activities. Notably his friends of the Essex Hunt attended, with their Secretary, to express their feelings of devotion to a staunch member and active supporter of the Hunt for a period of fifty years.

Among those of his engineering colleagues present were Dr. Charles Carpenter, C.B.E., President of the South Metropolitan Gas Company; Mr. J. Ferguson Bell, M.Inst.C.E. (President), Mr. Charles F. Botley, M.Inst.C.E. (Senior Vice-President), and Mr. Walter Dunn, M.I.Mech.E. (Secretary), of the Institution of Gas Engineers, of which Mr. Jones was President in the year 1903; Mr. Thomas Goulden, M.Inst.C.E., of the Gas Light and Coke Company; Mr. A. E. Broadberry, M.Inst.C.E., of the Tottenham District Light, Heat, and Power Company; Mr. Charles Hulme, of the Uxbridge, Maidenhead, Wycombe, and District Gas Company; Mr. Robert B. Anderson, of the Gas Companies' Protection Association; Mr. E. J. Fottrell, of the National Gas Council, of which Mr. Jones became the first President; Mr. Cyril M. Croft, of the Wandsworth, Wimbledon, and Epsom District Gas Company; Mr. Frank Bush, of the South Metropolitan Gas Company; Mr. George Evetts, M.Inst.C.E.; Mr. A. R. Burch, M.Inst.C.E., of the Bombay Gas Company; Mr. Robert Grant, J.P., of the Primitiva Gas Company; Mr. G. M. Gill, M.I.Mech.E.; and Mr. F. W. Cross, M.Inst.C.E.

Lord Lambourne, P.C., Lord Lieutenant of Essex, and Lady Colvin, wife of the former M.P. for West Essex, were present, as also Mr. H. C. Honey, Director of Gas Administration, Board of Trade.

The funeral service took place in St. Mary's Church, High Ongar, and was impressively conducted by the Rector, the Rev. G. R. Nesbitt, M.A., assisted by Canon Reeve, of Standon. The music, which was rendered by the small village choir, was arresting in its simplicity. Boys of the local Wolf Cub Pack with their Cub Master formed a Guard of Honour. The chief

mourners were Mr. Frank H. Jones and Mr. Stanley H. Jones. Numerous beautiful floral tributes were sent, among others by the Institution of Gas Engineers, the National Gas Council, the British Commercial Gas Association, and the Gas Companies' Protection Association.

Simultaneously with the interment at Ongar a memorial service was held at the Savoy Chapel, and was attended by many friends, including Mr. Basil Mott, C.B., Mr. D. Milne Watson, Mr. Charles Hunt, Mr. R. W. Edwards, Mr. Honoratus Lloyd, K.C., Mr. W. J. Smith, and Mr. J. C. Walker.

Henry Edward Jones, born April 26, 1843, died March 24, 1925, has left us poorer by his passing from us; his memory will ever be held in affectionate remembrance.

THE LATE MR. H. E. JONES ON A FAVOURITE MOUNT.

APPRECIATIONS.

Mr. Basil Mott, C.B., President of the Institution of Civil Engineers.

I have learned with deep regret of the death of my old friend, Harry E. Jones, on March 24.

His works as a gas engineer are well known; and during the whole of his long association with this Institution, as a member of Council, and as President in 1917-18, he rendered great service to the profession. It is difficult to exaggerate the loss all members of Council will feel at the death of one whose advice was always most willingly given, and was most helpful.

He was a gentleman and a sportsman in the highest meaning of the words, whose cheerful and kindly friendship endeared him to all who had the privilege of knowing him.

Mr. D. Milne Watson, President of the National Gas Council.

When the news reached us of the death of Mr. Harry Jones, we looked at each other startled, incredulous. It was as if the familiar light of day had become dimmed, a dismal fog of depression had crept up, blotting out the bright sunshine.

We can ill spare him—our dear old friend—the brightness of his nature, the never-failing encouragement of his hopefulness, his humour, his delightful whimsical letters that always brought with them a breath of that wonderful spirit.

Even in his business correspondence, he would urge one on by such expressions as "Tally-ho!" "For'ard on"—borrowed from his favourite sport. He hunted almost to the end, and was riding on the day of his death. And he was 82 years old! To how many of us is given that power of keeping the boy in us alive under the weight

of years, the benumbing influence of disappointments, disillusions, and *atra cura?* He brought to the industry in his forceful personality that fearless truthfulness which, though as he himself expressed it, sometimes led him into "blazing indiscretions," yet inspired all who had the privilege of his friendship with the spirit of enthusiasm that he shed around him, and made the hardest and most monotonous efforts emphatically worth while.

We can only show our appreciation of his character by keeping alive that spirit, hard as it will be without his brave heart to rely on, or his hand to grasp.

Dr. Charles Carpenter, C.B.E., M.Inst.C.E.

The death of Mr. Harry Jones robs the gas industry of its outstanding personality—I had, indeed, almost added, and of the last gas-maker. He was articled in the locomotive shops of one of the great railway companies, and there laid the foundation of that sound engineering knowledge which served him in good stead throughout his professional career. In those days, too, there were master locomotive-builders busily thrashing out the details of rolling stock construction from "Flying Dutchmen" to coal wagons; fighting the battles of crank *v.* straight axles, and so inside *v.* outside cylinders; iron or copper fireboxes; chain, air, or vacuum brakes, not forgetting the gauges—burning problems in those days, and needing all the inventive genius of the technician to furnish solutions, while maintaining all the while the safety of the travelling public. To-day locomotives are built all over the world and by all nations on lines which are well understood and in which improvements are made in detail rather than in principle. The master locomotive-builder is no more—his day has passed. In the same sense Harry Jones must be numbered among the master gas-makers of an era which, too, will not return. Who to-day remembers the controversies centering round such questions as ground floor *v.* stage retort house; cast *v.* rolled girders; dips *v.* anti-dips; faced *v.* luted lids; dry *v.* wet purification? The principles concerned in gas manufacture are to-day well understood, and the engineer has the knowledge of them at his fingers' ends; he has not to seek it in the dim labyrinths of the unknown. Let us give as an example an episode in the life of a gas engineer of those days. It is Sunday and he and his wife are starting out for church—one perchance of the many the great Sir Christopher built for our London forefathers, and which they were wont to attend with little-failing regularity. "I must have a look at that troublesome hydraulic, my dear. You go on; I will soon catch you up." From standing at the retort-house door talking to his foreman, the engineer is little by little drawn inside, and soon proceeds to elaborate his investigations by climbing on the "beds" in his silk hat and Sunday clothes. Then taking off his coat, he turns up his white linen shirt sleeves, and thrusts his arm through the manhole into the hydraulic main, getting very tar-stained in the process. To-day it is known why mains and arch-pipes may become blocked with pitch and carbon, but the engineer of Harry Jones' day had to learn these things for himself, and dig out the underlying causes. A differently constituted London from the present lived and worked in those days when only the well-to-do had the luxury of a gas supply, and gas cookers were practically unknown. The engineer's great domain was then his works, and the chief inspector kept in order the district up to the consumers' meters, beyond which not a finger was lifted to help.

Our friend was but a young man when he left Wandsworth to join the Ratcliffe Company, which had a separate existence on the banks of the Thames at Wapping, near by which ran the famous "Highway," with a gasholder station somewhere about Shadwell alongside the railway to Blackwall—a line worked first by rope haulage and later by steam, though in its passage through dockland its track had to be roofed-over to protect the neighbouring goods from engine sparks. It is just fifty years now since the Ratcliffe Company was absorbed by the Commercial Gas Company, which then became the first London sliding-scale gas undertaking; and Harry Jones was appointed Engineer of the joint concern. I think this fusion constituted the tide in his affairs which led to Fortune. The application for the first time, at any rate in the Metropolis, of the germ of the principle that business profits should depend upon business skill, even in the management of a gas undertaking, undoubtedly provided the turning-point in his career; and to the golden rules until then in force were added "Keep down your capital expenditure," and "Keep low the price of gas." The influence of this new attitude upon works construction was far-reaching, for the advocate of economical construction of new plant, and of the intelligent use of old plant, carried these principles not only to the Commercial Works, but far and wide in the extensive general practice he built up as a Consulting Engineer. Of his many contributions to technical literature, I would single out for special notice "Jones on the 'Purification of Gas'" and "The Illuminating Power of the Gas of the Future." The latter constituted one of the early forecasts of the future development of gas supply made possible by the extended use of the bunsen flame for incandescent gas lighting, and for cooking and heating appliances. The former won him a Watt Medal and a Telford Premium given by the Institution of Civil Engineers, of which body he was in later years elected to the Council, becoming President in 1917. His action in this latter episode was characteristic of the man. It was the duty of another member to take the chair in the troublous times then prevailing. But his health failed, and Harry Jones, with customary good nature, though his own business had become increasingly arduous, undertook the responsibilities of the presidency. It can be truly stated that no President enjoyed more fully the respect and affection of all his colleagues than he did. His constant thought was directed to maintaining unimpaired the high traditions of the Institution; and he always looked with a jealous eye upon any proposals to associate too intimately therewith the constructing element as distinct from the designing branch of civil engineering.

But Harry Jones was something more than a good engineer. He was an all-round man of the world who took unceasing pleasure in associating with his fellow men in all walks of life. His hunting proclivities are well known to all. "Jumping Jones" was for many a year his soubriquet in his county. He enjoyed steeplechasing, as to which he told at least one amusing story. He delighted in polo also; and while he may not have been the smartest player of the team, he was generally the most reliable, for although he was one of the best judges of a bottle of wine that I have met, he was abstemious in the highest degree, and was therefore always "fit" when his associates were sometimes a little "off colour."

When he was considering having his portrait painted, I urged him to sit to Orpen. The conversations of the artistic Dubliner would have helped to get those rugged features on the canvas toned to humour by reminiscences of horse shows and Punchestown. Failing this, I suggested Mullings, for the only characteristic likeness I have seen of him is a snapshot of himself on a favourite horse, when he looks his best. The Institution portrait is, in my opinion, like most of its companions, a poor counterfeit of the real personage it purports to present.

I have said Harry Jones was an all-round man. He was; and therein lay his charm and the secret of his success. He was as much at home with a peer as with a policeman, a countess or a songstress, and he had the right word to say to each. One of my pleasant recollections is of him standing in a doorway in Rennes to catch a glimpse of the "divine Sarah," then on one of her last journeys to Belle-Ile-en-Mer. I think his happiest holidays, of later years at any rate, were spent in France, in which country he was ever ready to find delight in her cathedrals, her chateaux, her galleries, and with her people. Had he belonged to that country he would long ago have been enrolled in her Legion of Honour. Being British, and neither a self-seeking politician nor a greedy profiteer, he died as he lived, plain Harry Jones. After all, "Kind hearts are more than coronets," as Robertson told us long ago; and to those who knew him best his was kindly and genial to the full. He was by nature deeply loving and affectionate; and despite his great age, his death will leave a gap, not easily filled, in many places. That the people of Ongar were among those who loved him, was shown by the drawn blinds throughout the village on the funeral afternoon. But even yet more impressive

was the absolute stillness and silence in the church as the Vicar read the chosen chapter from St. Paul's Epistles—almost as though all hearts present were beating quietly lest they should disturb that of their brother so lately stopped. I shall miss Harry Jones; who among us will not?

Mr. J. Ferguson Bell, M.Inst.C.E., President of the Institution of Gas Engineers.

By the unexpected death of Mr. H. E. Jones, M.Inst.C.E., M.Inst.Mech.E., the gas profession has lost one of its most striking personalities. His long and distinguished career as an eminent engineer, accomplished administrator, and wise adviser, won for him an outstanding position in the gas world. He was held in high esteem by those more immediately connected with him, and justly recognized as an authority on the science and practice of the gas industry, and especially executive control—being a Director of several well-known companies. To his discernment and wise guidance, the Commercial and Wandsworth Gas Companies owe much of their success.

It was the intention of the Institution of Gas Engineers, of which he was President in 1903, to recognize, at the annual meeting to be held in June, his conspicuous services extending over many years, by electing him an honorary member. Alas! this was not to be. Instead, death removed one on whom years appeared to sit lightly—the doyen of the gas profession—to the profound sorrow of his many friends, as was manifest by the large and representative gathering at High Ongar Church last Saturday, to pay their last tribute of respect.

Mr. H. E. Jones was never afraid to express forcibly his views; and the active interest in the work of the gas industry was maintained in full vigour until the day of his death. He passed peacefully away at the end of his 82nd year—honoured for his untiring work on behalf of the industry which he had so much at heart.

He recognized the importance of progress; and to stimulate the activities of members to contribute to the transactions of the Institution, he recently provided sufficient funds for the award annually of the London Gold Medal for the best paper presented dealing with some subject of technical interest, and which will in future be known as the "H. E. Jones, London Gold Medal."

He was first Chairman of the National Gas Council and for many years Chairman of the Gas Companies' Protection Association, and Justice of the Peace for the County of Essex for over 50 years. He will assuredly be greatly missed.

Condolences are assured to his two sons (who happily are following with much success the profession of which their father was an honoured member) and three daughters. A happy background to a long and eventful life was his ceaseless devotion and affectionate regard for his family, fortunately still a characteristic of most famous men.

The Ravine Seam of the Lancashire Coalfield.

The survey papers of the Fuel Research Board form a series of papers on matters connected with the physical and chemical survey of the coal seams of Great Britain. Report No. 4 (published by H.M. Stationery Office, Adastral House, Kingsway, W.C. 2, price 1s. 6d. net) describes laboratory experiments carried out by the Lancashire and Cheshire Coal Research Association on the Ravine seam of the Lancashire Coalfield, which is recognized over a large area, but has been worked only to a limited extent. The reasons for this are that the seam varies greatly in composition, and frequently becomes much split-up by dirt partings and bands of shale; also it shows marked tendencies to undergo spontaneous ignition in the goaf. It is a bituminous, caking coal, and is employed for gas-making, manufacturing, and household purposes. In certain areas, the ash and sulphur contents—especially the latter—are high for too easy utilization for gas manufacture. The composition and melting-point of the ash from different horizons in the seam may differ considerably. The ankerites in the Ravine seam undergo oxidation much more rapidly than is found to be the case in other seams examined. A series of tests showed that the coal could be greatly purified by washing. The fact that the seam is so variable in composition suggests that its utilization in the form of pulverized fuel may be of considerable importance.

ELECTRICITY SUPPLY MEMORANDA.

There seems to be some misconception on the part of at any rate the Hastings Corporation, if not other municipal authorities, as to the powers of the Electricity Commissioners to deal with national funds, or to make promises in regard to subsidies from them to maintain non-paying electricity schemes. Whatever the late Labour-Socialist Government may have committed themselves to in respect of subsidies has no binding effect upon the new Government. The present Government would not interfere with what their predecessors actually consummated, unless imperatively necessary in the national interests; but they cannot be bound to go farther with schemes in respect of subsidizing unless such commend themselves to them. Recently reference was made in the "Memoranda" to the fact that the Hastings Corporation were proposing to carry out a scheme of supply to outer villages and districts at a large cost. An estimate by the Electrical Engineer has shown that, if business develops in the outer areas as luxuriantly as he devoutly hopes it will, there will be a deficit of £1100 on the first year's working. The "if" is important. Electrical balance-sheet estimates often go astray—in the wrong direction; and we see nothing in the report of the Electrical Engineer in the way of a guarantee that the business he expects will be obtained, or that the calculated deficit will not be much more. It is all peculiarly vague; and it is on this that the Hastings ratepayers are asked through their councillors—be they wise or foolish—to shoulder a heavy expenditure. The ratepayers should look very closely into the matter. But there has been some attempt to placate any fears that may arise by telling them that any deficit will be made good out of the bountiful National Exchequer! In fact, in a note in a local paper, it was stated that there was a "definite understanding" that this would be so. Now does any sane man believe that the present Government would commit the taxpayers to an obligation to wipe-out all deficits that may arise, whatever their extent, in concerns over which the Government have no immediate administrative control? Mr. C. F. Botley, the Engineer and General Manager of the Hastings and St. Leonards Gas Company, wrote to the local paper pointing out that there could be no "definite understanding" of the kind, in view of the fact that the Government are still investigating the question, and have not yet determined upon any settled policy.

Electricity and National Money.

Mr. Botley is right; and we say this despite the assurance of the Town Clerk to the writer of the note in the local paper which gave publicity to the "definite understanding" hypothesis. A careful reading of what the Town Clerk had to say distinctly supports Mr. Botley's assertion. The Town Clerk is himself indefinite and vague on the subject. In the first place, he says it is not correct for Mr. Botley to say there can be no "definite understanding" as to any deficit. "There is," the Town Clerk adds, "a definite understanding between the Electricity Commissioners and the undertakers of electricity supplies in this country." The Town Clerk refers to a conference held last October, at which "it was stated that, with a view to the encouragement and development of electricity in rural areas, the Commissioners were prepared to make grants which would cover the loss of the undertakers on such rural schemes." The Electricity Commissioners have no power to vote the taxpayers' money away in this manner. They can only recommend. The Ministry of Transport and finally the Government stand between them and the parting with national money to make good deficits on the speculations of an industry run by local authorities and private enterprise. And October, 1924, is not March, 1925. We are rather surprised at the Town Clerk defending the "definite understanding" submission on such obviously shallow grounds. But he himself proceeds to show the insecurity of the "definite understanding" theory, and so supports Mr. Botley's contention that it cannot exist in a form to be "definite," or to have any reality, when he states that the new Government have been approached, and their reply was that their policy on the point has not yet been formulated. This being so, it would be interesting to have from the Town Clerk a positive interpretation of "definite understanding," and an indication of how it is he thinks the Electricity Commissioners have power to pledge the paying of money to liquidate losses on electricity speculation. If electricity, why not coal, gas, oil, water, and other things? There must be no preferential treatment by subsidizing any commodity (particularly a competitive one) in this country. We think that Hastings and its local officials should get from the present Government themselves a "definite" undertaking as to what they are prepared to do in the matter of wiping-off deficits on electricity speculation before making use of such a nebulous understanding as the one to which attention is here directed. We are strongly opposed to the subsidizing of indus-

The Indefinite Understanding.

tries by the Government; but if it is to be done in one industry, it should be applied to others.

Circulating Falsehood.

Give a lie a good start, and it is difficult to overtake it, unless those who do the circulation have sufficient good manners to acknowledge it when they know the truth. "Meteor" in the "Electrical Times" thinks he has found a nice tit-bit regarding the lighting of the offices of the Gas Department at the City Chambers of Glasgow; and he has been making energetic use of it. This is an example:

> Gas, says Mr. Goodenough, provides ventilation. That should be explained to the Glasgow Municipal Gas Department who complain so bitterly of bad air that a recommendation has been made to replace gas lights by electric throughout the municipal gas offices.

The best way to show how false is the statement that the Municipal Gas Department have "complained bitterly," and that it is through this a recommendation has been made to replace the gas lighting by electric lighting, is to give a history of the matter, which refers to the Surveyor's Section of the Department. Going back to the time when the section was housed on the first floor of the old City Chambers (up to June, 1923), the room was lit by electricity, and the ventilation provided (but not used) was similar to the system in the new City Chambers—*i.e.*, forced air currents actuated by fans in the turrets. The atmospheric conditions there (with electric light in use) were extremely unpleasant, arising from the smell of damp and drying clothing of men and stagnant air. The atmosphere was foul; and that was with electric light in use. In answer to appeals, information was given that it was impossible to use the fans provided because of complaints from the City Assessor that they caused a draught in his Department. Knowing that the Gas Department were to vacate the room within two years, the staff were asked to bear the conditions as best they could. In order to secure better arrangements in the new building, the architects were invited to pay particular attention to the matter. Assurance was given that the fans would be worked regularly, and that precautions had been taken to avoid inconvenience to the City Assessor's Department, which was to occupy rooms above the Gas Department in the new building as they did in the old one. For a considerable time after occupying the new premises, the fans were worked regularly, and the conditions were pleasant and in marked contrast to the old. Subsequently the fans were stopped; and there was again trouble. The result was that the General Manager of the Gas Department (Mr. John W. M'Lusky) wrote to the Town Clerk as to the inadequate ventilation of the survey room and the complaints counter in the Department. In his letter, he remarked: In the survey room from four o'clock onwards, there are upwards of 250 men employed, and the ventilation is most inadequate. We understand that this is on account of the fact that the fans are not in use, and we shall be glad if your Committee will give instructions that the fans be regularly in operation.

The Present Position.

The Municipal Buildings Committee remitted the matter to a Special Sub-Committee, to whom it was explained that the Gas Department had no complaint to make so long as the fans were running. But when 250 men came into the survey rooms (sometimes with wet clothing) the atmosphere became foul; and although the current of air provided by the heat from the gas lighting helped to some extent to clear the air, it was not designed to ventilate the room completely. The Sub-Committee subsequently recommended the removal of the gas-fittings in the Gas Department, and ignored the request that the means of ventilation provided at considerable cost should be used. The Department have submitted that, should this decision be ratified by the Corporation, it would not remove the cause for complaint, as it is not the products of gas combustion which are the cause (they naturally rise and find their way to the ducts provided at roof level), but it is the smell of the natural human excretions from lungs, skin, and clothing in a damp condition. Moreover, the Corporation, by ratification of such a proposal would give approval to the suggestion that gas lighting pollutes the atmosphere of buildings, which is entirely opposed to fact. It must also be remembered that quite 50 p.ct. of the business of the Glagow Corporation Gas Department depends upon gas lighting; and it would be damaging to have such a suggestion broadcast as the considered opinion and policy of the Corporation. The Department feel sure the Council will not deliberately be a party to such a suggestion. This history of the matter puts on it quite a different complexion from the one which "Meteor" of the "Electrical Times" has been so sedulously circulating.

EVENING STAR LODGE, No. 1719.

Installation Meeting.

The Installation Meeting of the Evening Star Lodge, No. 1719, was held in the Grand Temple of Freemasons' Hall on Wednesday last, the retiring W.M., W. Bro. Rae P. Normand, presiding at the commencement of the proceedings. There was an exceptionally numerous attendance of members and visiting brethren.

After the usual preliminary business had been transacted, the installation of W. Bro. Hermann L. Sheppard was carried out; W. Bro. Normand acting as Installing Master.

The installation of W. Bro. E. G. Smithard, P.M., P.P.G. Treas. (Norfolk), who had been duly elected as Treasurer, was deferred to a subsequent meeting on account of his absence through illness. The other officers were appointed and installed as follows:

W. Bro. Rae P. Normand	I.P.M.
Bro. Alfred H. Henry	S.W.
Bro. Fredk. G. Cockey	J.W.
W. Bro. H. W. Packham, P.M., P.P.G.D. (Surrey)	Chaplain.
W. Bro. Walter T. Dunn, P.M., L.R.	Secretary.
W. Bro. Frank West, P.M.	D.C.
W. Bro. A. L. Croager	S.D.
W. Bro. James W. Foreman	J.D.
Bro. John F. Simmance	Organist.
Bro. John A. Brentnall	I.G.
W. Bro. Reg. W. Foster, L.R.	Steward.
Bro. Albert B. Potterton	,,
Bro. Thomas F. C. Potterton	,,
W. Bro. R. H. Goddard	Tyler.

W. Bro. Thomas Cash, P.M., L.R., was elected an Honorary Member of the Lodge, on the nomination of the Standing Committee, in appreciation of his long and distinguished services to the Lodge and freemasonry generally. In returning thanks, W. Bro. Cash referred in feeling terms to several of the old members with whom he had been associated in the early days of the Lodge.

Bro. E. H. Swain, Engineer to the Metropolitan Gas Referees, was elected a Joining Member; and the following were proposed for initiation: Mr. Wilfred Baker Claridge, Engineer to the Marlborough Gas Company; Mr. James Waldron Swan, Assistant Manager and Secretary to the Hitchin Gas Company; and Mr. Leslie W. Dunn, Assistant Engineer on reconstruction of gas plant at the works of the Liverpool Gas Company.

At the dinner which followed, in the Connaught Rooms adjoining, W. Bro. Sheppard presided.

The toast of "The Worshipful Master," which was proposed in adequate terms by W. Bro. Normand, was responded to by W. Bro. Sheppard, who in turn submitted that of "The Installing Master," W. Bro. Normand.

W. Bro. Arthur Valon, P.M., L.R., gave the toast of "The Visiting Brethren" in an extremely interesting speech. It was responded to by W. Bro. James Bridge, W.M. of the Northern Star Lodge; W. Bro. Vale, S.W. of the Murdoch Lodge; W. Bro. John Ineson, of the Yarborough Lodge; and Bro. Leslie Rae.

The health of "The Past Masters and Officers of the Lodge" was appreciatively proposed by the W.M. W. Bro. Arthur E. Croager, P.M., replied for the former and Bro. Alfred H. Henry for the latter.

An excellent musical programme was provided, the numbers of which were interspersed with the toasts.

Emergency Meeting in June.

As in previous years, arrangements have been made by the Evening Star Lodge to enable those members of the Institution of Gas Engineers who are masons to meet some of their brethren in masonry in connection with the annual meeting of the Institution. The W.M. (W. Bro. Rae P. Normand), the M.E. (Bro. Hermann L. Sheppard), Wardens, and Brethren desire to invite all members of the Institution who are freemasons to attend. The Emergency Meeting for the purpose will take place on Monday, June 8, at 5.30 p.m., in the Grand Temple of Freemasons' Hall, Great Queen Street, W.C. After the Lodge, the brethren would be glad if their visitors would join them at dinner in the Grand Hall of the adjoining Connaught Rooms.

Cutting-off the Sunlight.—Executive heads of the American gas industry are, it is gathered from the "Intercolonial Gas Journal of Canada," waging warfare against the smoke nuisance. They say that an average person consumes about 6 lbs. of food and water a day. In addition to this, he takes into his lungs 32 lbs. of air each day. Vast sums of money are spent to insure unpolluted water and a pure food supply, it is argued, but up to this time little attention has been paid to a pure air supply. Yet every day we use 32 lbs. of air, against a total of 6 lbs. of food and water. The medical profession seems to be agreed that all pollution from soft coal smoke is responsible for many of the diseases they are trying to combat. The influence is both direct and indirect. Possibly the worst is the indirect effect of partially cutting-off the sunlight. This not only lowers the body's resistance, but has a depressing effect on an individual's outlook on life.

SOUTHERN ASSOCIATION OF GAS ENGINEERS AND MANAGERS.

ANNUAL GENERAL MEETING.

The Annual General Meeting of the Association was held on Tuesday of last week, at the Hotel Cecil, Strand, W.C., under the Presidency of Mr. Philip G. G. Moon, F.C.S. (Engineer and General Manager of the Bournemouth Gas and Water Company), who delivered his address. There were other items of interest on the agenda ; and previous to the meeting luncheon was served.

LUNCHEON.

The luncheon room was crowded, and those present included a number of distinguished guests. In addition to his Chairman (Mr. William Cash, F.C.A.), the President was supported by the following Directors of the Bournemouth Gas and Water Company: Sir Charles L. Morgan, C.B.E., M.Inst.C.E. (Deputy-Chairman), Sir Charles J. Jessel, Bart., and Lieut.-Col. Harold W. Woodall, C.I.E., M.Inst.C.E., together with the Secretary (Mr. Herbert A. Plumb, F.C.A.). There were also present the Vice-President of the Association (Mr. R. Robertson, of Bristol), the immediate Past-President (Mr. L. J. Langford, of Tunbridge Wells), Sir Arthur Duckham, Dr. T. Lewis Bailey (Chief Inspector of Alkali Works), and Mr. F. Napier Sutton. The Institution of Gas Engineers were represented by Mr. Walter Dunn, the British Commercial Gas Association by Mr. J. C. Walker, and the Gas Companies' Protection Association by Mr. F. E. Cooper. Mr. J. Ferguson Bell (the President of the Institution of Gas Engineers) was unfortunately unable to attend.

After the honouring of the Loyal Toast,

Mr. R. Robertson proposed "Our Visitors;" remarking that they were fortunate in having with them that day guests who had rendered, were rendering, and he hoped would long continue to render, excellent service to the community, and particularly to the gas industry. Looking through the list which the Hon. Secretary had handed to him, he saw chief among them Mr. William Cash and Sir Charles Morgan (Chairman and Deputy-Chairman respectively of the Bournemouth Gas and Water Company), and also Sir Charles Jessel and Lieut.-Col. Woodall, their co-Directors. Whether or not Bournemouth had adopted a standard of qualification for Directors, it was evident that they had ways and means of securing Directors of the very highest class. In Mr. Cash they had a gentleman who was regarded as one of the foremost gas administrators and financial experts. In addition to being a Past-President of the Institute of Chartered Accountants, he had a very wide business connection with the gas industry. Like all other busy men, he was the very one who was always ready to help others; and he had given ungrudgingly of his time and his vast knowledge and experience, for the benefit of the gas industry generally. They all looked upon him as one of their most valuable assets. The other Directors were also men of wide experience in business and professional affairs, and men possessing reputations that they all envied. Sir Charles Morgan was the immediate Past-President of that most exclusive and aristocratic body, the Institution of Civil Engineers. Lieut.-Col. Woodall was a very old friend of the Association, and they were delighted to see him present that day as an honoured guest. It fell to the lot of few men, as it had done to him, to secure distinction in both military and civil life—and to have a retort called after him. It was a privilege to be able to count him among their honorary members. Among the other guests, they had with them Dr. Lewis Bailey, the Chief Alkali Inspector. They were proud to have him as their guest, and to give him an opportunity of studying the gas manager in more congenial circumstances than was sometimes the case. There was also Mr. Walter Dunn, the kindly and respected Secretary of the parent Institution, and others he would like to mention, but the time was passing.

Mr. William Cash said that, though he felt his responsibility, it was a very great pleasure to be allowed to respond to the toast that had been so kindly proposed by the Vice-President. He would, in the first place, on behalf of himself, his co-Directors, and the other guests, like to thank the Association very much for having invited them to be there that day, and for the cordial reception of the toast. From what had been said, they would have gathered that, so far as the Directors of the Bournemouth Company were concerned, he was extremely fortunate in having with him a Board each member of which possessed special qualifications for administering such an undertaking. He would like to say how much the Directors appreciated the fact that the new President of the Association was their own Engineer, Mr. Moon. For Mr. Moon the Board felt the greatest admiration. They knew that the work he did for the Company was of the very highest character, and therefore that the Association had bestowed upon him a well-merited honour. As to the other guests, though sometimes the Chief Alkali Inspector might appear rather more of a "spectre" than an "inspector," he was very glad that Dr. Lewis Bailey had come along that day to meet gas engineers amid such pleasant surroundings. Then they had also with them Sir Arthur Duckham, who had had a very early association with Bournemouth. He had since gone a long way from it in many directions—especially in the work he did during the war, for which honour had been justly conferred upon him. He thought all company Chairmen would wish to express the debt they owed to the engineers and managers, who really carried on the work of the undertakings. From his own experience, he could bear testimony to the excellent service which these gentlemen rendered—to the advantage of the community and of the investors who put money into gas and water undertakings. Sometimes Boards called upon their officers to assist them, and at others they had to do, as Directors, what their officers told them to do. Sometimes "the boot was on the other leg," and Directors had to undertake duties which their officers ought to perform. That afternoon Mr. Moon really ought to have been at Westminster giving evidence which he was much more qualified to give than he (Mr. Cash) was.

AN INVITATION TO BOURNEMOUTH.

His association with the Bournemouth Company went back to 1891, when he was appointed Secretary. Subsequently he became a Director, and later on Chairman—a position which he greatly valued. He could therefore speak with some knowledge of the undertaking, which had developed tremendously under the management of Lieut.-Col. Woodall, and then of Mr. Moon. Of course, they were fortunate in supplying a town possessing such great advantages as Bournemouth could boast of; but even allowing for this, the increase in output of gas was remarkable. His reason for referring to this growth of business was that Mr. Moon was now engaged on the erection of a complete new gas-works of considerable capacity. The Company were spending something like £300,000; and following a practice of the Association in previous years, it was his pleasure to ask them to visit Bournemouth on some convenient date in May. The Company would be glad of an opportunity of showing them what was going on there, and more particularly what Mr. Moon was doing in the way of providing these new works. He extended to them a cordial invitation. [Applause.] Plans were also out for new showrooms and offices, though he did not think they would be erected by that time. The works, however, would be very well advanced, so as to reveal the plans Mr. Moon had drawn up and carried out—which reflected the greatest credit on him. They would see a works excellently well designed—not too ornamental, and at the same time not too obtrusively commercial—and largely built of reinforced concrete. If there was anything to be learned there, it would be at the disposal of the members.

POSITION OF ELECTRICITY.

Touching for a moment upon electricity, it would, of course, be known to them that they had been dealing at Westminster with the electricity supply of London, and it was interesting to note that the scheme put forward by the London County Council, and agreed to by the Electricity Companies, which had been the subject of discussion that week and in the preceding week before a Parliamentary Committee, brought into operation for the first time in the case of electricity the sliding-scale system with which they were so well acquainted in the gas world. A good deal had been seen in the Press on the subject of subsidizing electricity. So far as the gas industry was concerned, it did not ask for anything, provided it was treated on the same basis as its competitors. Sir Charles Morgan had handed him an extract from a speech by Mr. Woodhouse (the President of the Institution of Electrical Engineers), which put the position very fairly:

> "It would, in my view, be unsound to develop undertakings beyond the economic limit, either by penalizing existing consumers or by State aid, in that alternative services exist for most needs—*e.g.*, lighting by gas; power by self-contained plants, such as the petrol engine, the oil engine, and the steam turbine; heat by gas or coal; and so on."

If the gas industry was treated on these lines, there would be nothing to complain of.

The President thanked Mr. Cash on behalf of the Association for the invitation to visit Bournemouth, and for the kind remarks made concerning him (Mr. Moon). All he could say was that it would be a very poor engineer and general manager who could not be happy and make good under the admirable conditions existing at Bournemouth, and with such a Board of Directors as he had the honour to serve.

The Chief Alkali Inspector.

Dr. T. Lewis Bailey, proposing "The Southern Association of Gas Engineers and Managers," said that gas engineers and managers he knew pretty well, but he had no special name for them. For himself, he had been called all sorts of funny things, and now he was termed a "spectre." Now, spectres had peculiar properties, but they were properties which he was not aware that he possessed. [Laughter.] He had had dealings with gas engineers and managers in all parts of the country—with their President and with their Vice-President—and those dealings had always been of the most satisfactory kind; their relationships had invariably been of the pleasantest. The Alkali Inspectors, as Civil Servants, had never desired to be hard on gas managers, and he hoped never would desire to be hard on them. Whatever they had wanted to be done, had been done in exactly the spirit that they wished—not at all from the point of view of compulsion, but from the point of view of two people working together. One did not like to go about insisting upon points of law; it was far preferable to work from the point of common-sense. Consequently one was always quite willing to discuss—and even to go further than discuss—questions which were not mere points of law. Thus it did happen that in many directions gas managers had worked with his Department to a very considerable extent. The gas managers had done a great deal for his Department, and in return

the Department had tried to do something for them. ["Hear, hear."] The members of that Association, he knew, were not men who simply did a job as a job. They took their work from the right point of view—not doing their business mechanically, but from the highest motives, seeking to make improvement where improvement was possible. Consequently they were always up against all sorts of problems, which they tackled with excellent results. The gas industry of to-day was not the gas industry of even ten years ago; it was a new thing altogether. There was a time when he thought he knew something about gas making; then there came a time when he though, he knew nothing about it.

NEW METHODS ON OLD METHODS.

Perhaps he might be permitted for a moment to refer to the question of dealing with effluents from sulphate of ammonia plants. This was a very big subject. It was practically simple until they got into touch with some of the more modern works. Then he discovered that he had to go back and learn gas-making again; and during the past few years he had been endeavouring to learn something of the modern methods of manufacturing coal gas. He must confess that it had been quite profitable; but it had led him to one conclusion, and he hoped they would forgive him for saying it. It had led him to the conclusion that gas engineers had been going ahead as fast as they could on altered and improved methods of making gas; but he was rather inclined to think that they had stuck there. They had stuck their new methods of making gas on to their old methods of cleaning it; but was this right? It was a suggestion he threw out; and he thought he was right in doing so. Was there not a vast field to be explored in the cleaning of the gas—that was, in the treatment of the gas after it came from the retorts, and before it left the works? Trouble had been experienced in many works in regard to the disposal of the ammonia effluents; and those ammonia effluents at the present day were much worse than they used to be. The point to make was this: Was it better to make a dirty material and clean it; or was it better not to make a dirty material, and then not to have to clean it? He imagined from what he had seen of late that it was possible to make a cleaner liquor, and so prevent any troubles which some of them might be up against. He threw out this suggestion for what it might be worth.

THE ASSOCIATION'S JUBILEE YEAR.

The President, responding, first thanked Dr. Bailey for his remarks, and those present for the cordial way in which they had received the toast. If every Government Department functioned in the way that the Alkali Department did, it would be a much happier country than was the case at present. [Applause.] He was sorry to disagree with his Chairman, but probably he only referred to a "spectre" by way of a joke. At any rate, he could assure him that the inspectors were by no means spectres to those who had charge of gas-works. The Alkali Inspectors were always most helpful, and cordially co-operated with the gas engineers in any of their difficulties—assisting them to overcome those difficulties, and so, by mutual work, to fulfil the letter of the law, which, of course, must be obeyed. As an Association they had this year attained the honourable and dignified age of fifty years, so that it was their jubilee year; and he thought he could claim that every one of these years had been a year of growth and of ripening experience. They had seen the gas industry grow in importance until now it ranked as one of the great public services of the country, which had done much to improve the amenities of life. The widespread use of gas for cooking, heating, lighting, and power had improved out of all recognition the atmospheric conditions of the towns, and had eased the labours of hundreds of thousands of harassed and over-worked housewives. The Legislature had wisely, but perhaps too vigorously, restricted their profits up to the point that no possible charge of profiteering could be brought against the industry; and this, coupled with the economies resulting from the improved methods which such Associations as theirs fostered and encouraged, had led to their being able to offer a very cheap, and therefore very popular, commodity. All this had resulted in the success of the industry being based upon sure foundations; and he did not think it was an industry which, under present conditions, was likely to be easily overturned, in spite of insidious dangers. He could not help feeling that too many of the leaders of the country at the present time, under the hypnotic influence of that potent phrase "super-electricity schemes," were seeing pictures of a new heaven and a new earth which had no foundation in actual fact. Super-electricity schemes would perhaps improve the efficiency of the generating stations from its average of possibly 8 p.ct. now to the 20 p.ct. the optimists claimed; but while this was good in itself, and while electricity had an increasingly important part to play in the country's welfare and development, he did suggest that this increase in efficiency was not enough to warrant all the exaggerated claims that were put forward for it by the people who were promoting these super-electricity schemes, that they were going to revive the industries of the country and put them on a successful basis. At any rate, he thought a very important duty devolved upon every one of the members of the Association, and of the industry up and down the country, to put before the public generally the fundamental facts of electricity generation and gas production, so as to show clearly the relative importance of the two industries in the country's fuel balance-sheet, and that no State aid should be provided for electricity. He repeated that the Association had a definite duty to inform the public of the true facts of the matter. Then they had also another duty—to see that, so far as they were concerned, their own industry was brought up to the highest state of efficiency. They must, if possible, get more per ton from their gas-making operations, and save anything that at the moment might be going to waste, until no higher point could be attained.

THE BUSINESS MEETING.

An adjournment was then made to another room, where the business meeting was held, with Mr. Philip G. G. Moon in the chair.

CONFIRMATION OF MINUTES.

On the proposition of the President, the minutes of the last meeting, as published in the "Journal," were taken as read, and confirmed.

ANNUAL REPORT.

The report for 1924, as circulated among the members, was also taken as read and adopted, on the motion of the President, seconded by Mr. Samuel Glover.

The report included the following items:

The General Committee, in presenting their report for 1924, feel that the period under review has been one of considerable success and importance. The continued growth of the Association and the excellence of the various papers submitted is most gratifying.

The Committee deeply regret having to record the death of the following members: Mr. Henry Morley, Teignmouth; Mr. W. D. Hunter, Rotherhithe; Mr. A. F. Phillips, Westminster; Mr. S. Temblett, Andover; and Mr. C. F. Franks, South Metropolitan Gas Company.

The total number of members is now 304, as compared with 291 at the end of 1923.

The audited accounts show that the receipts during the year were £305 18s., while the expenditure amounted to £287 18s. 10½d.—a credit balance of £17 19s. 1½d. remaining. The total funds of the Association on Dec. 31, 1924, were £75 17s. 1d.

FIFTH ANNUAL REPORT OF THE COMMITTEE OF THE EASTERN DISTRICT.

During the 1924 session, eight monthly meetings were held in London and one county meeting at Guildford. The average attendance of members at the meetings held in London was 28, and at the county meeting 34. Two joint meetings with the members of the Western Section of the Association were held—at Tunbridge Wells in May, and at Portsmouth in October. In each case the attendance of members exceeded the average; and much useful information was gathered from the subsequent visits to the gas-works in both towns. On these occasions very generous hospitality was extended to the members, who are indebted to the President of the Association, Mr. L. J. Langford, and Mrs. Langford, and also to the Chairman and Directors of the Portsmouth Gas Company, for their kind entertainment, which was highly appreciated.

The reports on commercial topics continue to be of great interest to the members at the monthly meetings; and the information which is available on these occasions regarding the state of the bye-product markets indicates that the time devoted to the discussion of these matters is most usefully employed.

Papers of a high standard were presented by members on technical subjects, which embraced interesting features in the processes of manufacture and the distribution of gas. Among the papers were included the following: "Use of Steam in Purification," "Sulphate of Ammonia Propaganda," "Modernizing Gas Cookers," "Competition from Coke-Oven Coke," and "Meter Repairs." The fruitful discussion which followed the reading of these papers showed that the introduction and discussion of technical subjects at the monthly meetings are appreciated by the members and useful to the industry. The scope of the question-box has been enlarged in order to meet the desire of several members who contemplate alteration or additions to their works; and the information so supplied concerns the efficiency and working of gas manufacturing apparatus and plant. Two interesting subjects were introduced through this source during the year: "Remodelling a Carburetted Water Gas Plant," and "Installing New Vertical Retorts."

The circulation of copies of the transactions of the monthly meetings continues to be of great value to the members, and the demand for copies is increasing.

It is a source of great regret to the Committee that the monthly meetings are not more widely attended. Out of a total membership of 249 for the Eastern Section, the average attendance of 28 is not very encouraging for the officers of the Association, who are responsible for organizing the meetings; and the Committee trust that the members will endeavour to promote a larger attendance at meetings in the future.

The following District Officers were elected to serve during the coming year:

Chairman—Mr. F. Smallbone.
Vice-Chairman—Mr. J. Terrace.

Committee—Messrs. A. H. Andrews, C. Valon Bennett, W. H. Bennett, A. Caddick, T. Carmichael, C. Chambers, A. G. Cheal, S. Lacey, L. J. Langford, R. H. Ruthven, C. H. Rutter, A. W. Sumner, J. S. Thorman, and W. H. Warren.

Two members to represent the Eastern District on the General Committee, in place of those retiring by rotation—Messrs. A. H. Andrews and W. H. Bennett.

Hon. Secretary—L. Trewby.

The total membership of the Section is 249, of which 117 are representative members, and 132 ordinary members.

A. H. Andrews, *Chairman.*

FIFTH ANNUAL REPORT OF THE COMMITTEE OF THE WESTERN DISTRICT.

During the year eight meetings have been held, seven at Exeter and one at Exmouth. The attendance at the meetings has been fairly satisfactory, but slightly below the average for 1923.

Most of the matters relevant to the general trend of the gas industry have been discussed, and members have, to a great extent, benefited by such discussions. The future of the Association in the West is well assured, as we have almost a 100 p.ct. membership; and though some meetings have produced small attendances, others have proved of such interest as to merit the presence of thirty mem-

bers, which is very satisfactory considering the distance some have to travel.

The following members were elected as District Officers to serve during the coming year:

Chairman—Mr. C. G. Dawson.

Vice-Chairman—Mr. J. H. Cornish.

Committee—Messrs. J. Armstrong, S. E. Halliwell, H. Higham, P. S. Hoyte, J. Harger Pye, H. E. Riley, J. Taylor, W. P. Tervet, E. P. Vince, and J. Wesley Whimster.

Hon. Secretary—W. E. Dean.

Representative on the General Committee, in place of Mr. R. Robertson (appointed Vice-President)—Mr. W. E. Dean.

In regard to the year 1925, everything points to a renewed interest in the affairs of the Association; and it is hoped that the members will support the meetings as regularly as before.

S. E. Halliwell, *Chairman*.

Mr. W. H. Bennett Honoured.

Mr. L. J. Langford (Tunbridge Wells) said that, on behalf of the Association, he was entrusted with the pleasing duty of thanking Mr. W. H. Bennett, of Redhill, for his devoted and most valuable services to the Association during the time he had been their Hon. Secretary. This was a privilege of which he was extremely proud. His only claim to it, however, was that he happened to be the last of the five fortunate Presidents to occupy the chair during Mr. Bennett's term of office; and though he felt the present President (or any of his own predecessors) would have made these acknowledgments more gracefully, he was too utterly selfish to waive his own thin claim. Members fully appreciated that much of the progress of the Association had been dependent upon the energy, ability, and resource of the Hon. Secretaries; and they wished to do honour that day to one who had given of his very best for the past five years in this capacity. It was no sinecure for any man to undertake the office five years ago. At that time engineers had much leeway to make-up on their works and districts consequent upon the war; and, looking back, one might well have imagined that this would have adversely affected the Association's interests. But what did they find to-day? He knew they would agree with him that the period had been a very critical one, and that the Association's activities were never more lively. The membership during that time had increased from 241 to 304, or 26 p.ct.; and they heartily congratulated Mr. Bennett on the realization of his ambition in this important matter. He asked for the 300, and he got them; so that they saw their Association the largest of the Senior Associations—a fact of which they were justly proud. There was a wealth of truth in the old saying: "If you want a job done, and done well, get a busy man to do it." This had been amply demonstrated in the present case; and he sometimes thought their friend's spirit asked too much of his physical powers. They knew his activities were many, and his enthusiasm boundless for any matter in which he interested himself; and his indefatigable work for their Association in particular, together with his unfailing kindness and courtesy, would long be remembered by every one of them. Mr. Bennett's popularity was not confined to their Association, but extended to the sister Associations; for he had freely given of his time to visit those in the North, the East, the West, and the Midlands. They all desired not only to thank him, but to express their appreciation of his services in practical form. The letters he (Mr. Langford) had received in response to the circular issued on behalf of the Committee bore eloquent testimony to the esteem in which he was held by the members; and the proposal to elect him an honorary member of the Association, for which he had so successfully and unselfishly laboured, was heartily endorsed. He therefore had the greatest pleasure in moving that Mr. W. H. Bennett be elected an honorary member of the Association.

Mr. W. N. Westlake (Exeter) remarked that he had probably only one qualification for seconding this resolution—namely, that of representing to some extent the Western Section of the Association. It would be within the recollection of most of those present that Mr. Bennett took charge of the Association as Hon. Secretary a short time after it was reorganized, and it was just a question then as to whether or not the re-organization would be a failure; but with such an energetic Hon. Secretary as Mr. Bennett, he did not suppose one of them felt any real doubt on the matter. And they were justified in their faith, for success had come. It had enabled the Association to enlarge its usefulness to the industry, and much of this enlargement was due to the work Mr. Bennett had put into it. He would like especially to say how very much the Western Section appreciated the help he had given them. On many occasions he had taken the trouble and spared the time to journey down and attend the meetings.

The resolution having been passed with acclamation,

Mr. Langford said: Mr. Bennett, we are under a great debt of gratitude to you; and in thanking you most heartily for your devoted services to this Association, we ask you to accept honorary membership, and also these field glasses and cigarette case, which we trust you will find of service and will be to you mementoes of this occasion. They are small tokens, not only of our deep gratitude, but of our personal affection and esteem. May the future hold for you all you so richly deserve. May you live long and enjoy good health; and may the Southern Association have the advantages of your active support for many years to come.

[The cigarette case was gold, with a monogram in platinum.]

Mr. W. H. Bennett (Redhill) said he found difficulty in adequately thanking them for the great honour they had done him in making him an honorary member of the Association, and also for the valuable gifts. It was fortunate, perhaps, that he was not called upon to decide which appealed to him most; but he was sure they would not misunderstand him when he said that nothing they could give him would afford him so much pleasure as having bestowed upon him the freedom of the largest District Association. As they had heard, this was the jubilee year of the Association; and during these fifty years only some half-dozen of the members had been placed upon the Roll of Honour. Of these only three were on the list that day, and they were men who had done great service, not only to the Association, but to the industry as a whole. They could realize, therefore, how greatly he appreciated the honour that had been done him—particularly as he was the only one to receive this honour while still in active service. As to the handsome and useful gifts, no better choice could possibly have been made. He would always regard them as tangible proofs of the goodwill of the members; and when using them, as he hoped to do for many years to come, he would reflect on the many kindnesses he had received at their hands during the past five years. What he had done in this period had fallen far short of the ideals he had set before himself; and any success that had been attained was attributable to the encouragement and support received from the members. His thanks were due to his confidential clerk, Mr. Alfred Gear, who had done a lot of work, with entire satisfaction to him (Mr. Bennett) and the Association. Mr. Ernest Scears, the Engineer to the Company, had also on more than one occasion lent valuable help, for which he thanked him.

The Late Mr. A. F. Browne.

The President said that, as they were no doubt all aware, unfortunately since the last meeting they had lost one of their oldest and most esteemed members in Mr. A. F. Browne. Members would be glad to know that a wreath was sent on behalf of the Association, and that the Association were represented at the funeral by Mr. A. H. Andrews. He was sure those present would like to pay a tribute to the memory of their departed friend.

This the members did by standing silently in their places.

New Members.

The Hon. Secretary (Mr. H. C. Smith, of Tottenham) read the following list of names of new members, who were elected on the proposition of the President, seconded by Mr. R. Robertson (Bristol):

Mr. Frederick James Falkner, Manager and Secretary to the Romsey Gas and Coke Company, Ltd.

Mr. Henry Cecil Ratcliffe, Assistant Engineer and Chemist, Romsey Gas Company.

Mr. John Alfred Brentnall, Engineer to the Northfleet and Greenhithe Gas Company.

Mr. Douglas Forbes Irving, Engineer and Manager to the Leatherhead Gas Company.

Mr. Roy Forbes Irving, Works Superintendent, Poole, and Assistant Engineer to the Bournemouth Gas and Water Company.

Representative on the Institution Council.

Mr. P. S. Hoyte (Plymouth) proposed that the President be elected the representative of the Association on the Council of the Institution of Gas Engineers for the current year. Why had they waited, as an Association and as an industry, until now before electing a man occupying the position Mr. Moon did, with one of the most progressive undertakings of the country, to take his seat for the first time on the Institution Council? Probably the explanation was that Mr. Moon had not yet had the time to take that position in the affairs of the industry as a whole which they hoped in future he would find opportunity to occupy. The Bournemouth Gas and Water Company were developing at an extraordinary rate—almost unprecedented, he would say, for an undertaking of that size, in the history of the industry—and Mr. Moon's energies must have been absorbed by this development.

Mr. J. Wesley Whimster (Bath) seconded the resolution, which was agreed to.

Presentation to the Immediate Past-President.

The President said it was now his pleasant duty, on behalf of the members, to thank their immediate Past-President, Mr. Langford, for the excellent way in which he had conducted the affairs of the Association during the past year. It had been one of the most successful years in the history of the Association—due partly to the cheery good-fellowship of Mr. Langford, and partly to the quality of the programme he had provided for them. ["Hear, hear."] They all remembered, too, the

very pleasant visit they paid to his charming town and works, and the hospitality enjoyed at the hands of his Directors; and they had also in mind the additional visit paid to the Portsea Island Works—a visit which, thanks to the hospitality of the Directors and the excellent works that Mr. Carmichael had to show them, marked a red-letter day in the history of the Association. Mr. Langford had worthily upheld the high traditions of the office, and he had the privilege of presenting to him a suitably engraved silver salver as a memento of his year as President. [Applause.] They all felt that he heartily deserved it, and hoped it would serve to remind him of a very pleasant year of office.

Mr. Langford, returning thanks, said he was indeed grateful for the nice things that had been said about him. He could only tell them that he was inexpressibly proud to have occupied the presidential chair of the Association. Any success that had attended his efforts was due to the support so generously accorded him. He sincerely thanked the President, Committee, and members for this support—and especially those who came forward so willingly with papers. The salver so kindly presented to him would, as long as he lived, be one of his most cherished possessions, and bring back to him memories of a very happy year of office and of the host of friends he had made during that year.

Mr. Moon then proceeded to deliver his Presidential Address, which was in two parts. The second part was a description of the new gas-works of the Bournemouth Company at Pitwines, which the members will inspect later. [This description will be included in next week's issue.]

PRESIDENTIAL ADDRESS.

My first duty must be to thank the members of the Southern Association of Gas Engineers and Managers for the honour they have done me in electing me to the responsible position of their President for the ensuing year. The position has been filled by so many distinguished gas engineers in the past that the task of adequately upholding the dignity and traditions of the office is one which may well cause the average man much

THE PRESIDENT.

Mr. P. G. G. Moon, F.C.S., of Bournemouth.

anxious consideration. Fortunately for my peace of mind, I have great faith in the kindliness and the capacity for making allowances of the members of this Association; and so I am content to do my best and leave myself in their hands.

One of your former Presidents—I think it was Mr. Campbell—referred to the fact that most members regard a Presidential Address as a somewhat uninteresting proposition. I am inclined to agree—especially on this occasion—although in his own case Mr. Campbell proceeded to demolish his contention by giving an exceedingly interesting address. I think that the feeling—which undoubtedly exists—probably arises from the fact that no discussion of the subject-matter of the address is permissible. Subject to your approval, therefore, in order to overcome to some extent these objections, I propose to divide my remarks into two parts—one a short Presidential Address proper; the other a paper dealing with the new gas-works of the Bournemouth Gas and Water Company at Poole, which you will, I hope, see during your visit to Bournemouth. At the same time, I should like to voice my personal view that, even if it breaks an unwritten law, it would usually be a distinct advantage to the industry to open the subject-matter of all Presidential Addresses to discussion.

GAS SALES PROGRESS.

It must be a source of considerable satisfaction to every gas engineer to see the extraordinary progress that is being made in the sales of gas throughout the country. Even those of us who have most consistently sung the praises and possibilities of gas, must be surprised and gratified at the progress it is making. The shortage of household labour—the improvement in the design of gas apparatus—the increasing desire to mitigate the "smoke nuisance" in towns, coupled with the excellent work of the "B.C.G.A." in bringing the advantages of gas before the householders of the country in a dignified and convincing way, have all resulted in a wonderful wave of popularity for gas.

The figures for Bournemouth of the gas made and the consumption per consumer for the years 1904, 1914, and 1924 are given below:

Year.	Gas Made. Millions.	Gas Sold. Slots. Consumers.	Slots. Consumption.	Ordinary. Consumers.	Ordinary. Consumption.	Total. Consumers.	Total. Consumption.
1904	572·089	7,064	13,420	7,085	59,670	14,149	37,280
1914	1114·807	16,320	16,180	12,179	61,810	28,499	35,650
1924	1971·039	17,967	29,880	18,395	68,200	36,362	49,260

The satisfactory thing about these figures is the consistent increase in the consumption per consumer, as well as in the number of consumers. As some indication of the reasons for this steadily-increasing consumption, figures are given in the following table for the sales of gas apparatus in the Bournemouth area of supply for the past few years, as well as the summary of houses under construction during 1924.

Year.	Total Sales.	Cookers.	Fires.	Water Heaters.
	£			
1921	29,099	828	1570	243
1922	33,920	1150	2332	364
1923	42,956	1397	2944	523
1924	48,321	1743	3419	799

Summary of Houses Under Construction, 1924.

Number of Houses Started During Year.	Number Completed During Year.	Number Incomplete.	Piped Only.	Wired Only.	Pipe and Wired.	Houses Already Occupied.
1495	1196 (including 296 started in 1923)	595	593	1	602	1042
			1196			

	Cookers.	Lights.	Fires.	Boilers.
Points	1220	5196	2552	293

Bournemouth is, I know, a particularly favoured town, but figures of a similar character could no doubt be quoted by practically all our members. It is, I think, safe to claim that the "right atmosphere" has certainly been created throughout the country for increased gas sales; and given the necessary propaganda work on the part of an undertaking, an adequate response by the consumers is to-day fairly certain.

GAS, ELECTRICITY, AND POLITICS.

Much is read at every election, and in the election programmes of every party, of the wonderful results that are to accrue to the nation as the outcome of the super-electricity schemes put forward as planks in the various political platforms. Our brilliant, useful, but very extravagant (from a thermal efficiency point of view) younger brother receives all the attention; and in spite of an excellent Fuel Research Board, who can provide all the scientific facts for those who care to ask for them, none of the leading politicians seems to realize that the elder brother, gas, occupies a far more important place in the political economy of the country's fuel supply.

They appear to be quite unaware of the fact that, not only is the gas supply of the country very much larger, but it is also much more efficient from a thermal efficiency point of view, than the electrical supply. If they fully grasped the underlying thermal facts, they would realize that the greatest good to the nation would probably come by putting the two brothers into business together. Each fills an important place in the country's needs, and by working together the greatest efficiency of the dual operations would be most readily obtained.

Consider the figures for the electric supply undertakings for 1923 (the latest figures available at the time of writing):

Stations.	Fuel in Tons.	Units Generated. Millions.	Equivalent Therms. Millions. (Elec. Unit = 3412 B.Th.U.)	Average Coal Consumption per Unit. Lbs.	Lowest Coal Consumption per Unit. Lbs.	Highest Thermal Efficiency. P.Ct.
463	7,356,757	4955	169·4	3·32	1·70	17·7

Now contrast these with the yield from the same weight of gas coal carbonized in a modern gas-works:

Coal Carbonized. Tons.	Gas at 70 Therms per Ton. Mills. of Therms.	Coke at 10 Cwt. Made for Sale.	Tar at 10 Galls. per Ton. Gallons.	Sulphate at 20 Lbs. per Ton. Tons.
7,356,757	515	3,678,000 tons at cal. value of 12,000 B.Th.U. per lb., 989 million therms	73,000,000	65,685
	1504 million therms			

Comment as to the increased thermal yield is superfluous—the figures are sufficiently striking to speak for themselves. In addition, there is the splendid yield of tar and sulphate to put to the credit of the gas balance-sheet.

The average efficiency of the electric supply undertakings is just over 8 p.ct. The most optimistic claims of the super-station are in the region of 20 p.ct.; and if these claims could be realized throughout the country, the equivalent thermal output of electricity from the same tonnage of fuel would be 425 million therms. But gas on the same tonnage, under *present conditions,* gives 515 million therms—apart from the 989 million therms in the coke and immense quantities of valuable residuals! The coke from the above gas balance-sheet, if turned into producer gas and used for the generation of electricity, would generate 2747 million units of electricity. The moral is obvious!

For the purpose of comparison, it is interesting to note the figures for the Gas Light and Coke Company for the same year—1923:

Year.	Gas Sent Out in Million C.Ft.	Calorific Value.	Equivalent Total Therms per Annum in Millions.
1923	36,570	500 B.Th.U.	182·8

As Mr. Milne Watson has pointed out, that Company alone sent out a greater number of heat units than the heat equivalents of the electricity sent out by all the electricity undertakings of Great Britain in the same year. The gas sent out during 1923 by the gas industry as a whole was as follows:

Year.	Gas Sent Out in Million C.Ft.	Average Calorific Value, say	Equivalent Total Therms per Annum in Millions.
1923	259,849	475 B.Th.U.	1234

Coal used	16,460,632 tons.
Coke made for sale—	
Net	8,197,347 tons, approx.
Equal to	2,200 million therms.
Tar	181,962,574 gallons.
Sulphate of ammonia . . .	117,166 tons.

The electrical industry is, perhaps, not so efficiently organized for commercial sales operations as the gas industry. I do not think they have any organization doing nearly such effective work in such an excellent way as the British Commercial Gas Association; but they do appear to be able to get the political ear of the country in a far more definite way than does the gas industry.

Mr. Milne Watson in his remarks as Governor at the recent annual meeting of the Gas Light and Coke Company, Sir Dugald Clerk in his classic paper before the Society of Arts in 1919, Mr. Reginald Clarry in the House of Commons, Sir Arthur Duckham on many occasions, and Col. Woodall and Mr. Seabrook in their work on the combination of gas and electricity undertakings—have all in various ways drawn attention to the vital issues involved.

What is required, however, is a co-ordinated effort; and I think the time is over-ripe for the formation of a permanent Committee drawn from the leading administrators, engineers, scientists, and publicists of the industry, whose definite duty it should be to impress upon the country by means of lectures by eminent scientists, by newspaper articles and pamphlets, and by representations to all political parties, the fundamental thermal facts of gas manufacture and electricity generation, and their effect upon the nation's fuel resources.* I hope my remarks will not be interpreted as in any way belittling the great and growing importance of electricity and the part it plays in the home and industrial life of the nation.

Of the importance of electricity, and of the good that must come from a cheap and abundant supply, there can be no question. The important thing is to see that the thermal value of the coal which is the prime source of our nation's power is conserved to the uttermost, and that the thermal efficiency of every major operation of which it forms part is carefully investigated. From such a standpoint as this, not electricity, but the present methods of generating electricity, stand condemned.

Improved Methods and Research Work.

The preferential position occupied by gas suggested by my previous remarks must not lull us into a false sense of security. It should, on the contrary, imbue us with an increased sense of the industry's responsibility. The need for research work to the end that our methods may be improved was never greater than it is to-day. The problems that confront us are not those of the engineer and manager alone; they become more and more the direct concern of the physicist and chemist; and we should all do what we can to encourage research work on the small scale on our own works, and on the wider scale in those Universities, such as Leeds, which specialize in gas problems.

PURIFICATION.

The purification of gas, involving principally the removal of sulphur and ammonia, is, broadly, to-day what it was twenty years or more ago. We are still content to remove the sulphur by means of oxide of iron, sell the spent oxide to the acid maker, and buy back from him sulphuric acid to use in the manufacture of sulphate of ammonia. I say we are still content to do this—that, perhaps, is not quite correct. We do it because no alternative method is available. It is an expensive and wasteful business, enriching the railway companies and the acid manufacturers at the expense of our consumers.

Any research that will teach us how to utilize the sulphur in our gas by direct application, will benefit the gas industry greatly.

BURKHEISER PROCESS.

It is worth reminding members shortly of the work done in this direction before the war by Herr Burkheiser. In his process, which was working satisfactorily on a stream of ¾ million c.ft. of coal gas per day at the Tegel Works in Berlin, the crude gas, after the extraction of tar, and while still containing both sulphuretted hydrogen and ammonia, was passed through a series of comparatively small purifiers containing dried nodules of oxide of iron about the size of peas. The sulphur was extracted, and the gas containing ammonia was passed first through a wrought-iron saturator, and then through a vertical scrubber containing a solution of sulphur dioxide.

The sulphur dioxide solution came from another scrubber, through which passed the air and sulphur dioxide from the particular purifiers undergoing regeneration. The regeneration of the purifiers was conducted *in situ* in a stream of air at a controlled rate, which raised the temperature sufficiently to fire the freed sulphur and burn it to sulphur dioxide, but not so high as to dehydrate completely the oxide of iron. The critical temperature was found to be approximately 600° C. After regeneration the oxide was extremely active; and for the several months that the plant was working, no serious loss of activity was observed.

The absorbing liquor was circulated continually, first through the sulphur dioxide scrubber, where it became acid, then through the ammonia scrubber, where the ammonia predominated until it reached saturation point and crystals of ammonium sulphite—$(NH_4)_2SO_3$—were thrown down in the wrought-iron saturator placed between the two scrubbers. The ammonium sulphite oxidized upon exposure to the air to a stable salt composed approximately of two-thirds sulphate and one-third sulphite. This compound was richer in nitrogen than "straight" sulphate, and experiments proved it to be in all respects equal to sulphate in proportion to its nitrogen content.

This process was particularly attractive, in that it reduced the size of oxide purifiers to about one-twentieth of the ordinary size, utilized the sulphur direct, and did away with the need for expensive ammonia stills and lead saturators. Many tons of salt were made in Berlin, and some at Bournemouth, by this process. Chemically the process was without flaw, and the gas routine gave no trouble; yet it broke down principally on account of the difficulty of securing oxide nodules that would stand-up to the changes of temperature. They tended to break-down ultimately to dust, which gave excessive back-pressure, and led to irregular fouling and regeneration.

Many experiments were made without success to produce oxide impregnated materials that would permit the chemical process to take place, and yet not disintegrate under the heat. The process, however, was so promising that it really seems that further research is well worth while, and might lead to a more successful result.

CURPHEY'S PROCESS.

Another attempt to utilize the underlying principles of the Burkheiser process was made by Mr. Curphey (when Chief Alkali Inspector) and Mr. Linder. In a suitable furnace they burnt the sulphur in spent oxide fouled in the ordinary oxide purifiers, and passed the resultant sulphur dioxide through a scrubber. The acid liquor was used to absorb the ammonia from an ordinary sulphate still. After circulating a number of times, the concentration was sufficient to crystallize out ammonium sulphite crystals which oxidized to the two-thirds sulphate and one-third sulphite compound.

The chief difficulty with this process, as tried-out on an experimental scale for Mr. Curphey at Bournemouth, was to reduce the amount of water vapour coming forward with the

* Since writing the above, I understand that a small Committee of distinguished men has already been formed for this purpose. This is a matter for congratulation; and the work they have taken up needs all the loyal support and help that we can individually give.

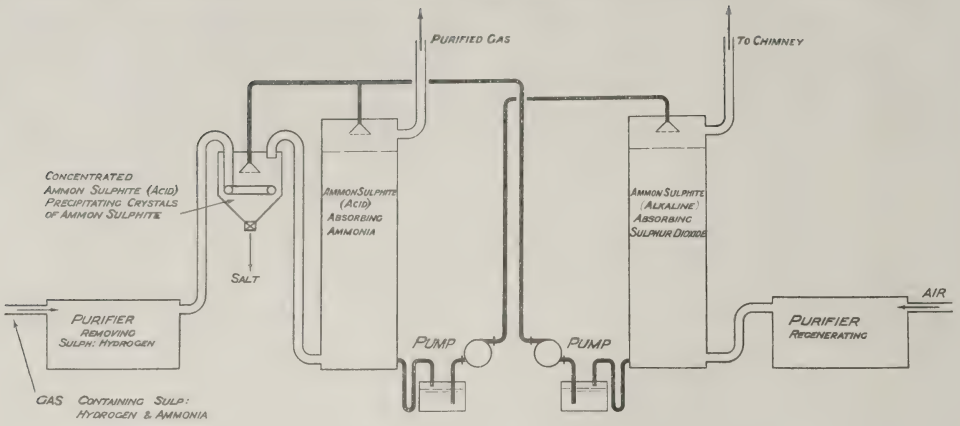

DIAGRAM OF BURKHEISER PROCESS.

ammonia to an extent sufficient to prevent undue dilution of the ammonium sulphite solution. Even if successful, this process was much less complete in its conception than the Burkheiser system, since it retained the existing oxide purifiers and sulphate still. It would nevertheless have utilized the sulphur direct on the gas-works without the intervention of the railway and the acid works—a quite useful advance on our present methods.

LIQUID PURIFICATION.

The liquid purification process developed by the Koppers Company in the United States of America, and licensed in this country to the Woodall-Duckham Companies, was a system which made possible the continuous purification of gas from sulphretted hydrogen by liquid reagents in closed vessels. It comprised two stages. In the first stage sulphuretted hydrogen was absorbed from the gas by means of an alkaline solution in a tower scrubber. In the second stage the solution was revivified in another tower scrubber by a current of air and the sulphuretted hydrogen liberated and discharged into the atmosphere, either direct in an extremely diluted form or by way of boiler furnaces in which the sulphuretted hydrogen was burnt to sulphur dioxide. The process could not be exploited in this country, since the Alkali Inspector very properly would not permit the sulphur removed from the gas to be discharged into the atmosphere either as sulphuretted hydrogen or sulphur dioxide.

Several large-scale plants operating on the above lines in the United States have experienced difficulty under certain atmospheric conditions; and in consequence the Koppers Company have been experimenting with the object of evolving a modified process to meet the difficulty. They have had considerable success, and hope to be able in the near future to have available on the above lines a process modified so that the sulphur will be recovered directly in a marketable form.

Generally, enough has been said, I think, to indicate the fruitful field that awaits the investigator in purification methods, and the desirability of stimulating research in this direction. In addition, there is still that other bugbear of the gas industry—or perhaps I should say of the gas consumer—which ought to be seriously tackled by every conscientious gas engineer. I refer to the organic sulphur compounds. Dr. Carpenter has evolved one process that satisfactorily removes them; but it is unfortunately a somewhat expensive and cumbersome one. Nevertheless, I feel strongly that until, either by this or by some other process, these sulphur compounds are removed from the gas, for so long will it fall short of being the perfectly satisfactory source of light and heat that it ought to be.

OIL CRACKING.

Another direction in which research work is desirable is that of investigating some means of increasing the efficiency of "oil cracking" in our water gas enrichment operations. The present method of spraying oil on to the red-hot brickwork of the carburettor has the merit of simplicity, but, unfortunately, labours under the disadvantage of low efficiency.

Ignoring the heat absorbed in the cracking operations, on the ground that it is largely waste heat, the thermal efficiency of the present method appears to be approximately as follows, with oil of calorific value of 18,000 B.Th.U.:

	P.Ct.
Gas enrichment	52
Oil tar, 15 p.ct. of oil used, cal. value 16,000 B.Th.U.	13
Loss	35
	100

When it is remembered that, even in a provincial company of the size of Bournemouth, the gas-oil bill is in the neighbourhood of £20,000 a year, it will be realized what an important financial bearing any considerable increase in oil cracking efficiency would have upon manufacturing costs.

NELSON PROCESS.

Some interesting tests were made at Bournemouth last year on a small experimental oil-cracking plant embodying the patented ideas of Mr. John Nelson. In this process gas oil is passed through a series of small vertical iron retorts, each containing a lead bath heated to a determined temperature, and with a certain amount of free space above the lead. The products of this process are oil gas, motor spirit, and carbon black of a particularly pure quality.

Two typical balance-sheets of the results obtained are given,

FIRST TEST.—*Maximum Motor Spirit Production.*

OIL PRODUCTS.

	Wt. Lbs.	Therms.		Wt. Lbs.	Therms.	P.Ct. of Total Therms.
34 galls., s.g. 0·86, cal. val. 18,000 B.Th.U. per lb.	290	52·3	Gas.—990 c.ft., s.g. 0·94, cal. val. 1500 B.Th.U.	72	14·8	28·3
			Motor spirit.—15·0 galls., s.g. 0·82, cal. val. 18,500 B.Th.U.	123	22·7	43·4
			Oil residue.—9 galls., s.g. 0·93, 16,000 B.Th.U. per lb.	84	13·4	25·6
			Carbon black.—Av. cal. val. 14,500 B.Th.U.	2	0·3	0·6
			Loss	9	1·1	2·1
	290	52·3		290	52·3	100·0

SECOND TEST.—*Maximum Gas Production.*

OIL PRODUCTS.

	Wt. Lbs.	Therms.		Wt. Lbs.	Therms.	P.Ct. of Total Therms.
30 galls., s.g. 0·86, cal. val. 1800 B.Th.U.	258	46·5	Gas.—2730 c.ft., s.g. 0·972, cal. val. 1250 B.Th.U.	177·7	29·65	63·80
			Motor spirit.—3·375 galls., s.g. 0·82, cal. val. 18,500 B.Th.U.	26·85	4·98	10·69
			Oil residue.—4 galls., s.g. 0·06, cal. val. 16,000 B.Th.U.	38·40	6·15	13·20
			Carbon black.—Cal. val. 14,500 B.Th.U.	4·24	0·62	1·33
			Loss	10·81	5·10	10·98
	258	46·5		258·0	46·50	100·00

one with the conditions arranged for maximum motor spirit production, and the other for maximum gas production. As so much waste heat is available in a water gas plant, no allowance has been made in either case for the heat used in cracking.

These results are interesting; and in the test for maximum gas production it is shown that an increase of over 10 p.ct. is obtained in the thermal value of the gas produced, as compared with present practice, as well as an increased supply of bye-products of a much more valuable character than the present rather troublesome oil tar.

The above increased thermal value of over 10 p.ct. is, of course, calculated on the total thermal value of the oil. From the gas manufacturers' point of view, the process improves the gas carburation from 52 p.ct. to 63 p.ct.—that is, 11 on 52, or 21 p.ct. increased efficiency compared with the existing system.

The chief drawback to the process—and it is largely one of policy—is that, in a works using (say) one million gallons of oil a year, the annual production of a motor spirit on the second balance-sheet would be in the neighbourhood of 30,000 gallons—and this could be largely increased at the expense of the oil gas by a regulation of the cracking heats as shown on the first balance-sheet.

The disposal of this motor spirit would obviously involve difficulties with the oil companies, who are themselves suppliers of motor spirit as well as gas oil. The way out of the difficulty would appear to be for the oil companies themselves to investigate and perfect such a process, and to standardize a plant designed to use waste heat that could be put down on a gas-works to the mutual advantage of both parties. The gas companies have the waste heat available for cracking the oil, and a use for the oil gas produced; while the oil companies need petrol for selling in the surrounding districts.

CARBONIZATION AND COAL.

Then there are the many problems awaiting solution in that complex process which is the basis of our operations—the carbonization of coal. We have the interesting researches of Dr. Lessing on the composition and impurities of coal and the possible effect upon the carbonizing process of the chemical composition and physical condition of the ash—the possible effect of largely freeing the coal from these impurities—the character and composition of the various constituents of coal proper and their reaction towards heat—all full of very real significance as to how they may affect the production from the coal of the maximum thermal yield in the form of gas.

We have the problems that surround the many attempts to deal satisfactorily with the complete carbonization of coal—problems which arise largely from the fact that the water gas reaction, which is the necessary concomitant of such a process, is endothermic. A liberal supply of comparatively pure oxygen at a sufficiently low price would solve the difficulty; but it is easier to point to the requirement than to satisfy the need.

These and many other problems that will readily occur to every listener await solution, and I suggest that the gas industry is big enough, and has enough to gain, to make it worth while, and ought to be enterprising enough to put-up a really large research fund that would enable these problems to be tackled in a much bigger way than the present restricted resources permit. Splendid work is being done now; but there is not enough of it, and that through no fault of the distinguished scientists who, at the present time, work in our interests.

COKE.

Coke is the residual which most affects the balance-sheet of any gas undertaking; but it does not always receive the attention that it deserves from those responsible. It is almost as important to push the sale of coke and to popularize its use as it is to push the sale of gas. We are passing through a period of considerable depression in the coke market; and it is eminently desirable that all gas undertakings should conduct a vigorous campaign in their own area—pointing out the advantages of the use of coke as a smokeless fuel—in their own interests, and in the interests of the industry generally.

CONCLUSION.

I have said nothing about such important questions as legislation, changes in statutory requirements, revision of standard price, wages, &c., because I felt that these are matters belonging properly to the National Gas Council and the Federation of Gas Employers; and there is already far too much overlapping and far too many meetings for the busy gas engineer to wish to waste time at a technical meeting in considering matters which are adequately dealt with by their appropriate associations.

This brings me to a subject which I suppose affects every member here to-day. That is the difficulty we all find in carrying out fully and energetically the increasing duties and responsibilities of our positions as gas engineers, and yet attending the many meetings of the various associations connected with our industry. There are the Institution meetings, the District Association meetings, the Commercial Sections, the National Gas Council, the British Commercial Gas Association, the Federation of Gas Employers, and many other special and incidental meetings—not to mention the committee meetings which some of us have to attend as well. They are full of interest, they all need our help and support; yet if we are to put our jobs first, as we should, we cannot possibly attend nearly all of them. It is a serious matter, and I have no sovereign remedy to suggest; but it calls for full consideration, and certainly for an understanding spirit on the part of the officials of any association when members fail to attend important meetings.

The only thing we can do at present is to avoid overlapping as much as possible. This is essentially a Technical Association; and, under present conditions, I think we should, as far as possible, try to confine ourselves to technical matters—leaving questions of policy, legislation, and wages to their appropriate bodies. Generally, I would say that there should be enough of interest and inspiration in the work of the present-day gas engineer to fill him with enthusiasm and a real love for his work. His problems are many-sided, his responsibilities are great; but his job is a live proposition, with a scientific justification for its existence, and with a fruitful promise of greater usefulness to come.

The Fuel Problem.

Sir Arthur Duckham said he had been privileged to propose a vote of thanks to their President, of whom they must be proud. In his excellent address he had dealt with subjects that were of vital and fundamental interest to the gas industry. The case he had made out for the gas industry was a wonderful one, and, in referring to it, he (the speaker) felt sure they would allow him to mention one point in the address. This had to do with the national programme for fuel development in this country from the gas point of view. He thought that they in the gas industry had lacked general propaganda, whereas they had very fine specialized propaganda; and he did not believe any of them had really formulated in their minds how a national programme of fuel development in the country should be put forward, especially from the gas point of view. A Committee were sitting on this subject, and he did hope they would come to really sound conclusions, because up to now the fuel problem had not been handled soundly in this country. It had been considered from one point of view, and he thought from a very narrow side of that one point of view. By education and propaganda, it seemed to him, this aspect could be very much widened. As to the part dealing with the works, the President had had a splendid opportunity and he had taken excellent advantage of it. Perhaps, however much they might envy him his opportunities, some of them would feel rather nervous as to taking his responsibilities. When they realized that the site of the works the President had been telling them of was formerly sea-covered; when they remembered the difficulties in connection with foundations—very grave difficulties indeed—and when they considered the whole lay-out of the works, he thought they would conclude that they knew of a place to which they could well take a friend who did not know anything of gas-works, but might be an engineer, and so able to appreciate what had been done. Mr. Moon had drawn on his own experience and the experience of others to a very full extent—especially in the wonderful handling arrangements he had installed on a very awkward site. When they visited Bournemouth and Poole—as he hoped they would all do—he was certain that the handling of the coal, coke, and ashes would interest them immensely. He had been privileged to see the works in the early stages, and to inspect the drawings; and the manner in which Mr. Moon had carried out the scheme proved him to be an engineer of very high standing. At the same time he had shown himself to be a chemist and physicist of no mean capability; and in dealing with the chemical problems of gas manufacture in the way he had done, he had overcome troubles that beset many gas engineers. He was glad to be able to say what he had, because he had been associated with Mr. Moon. Really the President was the man who started him on his travels from Bournemouth—a very nice place, with very nice people. But there was also another gentleman who must also be very proud of this address, and that was Mr. Thomas Glover, of Norwich, who must be delighted to feel that Mr. Moon, who had been with him at Norwich, should have done so splendidly as a chemist, as a chemical engineer, and as a gas engineer.

Modern Practice in Gas-Works.

Mr. W. Doig Gibb said that, in common with all the members assembled, he had listened with very great pleasure to Mr. Moon's address and to the description of the new works at Bournemouth. It was quite impossible in the time now at disposal to do more than touch the fringe of a discussion upon such works; and he suggested that at their next meeting, instead of having a formal paper, there should be a discussion on modern practice in gas-works. It would be most interesting and educative to deal with the new works in that way. He felt gratified to have been given an opportunity of seconding the vote of thanks, and of adding his personal congratulation to Mr. Moon. Many years ago he became acquainted with Mr. Moon, and had known him intimately since. Even in those early days he knew that Mr. Moon was a man who was to make good. He had certainly made good, and in making good had carried with him the respect of his brother gas engineers. He was a congenial companion, he was a well-read man, and from what he had been telling them he was evidently a good and sound engineer. [Applause.]

A Wonderful Proposition.

The President, returning thanks, remarked that it was somewhat embarrassing to hear all these things. He felt that, while he had done his best to deserve something, he had not deserved nearly all that had been said. It was gratifying to think the address had been regarded as not without interest. The gas industry at the present time was a wonderful proposition for people who were keen, and who wanted to make an impression on the problems that lay around them. He knew of no man who was more in love with his job than the average gas man one met. This became more and more marked every year. It was a splendid sign—a sign of a thoroughly sound industry; and it was a promise of future progress. There was little need for wonder that people should have love for their jobs when they got such magnificent receptions as the members had been good enough to give him. He did not know whether they would like to consider Mr. Gibb's proposal. It might be cutting-out a possible paper from another member; and the more papers they could get, the better it would be for the Association.

Mainlaying Methods at Pitwines.

Mr. A. W. Sumner (Grays) said he could understand that the mains must have been a source of anxiety. Not only was it a question of having to protect them from any corrosive matter, but there was the weight to consider. Had precautions been taken to support the mains in any way by raft, or in some other manner?

The President replied that naturally, as one could imagine on a site covered with several feet at least of clinker, and under that again several feet of mud, the question of mains gave considerable anxiety. Having regard, however, to the fact that they had already had a certain amount of experience on a different part of the same site with mains laid on this more or less floating reclamation material, they decided to take their courage in their hands and simply lay the mains in clinker, protected by clay, and with lime dressing from the waterworks softening plant so as to neutralize any acidity that might be set-up by the ashes. They judged from past experience it was pretty well a case of a floating raft. There was a certain slight movement, but no settlement at any one point sufficient to cause fracture of the mains.

The Address to be Discussed.

Mr. J. Terrace (Lower Sydenham) was sure it was the feeling of the meeting that they should have further opportunity of discussing so important a contribution; and he hoped the Committee would take into consideration the proposal put forward by Mr. Doig Gibb. The description of the works had been most interesting.

Mr. C. F. Botley (Hastings) associated himself with this expression. There were doubtless many points on which they would like further information. He congratulated the President on his excellent work.

Mr. Langford supported the proposal that Mr. Moon's contribution should be discussed at a future meeting, and it was unanimously agreed to.

Government and the Electrical Supply Industry.

The Hon. Secretary read a letter from the Manchester District Institution of Gas Engineers with reference to the proposals of the Government for financial assistance for the electricity supply industry, pointing out the necessity for protecting the interests of the gas industry and gas consumers.

After a short discussion, the following resolution was unanimously passed, on the proposition of Mr. Botley, seconded by the Hon. Secretary:

> "That while this Association learns with pleasure that a small Committee of distinguished men has been formed to consider the position of the gas industry in relation to the electrical industry and the suggested subsidy to the latter, it wishes to urge that this Committee should take the necessary steps to impress the position upon the country by means of lectures, newspaper articles, &c., and most particularly by putting the true economic facts with regard to both industries before Members of Parliament.
>
> "This Association further urges that the latter action be taken without any delay, as it feels that, while the gas industry has nothing to fear from the fair competition of the electrical industry, the booming of the latter for political purposes, if allowed to proceed any further without strong opposition, can only end disastrously for the country as a whole."

"B.C.G.A." SCOTTISH CONFERENCE.

A GOOD GATHERING AT GREENOCK.

Promoted by the British Commercial Gas Association, a successful conference, which made a direct appeal to those interested in the development of the gas industry in the urban centres of Scotland, was held in the Town Hall, Greenock, on Tuesday, March 24. The President for the day was Bailie Wm. Millar (the Convener of the Greenock Corporation Gas Committee); and he was supported by Mr. W. M. Mason (Manager of the "B.C.G.A."), Provost Brown (of Greenock), Mr. J. D. Keillor (Gas Engineer, Greenock), and Mr. J. W. Napier (Gas Engineer, Alloa.)

When the proceedings opened in the morning, upwards of seventy gentlemen, largely representative of gas interests in different parts of Scotland, were in attendance.

A Civic Welcome.

Provost Brown, at the outset of the proceedings, extended on behalf of the Corporation a hearty welcome to the members to the town of Greenock. He hoped and believed that they would have there an interesting and instructive conference. In his view, there was a great field for a cheap commercial gas, and conferences which had for their objective the furthering of this end were deserving of every possible encouragement.

The Presidential Address.

Bailie Millar, in the course of his address, said it gave him unbounded satisfaction to know that the Greenock Gas Department was sufficiently in the vanguard of the industry to merit such a visit. It was with pride the citizens and councillors of Greenock looked back to find that 98 years ago the people there were alive to the possibilities of gas as a heating and lighting agent; for in 1827 a scheme for the introduction of gas was considered and passed. Since then Greenock had never looked back. Year by year the output of gas had increased, and it was their joy locally that the undertaking had come to be regarded as one of the soundest financial concerns in the country. The book value of the undertaking was only £120,000, but the actual value was over £500,000. During the past decade alone, the output of gas had advanced from 410 million c.ft. per annum to 600 million c.ft.—an increase of approximately 45 p.ct. This certainly augured well for the future, and redounded to the credit of the Corporation as well as past and present Gas Managers. Such a wonderful record of valuable public service was surely deserving of special notice. It was a point worthy of note that in Greenock the increased use of gas coincided with the opening of a spacious showroom. There could be little doubt that the foresight of the Town Council in building and equipping such a fine showroom for the use and education of the ratepayers had been fully justified. It was an asset the commercial value of which it was impossible to estimate. Without such an opportunity of displaying the latest types of gas appliances, the public would never have benefited to the extent they had done. Over a hundred people visited the showroom daily to ask for advice on all matters relating to the use of gas. As a communal undertaking it was incumbent upon them to experiment with, and test, all new appliances before recommending them for public use. In this way the public interest was protected and consumers avoided having shoddy goods foisted upon them. The specialized knowledge and experience of the technical staff were also available for the asking; and, in his opinion, they were extremely fortunate in their choice of staff, the members of which were respected throughout the industry. He was advised by the Engineer that the maintenance staff of the public service department were accomplishing extraordinarily good work among all classes of consumers; and he was strongly of opinion that service of this kind was a boon and a blessing, not only to the consumer, but to the undertaking as well. The gas industry was represented last year at Wembley; and, as other undertakings, they in Greenock contributed their share to this enterprise. So convinced were they of the importance of such co-operative propaganda, that they were this year again contributing to the Empire Gas Exhibit, in the hope that they would enjoy even better results than last year.

Aims of the Association.

Mr. W. M. Mason, in the course of a statement regarding the work and policy of the Association, said that the three great obstacles to the widespread adoption of gaseous fuel were ignorance, prejudice, and competition. The first two of these were being gradually, but surely, overcome by good service, which included, as an absolute essential of modern successful business, persistent and consistent publicity. The task of the "B.C.G.A." was to ascertain all the facts about all the ways in which gas could best serve the community to its advantage, and then to make known these facts both to the industry and to the community it existed to serve. He specially appealed for

the fullest support of the gas exhibit at Wembley. It had been decided to continue the exhibit; and the fact that the Glasgow and Greenock Corporations were whole-heartedly joining the enterprise was a good and hopeful augury. They must keep gas prominently in the public eye, especially in these days when electricity was claiming to be a panacea for all ills. There must be co-operation on the part of the industry, and that could be manifested in no better way than by universal support of the Wembley Exhibit.

GAS SUPPLY AND COAL ECONOMY.

Mr. J. W. Napier, of Alloa, thereafter read a paper on "Gas Supply and Coal Economy," in the course of which he said it can be proved that the gas industry in its treatment of coal to produce, first a gaseous fuel, secondly coke as a solid fuel, and in addition the many bye-products, has advanced further than—and, indeed, is a long way ahead of—any other industry of to-day in the scientific treatment of coal. This fact must be insisted upon, and the public should realize what is undoubtedly true. Especially is this the case when it can be authoritatively stated that gas-works have during recent years made substantial further economies by improved processes of gas manufacture. It is undeniable that the high-efficiency operation of gas-works to-day, which has been reached by scientific research, has altered the whole question of fuel economy, and placed the matter upon a realized basis of practical success. It is not possible to conceive the displacement of the use of gas for domestic and industrial service by any other present-day form of heat energy.

Passing on, Mr. Napier expressed the opinion that, as a domestic fuel, coke has not gained the popularity it well deserves. To be satisfactory for household use, it should contain the minimum ash. In order to increase its use for domestic hot water supply, good quality coke should be supplied, clean, having little ash, and fairly free from water. Gas undertakings ought to cater more for this outlet of a smokeless fuel from gas-works, by supplying coke of good appearance and quality. By increasing the use of coke to the multitude of households, the gas industry will be contributing to coal economy and towards smokeless towns. It is to be regretted that quite a large proportion of coke produced in gas-works requires to be exported to other countries in order to find a market. This should not be so, as it is keenly felt by the gas industry that home industries and domestic uses should easily absorb the full quantity produced. It does appear as if more publicity is required in setting before the public the advantages of the use of coke.

It appears to him that the greatest asset provided by the distillation of coal in gas-works is the tar, which is the basic element of so many products necessary for a large number of processes in industry. Coal tar from gas-works and its products may be said to provide a national security for many industries, and to add enormously to the national activities in the employment of capital and labour. The internal resources of much of the wealth of this country will depend upon such factors as the distillation of coal in gas-works on scientific lines. The gas industry of Great Britain carbonizes about 17 million tons of coal per annum, producing approximately 170 million gallons of crude tar.

It is usually accepted that for intermittent use gas fires are economical. Let us examine the cost and conditions of use of gas and coal fires. With household coal of good quality at 40s. per ton, gas at 8d. per therm of 450 B.Th.U. (3s. per 1000 c.ft.), the heating costs are: Coal 1, gas 5. Correcting for efficiency with coal fires at about 30 p.ct. and gas fires about 60 p.ct., in order to produce an equal amount of heat gas will be 2½ times the cost of coal. Any mere financial comparison will unduly favour the coal fire. It is solid fuel *v.* gaseous fuel; and the latter is not dirty, has no ash to be removed, saves time, is a product of coal conservation, and does not foul the atmosphere. Suppliers of gas are able to put into the households of the country, in the form of heat, six times as large a proportion as electricity of the heat value that is in the coal which has been used to generate the gas or electricity. Electricity, even if the highest hopes of efficiency are realized, can supply only one-fourth the quantity of heat that gas is able to do.

It is desirable to put on record statistics proving the steady advance of the use of gas. From official returns, it is found that for the year 1912 the quantity of gas manufactured in Scotland was 17,301 million c.ft. During the succeeding period of twelve years ending 1924, the quantity had increased to 25,188 million c.ft. The increase is, therefore, 45½ p.ct. This increase has undoubtedly been largely obtained as the result of extended use for domestic cooking and heating, and also for industrial processes.

In discussing economy in the use of coal, it will be well to examine briefly what gas-works as industrial undertakings and large users of coal have succeeded in accomplishing. Steady progress in output of gas has been marked with progress in actually reducing, by means of new processes, the amount of coal needed to make the largely additional quantity of gas required. The actual saving of coal is remarkable. This has been brought about by two instruments, the vertical retort and the Gas Regulation Act. Before the use of vertical retorts, the quantity of gas obtained from each ton of coal was round about 10,000 c.ft. With the vertical retort, the quantity is not less than 15,000 c.ft.; and many works can show much higher yields.

A few examples will illustrate the importance and extent of the economy attained in the conservation of coal by gas-works. In the up-to-date gas-works, instead of, as formerly, 1000 tons of coal being consumed to produce a given quantity of gas, the improved retorts require only 666 tons. In the case of the Greenock Gas-Works, where the new system of retorts has been established for several years, the saving of coal per annum is not less than 21,000 tons, compared with the former process of gas making. Taking Scotland as a whole, as already stated, the increase in the quantity of gas produced is equal to 45½ p.ct. in twelve years. From a calculation, the remarkable estimate is obtained that to produce the gas required in 1924 actually less coal was used than in 1912. The figures are: Coal used for gas production in 1912, 1,730,000 tons; and in 1924 (with a 45½ p.ct. increase of gas required), 1,679,000 tons.

Discussion.

Mr. George Keillor (Greenock) said he was much in agreement with the paper. He was fully convinced that the general adoption of the process of gas manufacture was the only reasonable way of conserving the coal resources of the nation. Another aspect of the question which might be touched on was the importance of having a plentiful supply of the bye-products of gas-making—particularly tar and ammonia. He differed from Mr. Napier when the latter gave the efficiency of the coal fire at 30 p.ct. His opinion was that the figure ought to be 20 p.ct. Of course, he supposed they were all ready to concede that the efficiency of the old-fashioned kitchen range was very much less even than that—probably about one-half.

Mr. H. H. Gracie (Edinburgh) remarked that he was absolutely in sympathy with the views expounded by Mr. Napier in his paper. They were indebted to the author for bringing out the details he had done relative to the amount of coal now used in gas-making as compared with twelve years ago. It was important that the public should learn that 45 p.ct. more gas was now being manufactured in Scotland from a smaller quantity of coal than before. An argument of this nature showed the value of the industry in regard to the conservation of coal.

Mr. David Fulton (Helensburgh) said he did not subscribe to the opinion, sometimes too freely ventilated, that gas was "the real thing" now, and that it had no serious competitor or rival. He held that, while perhaps possibly the industry had done well in the past, it had still got to do much better, because the possibilities and potentialities of its competitors were enormous.

Mr. Mason remarked that, on the question of comparative efficiencies, he had that day been shown a most valuable statement applicable to Greenock. It was well that the statement should be published for the information of consumers, and perhaps Mr. Keillor would supply the particulars.

Mr. Keillor said that they heard so much about the difference in the costs of gas and electricity that in Greenock they had compiled some statistics for the use of the maintenance staff. The statement might be described as a comparison of cost for delivering equal amounts of useful heat for various purposes by gas and electricity. The data had been got together on the basis of gas with a calorific value of 410 B.Th.U. at 7d. per therm, and electricity at 1¾d. per Board of Trade unit.

Electric Radiator.—One pennyworth of electricity (crediting radiator with 100 p.ct. efficiency) will give out 2736 B.Th.U. of useful heat.

Gas Fire.—2736 B.Th.U. of useful heat (gas fire efficiency of 70 p.ct.) costs 0·28d.

Electric Geyser.—Five pennyworth of electricity (geyser efficiency 90 p.ct.) will give 15,390 B.Th.U. of useful heat.

Gas Geyser.—15,390 B.Th.U. of useful heat (geyser efficiency 80 p.ct.) costs 1·34d.

Electric Boiling Rings.—One pennyworth of electricity (boiling ring efficiency of 50 p.ct.) will give 1368 B.Th.U. of useful heat.

Gas Ring.—1368 B.Th.U. of useful heat (gas ring efficiency of 50 p.ct.) costs 0·192d.

The main facts emerging from the comparison were:

(1) Heating rooms by electricity requires the consumption of 4 times as much coal as the same service by gas.
(2) Geysers heated by electricity require the consumption of 5½ times as much coal as the same service by gas.
(3) Boiling water by electricity requires the consumption of 6¼ times as much coal as the same service by gas.
(4) Heating ovens by electricity requires the consumption of 3 times as much coal as the same service by gas.

Luncheon.

The delegates were entertained to luncheon in the saloon of the Town Hall; the hosts being the members of the Greenock Gas Committee. Bailie Millar again presided. The toast of "The Greenock Gas Department" was proposed by Bailie Hunter, of Perth, who paid a high tribute to Mr. Keillor, describing him as one of the foremost gas managers in Scotland. He remarked that the Perth gas undertaking had been put on the right lines by what a deputation learned on a visit to Greenock. Greenock had all along taken, and was still taking, a very prominent part in the development of the gas industry throughout Scotland. They must not forget that it was owing to the initiative and enterprise of Mr. Keillor and his Committee that Greenock was the first Corporation to adopt the Gas Regulation Act. A successful gas manager had to be a scientist, an engineer, and a chemist, besides being a good merchant, and these qualities were to be found in Mr. Keillor. The Chairman, in acknowledgment, said the flourish-

ing position in which the Greenock Gas Department found itself to-day was largely due to his predecessor ex-Bailie John Paterson. The toast of "The Press" was proposed by Mr. W. M. Mason.

ATMOSPHERIC POLLUTION REMEDY.

At the afternoon session papers were read by Mr. J. H. G. Whiteford, B.A., M.B., C.M., Medical Officer of Health, Greenock, on the subject of "Atmospheric Pollution in Relation to Health," and by Mr. George Keillor, on "The Contribution of the Gas Industry towards Reducing Atmospheric Pollution."

Dr. Whiteford said that anything which will prevent the free access of light must be prejudicial to proper and healthy development of the human being; and besides the effect of restricting the growth and development of the tissues, the absence of sunlight has a further vital influence on health—for sunlight has a most powerful destructive action on disease germs. Again, the appearance of the walls of an air cell in a section of a lung of a person living in the slums of an industrial area bears marked evidence of carbon deposit, which must have a strong relationship to the absence of perfect health, as well as to the great prevalence of tubercular disease of the lungs. On what other basis can one explain why the mortality rate from lung diseases, under one year of age, is 14 in the country districts of England, 15·5 in the country districts of Scotland, and 35 in the boroughs? The cost to a community in an industrial area for washing clothing, curtains, &c., as compared with the washing costs in a typical health resort with comparatively slight smoke, is greatly increased; and it has been calculated that this increase amounts to 7½d. weekly per household.

Mr. Keillor, in the course of his paper, said that if all coal at present consumed in the raw state were scientifically treated as in the process of gas making, it would provide:

1. Enough heavy oil for generating power to drive our naval and merchant ships—without importing a gallon.
2. —Enough smokeless fuel and gas to heat all our buildings and run our factories at a low cost, and without the production of smoke.
3. —Enough benzole for all our motor traction requirements.
4. —Sufficient sulphate of ammonia to fertilize the land, with a good surplus for export.
5. —An increased production of food, owing to ample and cheap fertilization of the land.
6. —Enough fuel oil and gas to ensure ample, cheap power.
7. —A clean and healthy atmosphere for our large towns.

There is an old Italian proverb which reads: "All diseases come in the dark and are cured in the sun." We are spending money in this country in vast amounts in enlarging our hospitals, our sanatoria, and our cemeteries, that should be spent in enlarging our gas-works.

At the present time the gas-works of the country produce about 9 million tons of coke annually, but this valuable smokeless fuel is too little used domestically. If gas-works coke was employed more freely for domestic heating, the price would be less liable to fluctuate; and as this is still the most valuable credit in the process of gas manufacture, its ready sale as a domestic fuel would be reflected in the price charged for gas. While the thermal efficiency of the best type of gas-heated boiler has now reached 75 p.ct., the running cost, if any considerable volume of water was required, would exceed that of the coke-heated boiler, and its use under those conditions would usually be confined to providing an auxiliary supply. All gas undertakings should therefore place the economy and advantages of the coke-fired boiler prominently before the public, and encourage its sale as far as possible.

For all rooms in occasional or intermittent use, gas fires are not only more convenient but cost less than coal fires; while for bedrooms they are invaluable. Taking the price of gas at 7½d. per therm (410 B.Th.U. gas) a modern gas fire with seven radiants consuming 4 c.ft. per radiant will cost slightly less than 1d. per hour. So that in Greenock, at all events, a gas fire burning continuously for five hours is cheaper than a coal fire.

The Housing Committee of the Greenock Corporation early recognized the advantages of gas in the home; and they are to be heartily congratulated upon their wisdom in providing each house with a gas cooker or a grill, a gas wash-boiler, and one or two gas fires, depending upon the size and location of the houses. All houses, however, independent of size or the ability of the householder to pay, are equipped with electric light; and we are giving away no secret when we say that many of the tenants would prefer to light their homes with gas.

The contribution of the local Gas Department and its customers towards the abatement of the smoke nuisance has been considerable. There are 17,849 gas consumers in Greenock; and among them there are on free loan no fewer than 16,326 cookers, hotplates, and rings. Of course, there are also a number of private appliances in use; and inclusive of the fires in the State-aided housing schemes, 668 gas fires have been fixed since March, 1924. Invaluable assistance has been given by the Master Plumbers and Gasfitters' Association in advancing the cause which we all have so much at heart.

The output of gas in Greenock will this year exceed 600 million c.ft., equal to 2,501,000 therms, compared with 418⅔ million c.ft. in 1913-14 (an increase of 43⅓ p.ct.); and it is estimated that 75 p.ct. of the total output is used for domestic purposes.

The price of gas in Greenock to ordinary meter consumers is 7½d. per therm, equal to 2s. 6¾d. per 1000 c.ft., compared with 2s. 6d. per 1000 c.ft. in 1913-14.

What we are doing in Greenock to dispel smoke from the chimney-tops is just what every gas undertaking in the country is doing; and our united endeavours are already influencing the state of the atmosphere. Fogs are now fewer; sunshine has increased; and the death-rate from diseases affected by smoke has fallen. But there are still some 35 million tons of coal used raw each year for domestic consumption alone; and until this economic and hygienic folly ceases, the toll which smoke takes of life and health will of necessity go on.

Discussion.

Ex-Bailie Lemmon (Greenock) said the Smoke Abatement Committee of the Greenock Corporation had in bygone years been subjected to a good deal of ridicule because of their supposed inaction. His own view was that on this question of atmospheric pollution by smoke there ought to be set-up throughout the whole country something in the nature of a time limit. If at the end of the period fixed there had not been a general abatement of the nuisance, the offenders ought to be called upon to face the consequences. Everybody knew that the countryside would be the better without black smoke; and it did seem to him that the people who created the nuisance should do their best to find a remedy for it.

Bailie Isabelle Kerr wished that more women had been among the audience to hear what had been said. Speaking as a woman, she personally deprecated the great wastage that had gone on for so many years in the use of coal for domestic purposes in kitchen ranges. It was dreadful to reflect that so much work, energy, time, and money should be expended, when the food could be as easily and much more economically prepared by using gas cookers. If every man and woman, and the proprietors of large works, would concentrate on facing the problem of smoke abatement, it would soon be solved.

Mr. Whysall (Electrical Engineer, Greenock) said that, in his opinion, electricity was one of the best preventives for atmospheric pollution. Anyone who was at all observant in his journeyings through the industrial parts of the town was bound to note the great change that had taken place. Speaking as an individual, he was absolutely at one with Mr. Keillor in what he maintained for the Gas Department. He favoured legislation in smoke abatement, but prophesied that it would take twenty years to come to pass. He would like to see such good progress made by electricity that the gas engineers would have to look still better after their consumers in regard to the needs of domestic life.

Bailie Hunter (Perth) said he had been delighted to hear the observations of Bailie Isabelle Kerr, and felt he must congratulate the people of Greenock upon having a lady of her outstanding talent and ability in the Town Council. Experience was showing that the owners of factories were realizing more and more that it did not pay them to send great quantities of smoke into the atmosphere. The same knowledge, unfortunately, was not so prevalent among housewives. He had been impressed by one suggestion put forward by Mr. Keillor, which was that coke should be sold in small quantities. In Perth they had tried to encourage the sale of coke among the poorer people, and had been fairly successful in creating a healthy demand in this way.

Ex-Bailie Paterson (Greenock), speaking as an old Convener of the Gas Committee, said he was bound to confess that the Greenock Corporation, during his régime, had been most generous. It seemed to him that they had been pioneers of smoke abatement in Greenock.

Mr. James Bell (Dumbarton) remarked that, in spite of the inefficient and ineffective legislation relative to smoke abatement, improvements had been going on in this direction. Such improvement as had been noted was due to the wise policy adopted by the gas industry generally, in pushing the use of gas appliances. He had the feeling, however, that they would look in vain—at least for many years to come—for any legislation which was going to do away entirely with the evil of atmospheric pollution; and this being the situation, it behoved all interested in this pressing problem to do the best they possibly could to extend the use of gas.

Mr. Gavin M'Arthur (Cleansing Superintendent Greenock) said that, though he was not in any way connected with the gas industry, he felt bound to admit that Mr. Keillor had put forward a strong and convincing case for the greater use of gas. He put in a special plea for the general home combustion of domestic refuse. In attaining this end, he believed the gas industry was capable of proving a helpful ally.

The proceedings terminated with the usual votes of thanks—proposed by Mr. Mason.

Dr. Saleeby's Lecture.

In the Watt Hall, during the evening, Dr. C. W. Saleeby delivered his suggestive and reasoned lecture on the smoke peril and its effect on national life.

A Kent Invitation.—The Secretary of the Kent Section of the Southern District Salesmen's Circle informs us that the concluding meeting of the session will be held at Tunbridge Wells, at 3 o'clock, on Thursday, the 23rd inst., and that the members would heartily welcome the presence of some of the senior officers in the district.

MICHELL CRANKLESS GAS ENGINE AND COMPRESSOR.

Most gas undertakings in the course of their development are confronted from time to time with the difficulty that trunk mains which were laid down years ago are not of sufficient capacity at the usual low pressures available to cope with the continual growth of the cities and the ever-increasing demand for gas, particularly at the times of peak loads. To meet these conditions, the use of "boosting" or compressing plant is resorted to, in order to avoid the high cost of replacement of, or extensive addition to, the trunk mains. In the general acceptance of the term, the function of the boosting plant is to increase the pressure in the mains available from the holder, by taking the gas at the holder pressure and passing it onward at an increased pressure of several inches water-gauge direct into the low-pressure mains. The function of the compressor is to take the gas at the pressure as delivered from the holder, and drive it forward at an increased pressure of several pounds per square inch through independent high-pressure mains for delivery either into a holder in the district, far removed from the manufacturing station, or for discharge, through suitable governors, into the low-pressure reticulation some distance from the works. Machines for either of the above purposes must be reliable and efficient in operation, and must operate satisfactorily within a wide range of delivery. The driving force for the plant should preferably be derived from the gas available in the mains; as by this means the use of an outside power service is avoided, particularly in the case where the plant is placed at a point away from the gas-works.

Machines of various types have been employed as boosters, but, the volumes of gas being large and the pressures to be generated comparatively low, they have hitherto in most instances been either of the centrifugal fan class, or of one of what are known as the "positive rotary" types of blower machines embodying rotating blades or impellers. The pressure requirements of the plant may vary from a few inches water-gauge in the former case to (say) five or ten pounds per square inch in the latter case; the tendency being to increase the pressure considerably above these figures. For high pressures, the use of reciprocating machines of the familiar piston-cylinder class is often resorted to. The plant which is the subject of this article is of this type, but it will be seen that in the particular design developed it is capable of handling large volumes of gas at comparatively low, as well as at higher, pressures in a very efficient manner.

We illustrate (fig. 1) a new type gas booster unit of the latter class, constructed by Messrs. Crankless Engines, Ltd., of Melbourne. This unit consists (as can be seen) of two machines arranged on a common bedplate, and directly coupled together by a clutch coupling. The booster is the right-hand member of the unit, and comprises eight double-acting cylinders each of $9\frac{3}{8}$ in. diameter and $8\frac{1}{2}$ in. stroke. The cylinders are arranged in four pairs around the axis. The two pistons of each pair are connected by a central "yoke," carrying the articulated slippers by which the double piston is actuated from the driving slant, according to the Michell crankless construction. The slant, which is keyed to the shaft of the machine, revolves at 750 r.p.m.; the rated output of the booster being 200,000 c.ft. per hour, delivered against a pressure equal to 60 in. of water. The delivery main for the gas is 18 in. in diameter, and is seen in dotted line emerging from the bedplate beneath the booster.

The characteristic of this type of machine which especially commends it as a low-pressure blower is its high volumetric capacity relatively to its bulk. High volumetric capacity is commonly regarded as the special attribute of turbine machinery, but reciprocating blowers of the crankless type can easily be designed to deliver greater volumes of compressed air or gas than turbine blowers of equal dimensions and much higher rotary speed. The booster illustrated discharges at full load a volume of gas approximately equal to 130 times its own total bulk per minute. It is at the same time as well balanced dynamically as a turbine, and is more efficient as a compressor, especially under varying loads, than a turbo-machine. Its volumetric efficiency, determined both from indicator diagrams and by orifice and pitot-tube measurements, is 96 p.ct.

The intake of gas to the booster is controlled by rotary valves, which are directly driven by the shaft, but rotate on independent ball-bearings. The delivery valves are light automatic spring valves; the machine being thus adapted to work efficiently with varying delivery pressures, as it is usually required to do in practice.

The booster is driven by the machine which forms the left hand member of the unit as illustrated; this being a Michell crankless gas engine having eight cylinders arranged in much the same way as the cylinders of the booster, but in this case single-acting. The cylinders are of $4\frac{3}{4}$ in. bore and $5\frac{3}{8}$ in. stroke; the rated power of the engine being 50 H.P. at 750 r.p.m. when supplied with gas of 500 B.Th.U. (net) per c.ft.

The valve-shafts of the engine drive two oil pumps located in the box-shaped bedplate that is to be seen; this bedplate serving also to contain the tank and filter for the lubricating oil, and comprising intake and delivery chambers for the gas pumped by the booster. Each pump, one of which serves for the lubrication of the engine and the other for the booster, supplies eight distinct points with oil, each being a small Michell crankless pump with eight single-acting plungers. To be seen beneath the engine is a system of switch-valves by means of which the pressure at which the oil is delivered to any one of the lubricating points can be read on one or other of two pressure gauges. Ignition is effected by high-tension

magneto; a special starting magneto being fitted to provide an effective spark when the engine is turned over slowly by hand, as can easily be done by one man. This high-speed compressor, however, lends itself equally well to direct electric drive or high-speed steam engine or turbine, in cases where electric or steam drive is more desirable.

The plant described and illustrated in the present article is the second of two similar units which have been supplied to the Australian Gaslight Company. Before dispatch from the works of the makers, Messrs. Crankless Engines, Ltd., of Melbourne (whose London Office is at Aldwych House, W.C.), each unit was submitted to thorough tests. It will be readily understood that, as the flow of gas in a "boosted" main is entirely dependent on the continuity of action of the booster, the non-stop capabilities and durability of the latter are its most important features in the eyes of the gas engineer.

The principal results of the tests referred to are given in diagram form in fig. 2. In these tests the booster delivered not coal gas, but air supplied to the intake at mean atmospheric pressure and temperature of approximately 29·8 in. Hg. and 60° Fahr. respectively. Under this condition the frictional resistance in the valves and other passages of the booster was, of course, much greater than when pumping coal gas. The diagram of fig. 2 shows, in addition to the results of the tests of the complete unit, indicator and brake tests of the engine running uncoupled, and also coupled to a Froude hydraulic dynamometer. The various tests agreed in showing that the mechanical efficiencies of the engine and booster are each approximately 87 p.ct. over a considerable range of load; the volumetric efficiency of the booster being not less than 96 p.ct. at all loads up to the maximum. The gas consumption of the engine was slightly more than 0·5 p.ct. of the volume of air pumped. When pumping gas at the same pressure, the corresponding consumption would be appreciably below 0·5 p.ct.

A point of much interest in this particular design of plant is that it can operate efficiently within a wide range of delivering capacity simply by variation of the speed of the engine.

In the apparatus referred to, the control is by hand, but the plant could be suitably controlled by automatic means; the speed of the engine and compressor being varied to maintain a constant pressure in the delivering main. Owing to the number of pistons in operation, and the frequency of their movements, pulsation in the delivery pressure is almost eliminated. The two machines installed in Sydney are working satisfactorily; and a repeat order comprising three similar machines is now being executed. In addition, a machine with a capacity of 150,000 c.ft. per hour at a pressure of 5 lbs. per sq. in. is being manufactured for the South Australian Gas Company, of Adelaide.

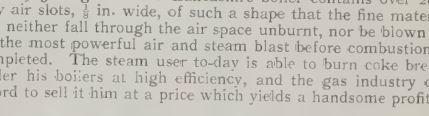
The inventor of the crankless engine—Mr. A. G. M. Michell—will be immediately recognized by many of our readers as the inventor of the world-famed thrust bearing, which has made possible the construction of the large battleships (of which H.M.S. "Hood" is an example), and which is now incorporated in all modern ships whether for the Royal Navy or for the Merchant Services. It should be added that the crankless principle is applicable to engines of all classes, and is regarded by many of the highest authorities as an invention which will revolutionize engine construction within the next few years. The sole rights for the manufacture of the crankless gas compressor in Great Britain have been secured by Messrs. George Waller & Son, Ltd., of Stroud.

COKE BREEZE FOR STEAM GENERATION.

Tests on the "Turbine" Furnace.

The adoption of improved methods in the gas process from the point of view of over-all thermal efficiency will have the effect of releasing more and more coke breeze for sale. This is particularly the case when steam is generated by waste heat. At the same time much more efficient apparatus for burning coke breeze under gas-works boilers is now available.

In this connection the "Turbine" forced-draught steam-jet furnace is of particular value, being specially adapted for burning coke breeze and dust. The general design of the furnace is already familiar; and it will be remembered that an ordinary 6 ft. by 3 ft. grate for a Lancashire boiler contains over 2000 tiny air slots, $\frac{3}{8}$ in. wide, of such a shape that the fine material can neither fall through the air space unburnt, nor be blown off by the most powerful air and steam blast before combustion is completed. The steam user to-day is able to burn coke breeze under his boilers at high efficiency, and the gas industry can afford to sell it him at a price which yields a handsome profit.



Sectional Elevation of "Turbine" Furnace.

It is the object of this article to give some authentic figures as to the results being obtained with the "Turbine" furnace using coke breeze only; though in a general way the ordinary steam user is well satisfied with a mixture of coke breeze and coal, which gives no more trouble than does coal alone.

The first typical test, which lasted eight hours, is that carried

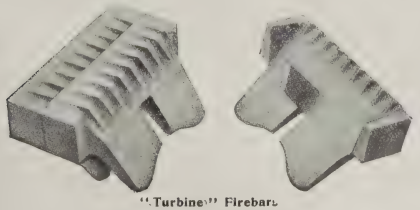
out some time ago at the Beckton Works of the Gas Light and Coke Company, using a "Lancashire" boiler 30 ft. by 8 ft.:

FUEL—	
Coke breeze, 60 p.ct. under ½ in.	
Total consumed	8400 lbs.
Average per hour	1050 lbs.
Average per sq. ft. grate area per hour	38·2 lbs.
ASH—	
Total	14 cwt.
P.ct.	18·7
WATER—	
Total evaporated	4000 gallons.
Average per hour	500 gallons.
AVERAGES—	
Feed temperature	53° Fahr.
Pressure	66 lbs. per sq. in.
Jet pressure	60 ,, ,, ,, ,,
RESULTS—	
Lbs. water per lb. fuel as fired	4·77
,, ,, ,, ,, ,, from and at 212° F.	5·7
FLUE GASES—	
L.H. side, CO_2 = 17·4 p.ct., O_2 = 2·9 p.ct., CO = 0·6 p.ct.	
R.H. side, ,, = 16·7 ,, ,, = 3·5 ,, ,, = 0·5 ,,	
Average, ,, = 17·0 ,, ,, = 3·2 ,, ,, = 0·55 ,,	

The second test was at the Tinsley Park Collieries, Ltd., of Sheffield, using metallurgical coke breeze dust:

NAME OF SAMPLE	"Coke Ash"
ANALYSIS OF FUEL as Received—	P.Ct.
Volatile matter	12·32
Ash	21·92
Fixed carbon	52·22
Free moisture	12·01
Hygroscopic moisture	1·53
Calorific value	9381 B.Th.U.
BOILER—	
30 ft. by 8 ft. 6 in. "Lancashire" and economizer. Fitted with "Turbine" furnace, 33 sq. ft. grate. Evaporation guaranteed 700 gallons per hour. Duration of test, 5 hours.	
FUEL—	
Total consumed	9550 lbs.
Average per hour	1910 ,,
Average per hour per sq. ft. grate	58 ,,
WATER—	
Total evaporated corrected to 60° Fahr.	4223 gallons
Average per hour corrected to 60° Fahr.	845 ,,
AVERAGES—	
Steam pressure, gauge	101·5 lbs.
Jet pressure	90 ,,
Feed temperature	227° Fahr.
RESULTS—	
Lbs. water per lb. fuel as fired	4·42
Lbs. water per lb. fuel from and at 212° Fahr.	4·55

Obviously, therefore, if coke breeze alone will give results of this character, when mixed with coal the question is simplified. If a coal containing 25 to 35 p.ct. of volatile matter is mixed with coke breeze so as to bring the volatile content of the product down to (say) 12 to 15 p.ct., this results in a much higher efficiency under ordinary conditions of steam generation—a fact which is not generally realized, but which in practice is of the greatest importance, especially from the point of view of selling coke breeze. This has been determined by a series of detailed tests recently carried out on a large "Cochran" boiler



"Turbine" Firebar.

equipped with a "Turbine" furnace. Under elaborate test conditions, using feed-water almost at boiling-point, a given quality of high-grade washed coal showed an evaporation of 10·2 lbs. of water per lb. of coal, whereas coke breeze gave 7·3 lbs.; the firing and attention in each case being of the best character. When the coke breeze was mixed with the coal, however, the figure for the product was found to be much above that calculated. Thus, for example, in one series of tests with three parts of coke breeze to two parts of coal the result was 10·7 lbs. of water per lb. of mixed fuel, instead of about 8·5 lbs., as might have been expected. The reason is that the increase in the fixed carbon content, and the corresponding improvement in the radiant heat emission mean a great reduction in the escape of unburnt or partially burnt volatile matter, which cannot be prevented with the use of raw coal. In many cases the results are astonishing, especially in small boiler plants not equipped with economizers.

Coke-Oven Managers' Association (Midland Section).—On April 16, at 2.30, a meeting will be held at the University of Sheffield, when a lecture on "The Combustibility and Reactivity of Coke" will be given by Prof. R. V. Wheeler. On June 11, a visit will be made to the Barugh plant of Low-Temperature Carbonization, Ltd.; and on July 9 the works of Messrs. Stainby and Lyon, Ltd., of Knottingley, will be visited.

MIDLAND JUNIOR GAS ASSOCIATION.

The Annual Meeting of the Association was held at the Council House, Birmingham, on Friday, March 27—Mr. HARRY CLARK presiding.

THE RECOVERY OF WASTE HEAT FROM FURNACES.

By WILLIAM NEWTON BOOTH, B.Sc., A.M.Inst.C.E.

When I was asked by your Secretary to prepare a paper, I chose a subject which had been occupying my attention for some time and one in which industry in general was interested, unaware that only a few days before the paper was to be presented you were to listen to a discourse on waste-heat boilers by a member of the staff of a firm who are doing a great deal of work in this direction. In spite of this, I trust that I shall have something interesting to say to you, and be able to show that, useful as waste-heat boilers are, they are not necessarily the complete and final answer to all waste-heat problems.

It is now recognized as an industrial axiom that waste of any kind must be stopped, if we are to compete with our products in the world's markets; and the annals of our industrial progress during the last century record many instances of the recovery and use of so-called waste products. Not least among these is the tremendous development which has taken place in the use of coal tar. Far from being considered a waste product, it now figures largely on the revenue account of all coal carbonization processes. While I do not pretend that the utilization of otherwise waste heat will have such far-reaching and important effects, yet it cannot be denied that the cost of heating in nearly every branch of industry is far from being a negligible item in the expenditure account; and in many industries—*e.g.*, iron and steel—it is the principal item. Moreover, the thermal efficiencies of the processes in use are often very low indeed, and in nearly every case leave much room for improvement. If also we remember that our fuel reserve supply is a constantly diminishing quantity, there is every reason for giving most careful attention to the conservation of fuel; and the recovery of waste heat is the first step in this direction.

WASTE HEAT FROM FURNACES.

Let us inquire into the nature of waste heat in connection with the operation of furnaces. In all such appliances fuel is burnt in oxygen (usually obtained direct from the atmosphere, accompanied by four times its volume of nitrogen), and the resulting flame consists of various gases heated to a high temperature. In the furnace these gases are required to give up their heat in a chamber at a relatively high temperature, and must consequently leave that chamber at a temperature somewhat above this, and carry away as sensible heat a more or less large proportion of the heat of the original fuel. This rejection of heat in the spent gases is inherent in all appliances or processes where heat is generated in, and carried by, a material fluid. In all such cases the availability for use of the heat present is a question of the temperature changes through which the heated fluid can be taken; and it is inevitable that some should be rejected. It is principally this question of the effect of temperature on the availability of heat which makes the heat engine such a relatively inefficient machine; very large quantities of heat—generally, however, at a low temperature—being necessarily discharged in the exhaust. Were it not for this inherent low efficiency of the heat engine, there is little doubt that fuel furnaces would be entirely replaced by electric furnaces for anything but quite low temperature work, because, with electrical heating, no heated material fluid need necessarily leave the hot chamber. However, the high-efficiency heat engine being an impossibility, fuel furnaces will continue to be used; and it behoves us as engineers to improve them in design, operation, and thermal efficiency.

When any fuel is burnt, the combustion gives rise to a perfectly definite amount of heat which is expended in raising the temperature of the flame gases. It will be manifest that, if the fuel is incompletely consumed, only that portion which is actually burnt in the combustion can be reckoned; and if an excess of air or oxygen is used, this can take no part in the actual combustion, but will merely add to the quantity of gases to be heated. The highest temperature is therefore reached when perfect combustion is obtained without any excess of air, and the temperature will be markedly less if such exact regulation of the air is not secured. The quantity of heat which can be given up by the flame gases in the heating chamber is clearly the product of their quantity, mean specific heat, and the difference in temperature between the flame gases and the waste flue gases—*i.e.*, the efficiency of heat transmission in the heating chamber cannot exceed the fraction

$$\frac{\text{theoretical flame-gas temperature} - \text{flue-gas temperature}}{\text{theoretical flame-gas temperature.}}$$

If this efficiency is to be increased, we must do one of two things—either increase the flame temperature or decrease the flue temperature. The latter is governed by the heat of the chamber itself, usually fixed by the conditions of the process; and apart from arranging ports and flues so as to give adequate circulation of the flame gases, comparatively little can be done

in this direction. We must therefore look towards increase in flame temperature as the best solution. This can be done in two ways:

(i) By careful regulation of the air for combustion.
(ii) By preheating as far as possible the air and/or fuel.

Fig. 1 shows the proportion of the calorific value of average coal gas fuel available for transfer in heating chambers at various temperatures and for different regulations of the air supply, but no preheat. The importance of correct regulation of air supply is apparent.

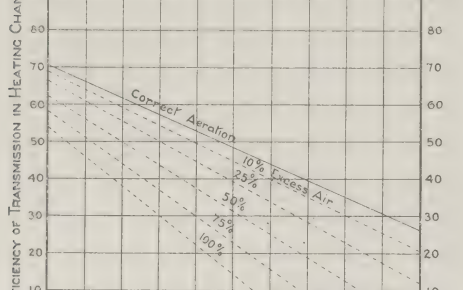


Fig. 1.—Maximum Efficiency of Heat Transmission.

It is manifestly foolish to attempt improvement by the addition of apparatus for preheating until everything possible has been done by fuel and air regulation. Fig. 2 shows the effect of preheat, assuming theoretically perfect regulation of air supply.

Fig. 2.—Maximum Efficiency of Heat Transmission.

The effect of preheating on the chamber efficiency of high-temperature furnaces will be seen to be very great.

It is important to reduce the loss of heat through the walls of the heating chamber, as any reduction effected here has a double effect—*i.e.*, in the chamber and in the flue. Careful wall construction can do much in this direction. The use of materials of low conductivity is becoming more and more common, and composite walls (an inner refractory lining to withstand high temperatures, and a backing of insulating material) are now usual features of furnace design. Fig. 3 shows the actual values of the losses which may be expected from such walls of various thicknesses. If, however, in addition to careful wall construction, the heat loss which must inevitably take place through the outer walls can be taken from the flue gases instead of from the chamber gases, an additional saving will be effected, as such transfer can take place without necessitating additional gases to pass through the heating chamber. It is not always possible to make this arrangement; but in many cases it may be done by constructing the primary waste gas flues so as more or less completely to surround the heating chamber proper.

Let us now pass on to the waste gases. It is manifest that those which leave the furnace chamber by leakage are lost to all practical purposes, and with them their sensible heat; and if any waste heat recovery is to be attempted, careful attention must be given to the prevention of such leakages, ensuring that as much as possible of the hot waste gases enters the

flue provided for conducting them to the recovery apparatus. The sensible heat of such waste gases can then be recovered and (*a*) returned to the heating chamber, or (*b*) applied to some external use.

Heat returned to the heating chamber is more efficiently employed than it can possibly be in any external application, as it increases the heat available for transmission in the heating chamber without in any way increasing the heat losses; in fact, in the generality of cases, the quantity of gas leaving the furnace is reduced, and with it the sensible heat contained therein. Consequently, considering the added heat only, the efficiency of its utilization usually exceeds unity—a far better result than can be expected of an external application of the same heat. It is therefore towards returning to the heating chamber the largest possible fraction of the waste heat leaving the same that we must look for the highest efficiency of utiliza-

tion. There are cases where this is not feasible or where there are other sources of heat or the amount of waste heat available is much greater than can be utilized in this way. Thus in many cases there will inevitably be a certain amount of waste heat available for use external to the furnace; but it may be taken as a general thing that it is better to make a furnace self-recovering of its waste heat as far as possible, before attempting to recover waste heat for external uses.

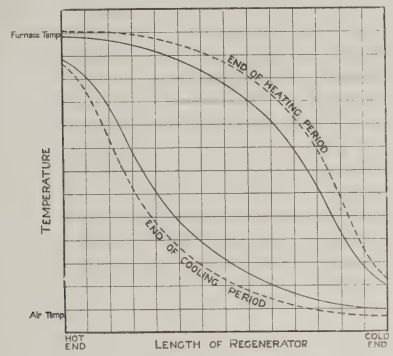

Fig. 5.—Temperature Changes in Regenerator Chequerwork.

A simple arithmetical calculation may make the argument clearer. Let us consider a small gas-fired furnace having 4½-in. walls, the total internal area being (say) 13 sq. ft., working at 1000° C. and consuming 1 therm per hour. Then the flue loss (from the diagram) is 52 p.c. and the wall loss 0·4 therm per hour. The heat balance is, accordingly, as shown in Table I., item 1. Supposing a heat recovery plant in the shape of (say) a steam boiler is attached to the flue, then 10 p.c. of the gross value of the fuel will be lost as latent heat;

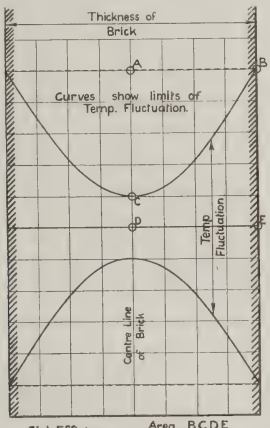

Fig. 6.—Meaning of Slab Efficiency.

and assuming the boiler has an efficiency of (say) 70 p.c., there will be recovered usefully $(0{\cdot}52-0{\cdot}10)\times 0{\cdot}70=0{\cdot}294$ therm, giving a net consumption of 0·706 therm, of which only 0·08, or about 11 p.c., is usefully employed.

If we now improve the wall construction by adding (say) 2 in. of insulating material, we shall reduce the wall loss to one-quarter of its old value—viz., 0·10 therm per hour—and to get the same useful work from the furnace, the consumption will be $0{\cdot}08+0{\cdot}10+\frac{52}{48}\times 0{\cdot}18=0{\cdot}375$ therm, and the net consumption will then be 0·264 therm, as shown at item 2.

If still further improvement is made by fitting a false interior, so that the hottest waste gases encircle the heating chamber on the way to the flue, it is possible to take as much as 60 p.c. of the wall loss from the waste gases. The net wall loss is thus only $0{\cdot}04\times\frac{100}{48}=0{\cdot}25$ therm per hour, and the total fuel consumption $0{\cdot}08+0{\cdot}04\times\frac{100}{48}=0{\cdot}25$ therm per hour; the distribution being as shown at item 3 of the table.

If we now fit a recuperator with an efficiency (on air only) of (say) 75 p.c., we shall get an air temperature of about 540° C., and the flue loss will be correspondingly reduced, with an increased efficiency, as shown at item 4 of the table. With the fitting of a recuperator the temperature head in the furnace chamber will be increased, and it should then be possible to double the output from the furnace. The wall loss would remain the same, and the flue loss would not increase in the proportion of the increase in work. The results to be expected are shown as item 5 of the table.

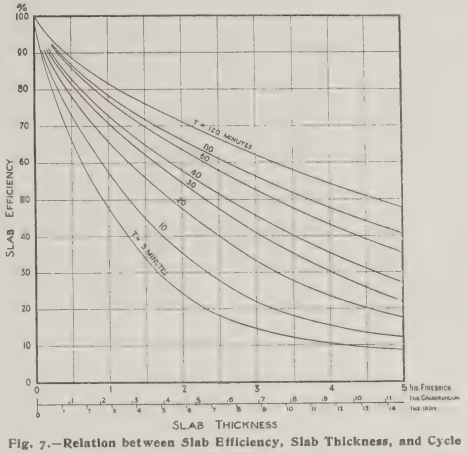

Fig. 7.—Relation between Slab Efficiency, Slab Thickness, and Cycle Periods.

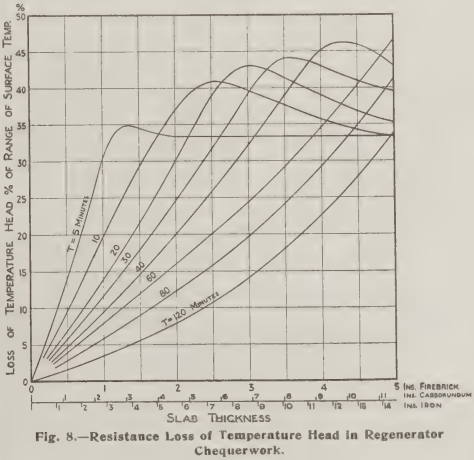

Fig. 8.—Resistance Loss of Temperature Head in Regenerator Chequerwork.

It will be seen that in every case an attempt to use the waste heat in the furnace itself is accompanied by a decrease in net fuel consumption after due credit has been given for the value of any available waste heat; and if we were to continue the process further, a still further decrease would be found.

There are three things going into a furnace heating chamber to which some of the sensible heat of its waste gases can be transferred and carried thereby back into the heating zone. In the order of their effective importance they are:

(i) The work to be heated.
(ii) The air for combustion of the fuel.
(iii) The fuel itself.

Owing to its relatively small volume, and the fact that some of the hydrocarbons suffer thermal decomposition at temperatures above (say) 700° C., it is not always an economic proposition to preheat coal gas. With coal producer gas of the Mond type, however, the thermal capacity of the gas exceeds that of the air, and when preheated to high temperatures, endothermic reactions take place between the constituents of the gas, resulting in an actual increase in its calorific value. In such cases preheating of the gas has a very marked effect. To many furnaces, however, producer gas is delivered hot; and as by no means can it be heated above the temperature of the waste gases by utilizing their waste heat, nor those gases cooled thereby below the temperature at which the fuel gas is supplied, there must necessarily be a balance of waste heat which cannot be utilized in the furnace and is therefore available for use elsewhere.

Recuperators.

In this type working is continuous; the hot waste gases and the gas or air to be heated flowing practically in opposite directions on either side of a solid partition or diaphragm through which the heat is transmitted by conduction. The usual material is fireclay; and much ingenuity has been displayed in designing constructions to overcome the inherent defects of this material. An ideal recuperator should be compact, be capable of high rates of heat transmission with a small temperature loss, and be capable of use for long periods while still remaining gas and air tight. The material should therefore be of high thermal conductivity, non-porous, and of sufficiently high mechanical strength to allow of the use of thin partitions; while the construction should also be such that movements due to differential thermal expansion do not cause undue stress in the material, nor give rise to cracks or broken joints. On all these points fireclay leaves much to be desired.

The use of metal recuperators is now becoming common in low-temperature work—*e.g.*, preheating of air for boiler firing—and the advent of heat-resisting metals such as calorized iron, the chrome steels, and nickel chromium alloys (the latter of which may be made non-scaling at temperatures of over 1000° C.) has made possible the use of metallic partitions in furnace recuperators; and their use will no doubt extend considerably. Owing to the superior strength and thermal conductivity—over fifty times that of firebrick—very high heat transmission can be obtained, and a compact efficient design is possible.

Owing to the stresses set up by differential expansion, it is unwise to work fireclay partitions with a greater temperature difference between the faces than 120° Fahr., corresponding to a heat transmission of about 1200 B.Th.U. per sq. ft. per hour for a 1-in. partition, and proportionately less for thicker partitions; and this, together with the porosity of firebrick, which limits the allowable gas velocity, imposes a very low heat transmission limit in fireclay recuperators. Such considerations, however, do not apply to the metallic type.

Heat Transmission.

When a gas is flowing in a tube or channel, there is always close to the wall of the channel a film, the thickness of which depends upon the gas velocity, which is in streamline motion—*i.e.*, the flow is everywhere parallel to the solid surface. The transmission of heat through such a film is by conduction; and as gases are very poor conductors of heat, this film offers a very great resistance, and a corresponding loss of temperature head. In recuperators, of course, this effect is felt on both sides of the partition. As the thickness of this streamline film gets less when the gas velocity is increased, the resistance to the flow of heat diminishes also; and consequently, with a given temperature difference, much greater heat transmission can be effected when the gas velocity is high than when it is low.

At low velocities the combined resistance of the two streamline films is comparable with the resistance offered by (say) an ordinary thin fireclay partition, so that it may constitute the greater part of the total resistance; and little advantage would then be felt by making the partition thinner, or constructing it of metal. At higher gas velocities, however, the resistance of the partition becomes relatively much more important; and it is then that the advantage of metallic partitions becomes most apparent. Then, owing to the higher rates of heat transmission obtained, it is possible, without loss of efficiency, to reduce the transmitting area to such an extent that, in spite of the higher gas velocity used, only a relatively small increase in pressure head is necessary to force the air through.

It will be clear that the most efficient recuperator is obtained when the gas and air flow are truly counter-current—*i.e.*, the streams on either side of the partition are everywhere in opposite directions. The kind of heat transmission rates to be expected with various gas velocities and for various partitions are shown on fig. 4. Before leaving the subject of recuperators it should be pointed out that these appliances lose heat through their outer walls in exactly the same way as furnace heating

chambers, and such loss should be reduced by decreasing the exposed area and constructing the walls of material of low conductivity. It should never be forgotten that the primary function of a recuperator is to *heat* air or fuel gas, and that the cooling of the waste gas is only secondary and consequential.

The following table gives particulars of the actual performances of some recuperators the author has had occasion to test.

Regenerators.

In this type two chambers are provided, fitted with valves so that the waste gas and air to be heated are passed alternately therethrough; the gas and air flowing in opposite directions. The chambers are filled usually with chequer brickwork which alternately absorbs heat from the hot gases and gives it up again to the air.

The following points arise in connection with the design and operation of regenerators:

(1) Their operation is intermittent, and involves the provision and working of change-over valves. They are therefore not so simple as recuperators, and not so suitable for relatively small installations.

(2) At each reversal the fuel gas or hot air contained in the regenerator at the time is passed direct into the flue, while the cooled waste gas returns to the furnace. Unless care is taken in working out the proportions of the design, this may have a very appreciable effect in reducing thermal efficiency.

(3) The hot regenerator provides a considerable store of heat; and this may be returned to the heating chamber very rapidly, if occasion requires it. For some processes where a very rapid rate of initial heating is required, followed by a period of slower heating or maintaining the work at a high temperature, this property of the regenerator may be used to advantage.

(4) The capacity of the regenerator as compared with the furnace fixes the period which may elapse between reversal of the valves; and this may be varied between relatively wide limits so as to meet the needs of the particular problem under consideration.

(5) The heat capacity of regenerator furnaces is considerable, and consequently they are not so suitable for intermittent working as furnaces having a lower heat capacity.

So far as the author is aware, no complete theory of the heat transmission of a regenerator has yet been worked out. The following factors however affect the design of such apparatus and the calculation of the amount of brickwork necessary in any particular case.

Surface Temperature Changes in Chequerwork.

Fig. 5 shows the progressive temperature changes which take place during the heating-up of a regenerator chamber. It will be seen that at the ends of the chamber the range of temperature is comparatively small, while in the middle it is much greater. The mean temperature range of the surface is as indicated on the figure, and is usually not much more than half the temperature difference between the hot and cold ends. The actual figure in each case may be obtained or worked out from a design, and may be expressed as a factor which the author terms "surface temperature efficiency."

When the surface of a conducting material is subjected to a periodically varying temperature, the range of temperature at internal points in the material becomes steadily less as we recede from the surface, and the phase of the temperature change becomes likewise progressively later. Fig. 6 indicates this effect, showing the temperature of the various portions of the material at the commencement and at the end of the heating period. It will be seen that the heat stored is much less than would be the case if all the material were to go through the same temperature range as the surface, and the ratio of the heat actually stored to that which would be stored under these conditions is called the efficiency of utilization of the material, or more usually the "slab efficiency" of the chequerwork. The values for various chequerwork and times of reversal are shown in fig. 7.

There is still another factor to consider. Owing to the above-mentioned phase lag of temperature change—due to the fact that all conducting material offers a certain resistance to the flow of heat—the temperature of the surface during cooling lags behind the corresponding temperature during the heating period—*i.e.*, heat is always given out at a lower temperature than that at which it was stored—and this causes a further loss of efficiency. The value of this is shown on fig. 8 for different values of slab thickness and reversal time.

Having given the capacity of a particular furnace and the reversal time desired, we are now in a position to estimate the amount of chequerwork required in the regenerator. First calculate the total amount of heat contained as sensible heat in the waste gases during the period of one reversal—*i.e.*, half-cycle of operations. Let its amount be H. Then, if w is the weight per unit volume of the chequer material, s its specific heat, $(\theta_f - \theta_a)$, the difference between the temperature of the furnace and atmosphere, T the surface temperature efficiency, S the slab efficiency, and R the loss of efficiency due to resistance for any particular thickness t of slab chosen, we have

Heat absorbed and restored $= Q.w.s.\ (\theta_f - \theta_a)$ T.S. $(1 - R)$

where Q is the actual volume of chequer material, and is equal to $\frac{A\,t}{2}$ where both sides of the slab are exposed. The total area necessary to absorb the amount of heat H (*i.e.*, the total of gas and air regenerators) is then

$$A = \frac{2\,H}{t.w.s.\text{T.S. } (1 - R)\ (\theta_f - \theta_a)}.$$

Our argument so far has taken no notice of the difference of temperature which must exist between the solid surface and the gases in order to effect the transmission of heat between them. This difference depends upon the disposition of the solid surfaces, the distance apart, and the velocity of the gas flow. As in the case of recuperators, the best results are obtained by the use of thin solid slabs, narrow gasways, and high gas velocity, though it will be realized that the presence of dust in the gas streams, and the necessity for mechanically sound constructions, tend to place a limit to fulfilling our desires in these directions.

In the author's opinion, recuperators are preferable to regenerators for small furnaces, especially those where it is not necessary to have a large storage of heat for occasional use; and by careful attention to design they may be made very compact and highly efficient, and the heat losses due to the conduction through walls reduced to a very low figure. Regenerators will, however, continue to hold their own for very large installations where the added complication of reversing valves is not a serious drawback, for furnaces where a sudden large increase in heating rate is required occasionally, and also for large furnaces working at temperatures sufficiently high to cause rapid deterioration of the material of a recuperator.

We may sum up the conclusions at which we have arrived as follows:

1. It is better to arrange, if possible, for the heat conducted away through containing walls to be supplied by the spent gases rather than from the flame gases in the heating chamber.
2. Waste heat recovered and returned to the heating chamber can be utilized at a higher efficiency than in any external appliance.
3. Therefore it is only after full self-recovery has been practised that the recovery of waste heat for external purposes should be attempted.

Discussion.

The President said the paper was interesting to all, and particularly to those engaged on the industrial side of the gas industry.

Dr. Walter (Birmingham Gas Department Research Laboratories) proposed a vote of thanks to Mr. Booth. The subject discussed was, he observed, of especial interest to him. The design of furnaces did not receive the attention it deserved. While engineers had improved the efficiency of prime movers, inefficient furnaces were still installed. The figures obtained by the author were remarkably good. It appeared to him there were great possibilities in the use of nichrome as applied to recuperators. He would like to know what Mr. Booth's experience was of calorized steel recuperators.

Mr. J. H. Gee (Senior Vice-President) seconded the resolution.

Mr. Booth, replying to the vote of thanks, said he had used calorized iron with fairly good results; but with other calorized material his experiments had not been pursued. He had found calorized steel inferior to nichrome. Regarding the insulation of smaller furnaces, he pointed out that no standardized policy could be followed. If the furnace were to be used for short periods, it was no use insulating at all; but if it were to be used for a long time, then it was advisable to insulate. It was important to keep down the heat capacity of the furnace itself.

Leakage Surveys.

A paper on the reduction of gas losses was presented at the sixth annual convention of the Natural Gas and Petroleum Association of Canada, by Mr. Victor A. Ogilvie, Engineer to the Dominion Natural Gas Company of Buffalo, who describes a suitable installation for test connections employed on a leakage survey, where the main system is divided into small sections for testing separately. Three 1-in. taps are made in the main, and two rubber gas main bags are inserted at the centre tap, and inflated. A 1-in. riser is then screwed into the centre tap or bag hole, and water is poured into the riser until a hydraulic head is obtained which balances the gas pressure on each side of the inflated bags. If gas bubbles appear in the riser, it is an indication of leakage past one, or both, of the bags, and the trouble must be corrected. Insufficient inflation, sediment in the main, or other troubles, may necessitate re-setting the bags to secure a positive seal. One of these bag installations is required at each point where stoppage is needed to secure a completely isolated section. It is very necessary that each bag installation is an absolute seal, as the accuracy of results depends a great deal upon the degree of skill exercised in securing a complete isolation of the tested section. To proceed with the test, a portable test meter is connected with flexible hoses attached to the 1-in. taps on either side of the gas bag space. The meter is equipped with valves and unions necessary for control and convenience in erecting and dismantling the set-up. There is a gauge to indicate the pressure of the gas measured. If there is too much pressure fluctuation to assure reliable measurement, it is advisable to insert a regulator in the riser stem on the outlet side of the installation. A by-pass is provided, to speed-up the flow of gas in filling the isolated section in the case of a large-capacity test.

THE MODERN DRAWING OFFICE: ITS PLACE IN THE SCHEME OF GAS-WORKS MANAGEMENT.

By J. E. Ledingham, of the Tottenham District Light, Heat, and Power Company.

[Before the London and Southern District Junior Gas Association, March 20.]

In undertaking to read a short paper on the drawing office, I am afraid that it will hardly be possible to bring forward entirely new information in the space available. This remark is addressed particularly to those members present who already control drawing offices of their own—but I hope that such members will find interest in what may be a different viewpoint, and lead a useful discussion. The paper is written chiefly for those who have no great knowledge of the modern drawing office, or of its correct place in the scheme of gas-works management. A brief retrospection will be useful.

The drawing office of days gone by was undoubtedly regarded by the executive officers of most engineering concerns gas-works included—as a more or less necessary evil; "necessary" because very little constructional work could be carried out without a drawing of sorts, and evil because the drawings of that day were, perforce, only artistic pictorial representations of the completed piece, leaving very much of the detail work to the effort and judgment of the shop foreman and workmen. All honour to the pioneers on both sides; but the system was wrong. Too often was the article, as finally produced, the outcome of a system of "trial and error" during production, wherein much time and energy were misplaced and material wasted. There was little co-operation between the shop and the drawing office; and, as one may well imagine, the relationship between the heads of these sections was none too cordial. They blamed each other for failures, while each laid claim to success. Such conditions existed many years ago; but the evils have been gradually eliminated until the drawing office now stands in a proud position. It is the engineer's "technical problem solving department," and may be likened to the "hub" of the wheel of constructional activity, the axle of which is the chief engineer.

To those members not directly connected with the constructional engineering side of our business, it will not be amiss to point out that the modern gas-works—considered as a whole—is a very self-contained institution. It constructs and maintains its own general plant, buildings, roads, railways, and wharves, possesses the various workshops, machinery, and tradesmen for carrying out such work, generates its own steam, hydraulic, and electric power for driving its running plant, handles mechanically its raw materials and bye-products, and delivers the latter to customers by its own fleet of motor lorries, and so on, with all sorts of ramifications. I mention these things simply to illustrate the classes of work which the chief engineer expects his drawing office to deal with down to the minutest detail, and for which he requires designs, detail drawings, specifications, and schedules of materials, for issue to his workshops, or, if his own shops be too busy, to issue for tenders.

The drawing office, properly organized and working with method and system, thus becomes a very useful section; and I now propose to show how the duties of a small nucleus staff can be best arranged to deal efficiently and economically with such work. My explanation will be clearer if you will refer to the diagram in which the personnel of the drawing office is shown in the form of a genealogical tree.

The organization of the brain values of his staff rests with the chief draughtsman; and in order that the ever-present variety of work may be efficiently dealt with, it will be clear that the nucleus staff must be carefully selected, capable, hard working, and contented men—earnest and thorough. It will be seen that the chief draughtsman deals personally with all the technical correspondence calling for details of work in hand or placed to contract, draws up all specifications, issues inquiries, and analyzes tenders, regulates contracts, correlates technical information, arranges and supervises technical experiments, directs inspection of materials, and receives the reports of the clerk of works. In addition, of course, he directs the design and passage of all work through the drawing office, and is responsible for the maintenance of discipline. In the last-named items he is directly assisted by his two leading draughtsmen; one (called first assistant) preparing the original designs for the more important schemes on what may be called the "mechanical" side, the other (called second assistant) on work of equal importance on the "building" side. These men, in turn, feed the senior draughtsmen with work, the general scheme for which has been approved by the chief engineer. The duty of the senior draughtsmen is to prepare fully-dimensioned and accurate scale general arrangement and detail drawings in pencil, and a complete schedule of materials and weights for purposes of ordering. In this they are in turn assisted by junior draughtsmen, works pupils, and apprentices, who thereby gain a very necessary experience and training. An endeavour is made to sectionize the work—that is to say, to keep the same class of work to one man, or group of men; but it is obvious that a generous overlapping of sections must and does occur. The advantages of this overlapping will be equally obvious in that it relieves the work of the monotony of sameness so far as the draughtsman is concerned, and protects the office against the unavoidable absence of individual members of the staff through sickness and holidays.

Subsequent to the completion of the pencil drawings, these are carefully checked by a senior or leading draughtsman, and are passed to the tracers (male or female), who trace the work in indian ink upon standardized sheets of tracing linen. These tracings are again checked, and afterwards passed to the printer for the requisite number of prints. There are very few drawing offices to-day which do not include in their equipment an electric photo printing copier—a cheap and speedy method by which to obtain many types of prints—*e.g.*, the "wet process" prints, "Ferro-Prussiate," "Ferro-Gallic," and "Pellett," and the dry process of "true-to-scale" prints, "Ordoverax," "Sepia," and "Ozalid." The "Ferro-Prussiate" or blue print is by far the commonest production and cheaper than any other; but it is in many ways an unsatisfactory article, shrinking unequally during the drying process, difficult to read in dark places, and likely to fade in a strong light. Its shrinkages render it unsuitable for small-scale architect's drawings whereon dimensions are conspicuous by their absence, and where the user is compelled to apply a rule or scale. White prints of the "true-to-scale" variety are used for all such work. Time will not permit a detailed description of these processes; but it may be well to state that the "Ozalid" is the most recent introduction. It produces a print having a deep chocolate line on a white ground, is true to scale, no more costly than the blue print, and is obtained more rapidly. It is handy; but its permanency only time can prove.

The recorder is employed to classify, comprehensively and accurately to index and record all office drawings and tracings, to put these away, keep them in good order, and find them rapidly when they are required. The "logging-in" of all drawings received or issued is of great importance. It requires the provision of (1) a well-bound drawing register in book form, numbered in folio and bearing printed headings to vertical columns—the headings stretching completely across the folio opening. The "headings" in sequence reading from left to right are as follows: "Series No.," "Drawing No.," "Description or Title," "Office of Origin," "Original No.," "Date Made or Received," "Correspondence No.," "Section Concerned," "Order or Contract No.," "Copies Issued and Date," "Remarks and Cross References." (2) A Stolzenberg type card-filing cabinet for the reception of coloured cards 6 in. by 5 in.—as many drawers to the cabinet as there are colours (or sections) to be considered. The cards will lie behind the usual buff-coloured alphabetical index division cards in each drawer. Each card will bear the following printed headings to vertical columns: "Description," "Maker," "Drawer," "Drawing No."

The system is extremely simple but very effective, and particularly so when a piece of work involves not only the original schemes evolved under instructions received from the chief engineer, but also a works portion and a contract portion, each forming part of the finished piece. The drawings for the entire piece of work would all bear the same series number, and would each bear a sub-number in the true chronological order of their advent. They would be found at a moment's notice, now or years hence, by reference to the cards; and if required, the history attaching to each one can at any time be obtained from the register. They will be found all together in the storage drawer, arranged with the parent drawing at the bottom, and the drawing last made or received on the top. There is no waste of space in storage drawers, since "series" is laid upon "series" until the drawer is full, and the next lower drawer of the press (emptied of its "years old" accumulation to a more remote storage) is available to receive current work. All tracings (negatives) are stored in an exactly similar manner, but in the "tracings" drawers. Only in very exceptional circumstances should the office copy be loaned to the works; and when this does occur, the early return must be urged and enforced. It may appear to one unused to a system of this kind that its adoption would lead to a large amount of clerical work. This is not so. The information required under the printed headings is simple and terse.

In a gas-works where the maintenance of running plant is of such vital importance, it is imperative that the full set of contractors' working drawings to which a plant has been constructed, should always be available. By adopting this precaution, not only can breakdowns be speedily dealt with, but the cause of a breakdown can often be traced to an inherent defect in design, undetected in the original scrutiny, the defect remedied, and the likelihood of further breakdowns in the same part be reduced to minimum. The scrutiny of contractors' drawings prior to the manufacture of new plant should receive special attention on the part of the gas-works drawing office, and the specification should be so drafted as to allow the chief

engineer to call for any reasonable modifications to the contractors' design which he may consider beneficial. All "approved" contractors' drawings should be submitted in duplicate. Both copies should receive the registered number. One of the copies should be retained by the drawing office as "office copy," the other one should be issued to the works, to facilitate inspection during erection.

The recorder acts also as librarian—indexing under a card system those articles appearing in the Technical Press and marked for record by the chief engineer or his heads of departments. Further, he lists and puts away all catalogues received from various manufacturers. In small offices, the duty of the "recorder" may be combined with that of the printer; but in large offices it will require the whole time of one person —(say) a partially disabled employee—who will give it special and precise attention. The clerk of works acts as a link between the drawing office and the works. It is his duty to see that all work is carried out in strict accordance with the drawings and specifications issued by the drawing office. He is indispensable on all work let to contract, keeping a rigid check, and signing all vouchers daily for work carried out on a priced schedule basis. The inspector is employed to visit the works of contractors, examining and testing, gauging and stamping all such pieces of material and plant which cannot be so conveniently treated after delivery. All his reports and test sheets are filed with the contract papers. When the nature of the work permits, it is sometimes convenient to depute the clerk of works to act also as inspector, but only on visits of short duration.

In so short a paper it is not possible to devote any more time to a more detailed description of the routine duties of individuals forming the drawing office personnel, and it now remains to describe briefly the method and system by which drawings are produced, "issued to," and "dealt with" by the works section concerned.

In most cases the chief engineer institutes the "requirement," and in collaboration with his chief draughtsman decides upon the scheme in its broad outline and idea. Designs are then prepared by the drawing office probably in two or three forms; and after careful criticism and discussion, from all points of view, the necessary general arrangement and detail drawings are prepared in pencil only—for discussion with the works engineer. It is impossible to emphasize too strongly the necessity for close and friendly co-operation between the works and the drawing office; and to this end the works engineer and chief draughtsman together examine and discuss all important drawings immediately prior to their completion, in order to modify or embody features which, in the works engineer's opinion, will lead to simplification either in manufacture or in subsequent maintenance. It is also possible that his specialized knowledge of local conditions will allow of his pointing out a difficulty unforeseen by the designers. Such advice is very valuable to both designer and draughtsman, inasmuch as the very nature of their task trains them to think along prescribed lines; and though they will include all the main essentials to a job, they are apt to omit some useful trimmings, or ignore awkwardness in erection.

After consultation with the works engineer, the drawings are amended, if necessary, and submitted to the chief engineer (together with an estimate of the costs of carrying out the work) for final modifications and approval, and instructions as to the division (if any) of the work between "works" and "contractor." The chief draughtsman then issues the necessary number of shop copies to the works engineer, accompanied by a memo explaining clearly but concisely the full extent of the work to be carried out by each of the works sections concerned. The memo states also the extent of any supplies placed or being placed to contract by the drawing office, and the date that these are due for delivery. A schedule of materials required, complete down to the last bolt and washer, is placed on all shop copies issued; and it is convenient to wash-in in a standardized colour—(say) crimson lake—all pieces forming any part of the supply by contract. To facilitate the smooth passage of work through the shops, it is a recognized rule that non-standard parts shall be excluded from designs, except in very special circumstances. The enforcement of this rule has the effect of decreasing the varieties and shapes and sizes of stock held in the works store, and tends to uniformity of practice in the drawing office in the selection of those materials and sizes included in the drawing office standards list.

The foregoing procedure enables the works engineer to allocate to the job the appropriate works cost number, and to make out the necessary demand notes on the works stores for the withdrawal of the requisite materials. A duplicate set of shop copies is issued simultaneously to the clerk of works, who will report progress.

No alteration or variation is to be made to the details as shown on a completed drawing without first obtaining the consent of the chief draughtsman, whose duty it is to preserve accurate records. If the alteration is authorized, it is duly recorded on all copies extant; the office copy receiving in addition to the illustration the reason for, and date of, the amendment. In connection with this clause the writer favours the idea that the draughtsman responsible for the actual drawing-out of any important piece of work should be deputed to visit from time to time the scene of erection until the work is completed. The work of the drawing office in respect of any one job terminates at this point so far as the executive side is concerned; but after the installation has been completed, the small-scale representation is made on the general works plan, for purposes of final record.

In writing this short paper I have had in view the main principles to be observed rather than a detailed description of any one system; but I am indebted to my own Chief Engineer for his kind permission to include certain features of organization instituted by himself and which work well in practice.

Discussion.

The PRESIDENT pointed out that the main object of a gas company was to make dividends; and when any new work was projected, this was the underlying motive. Every scheme put forward must be accompanied not only by an estimate of the actual work, but also by an estimate of its working effects. Mr. Ledingham, he thought, had not stressed this point. The organization outlined by the author was Utopian. Mr. Ledingham had suggested that no alteration or variation should be made to the details as shown on a completed drawing without first obtaining the consent of the chief draughtsman. He did not quite see how the author was going to enforce this idea.

Mr. LEDINGHAM said that, regarding the financial aspect mentioned by Mr. Booth, no work was put forward until it had obtained the full sanction of the engineer, who, of course, was always supplied with an analysis of costs of the work in operation. The organization outlined in his paper referred to a large drawing office; but it was easy to conceive a smaller system based on the same idea. At all times co-operation between drawing office and works staff was not only desirable, but necessary. This co-operation was practised to advantage at Tottenham. The works engineer should be consulted before any drawing approached the stage of completion. This eliminated a great deal of after-alterations.

Mr. A. Broadbent, of the Gas Light and Coke Company, said that the lay-out outlined in the paper was admirable. Did Mr. Ledingham find it necessary to have drawings under lock and key?

Mr. Ledingham replied that confidential drawings were always locked up, but that general drawings were not. As he had stated in his paper, a recorder was employed to handle drawings. He kept a log of all drawings, and it was always possible to trace any one of them.

Mr. Cleave Cross remarked that the paper had been written from the point of view of a draughtsman, to whom, of course, the system was undoubtedly ideal. If they asked a chemist to set-out how he would like to run a works, he too, from his viewpoint, would explain an ideal system. With a scheme such as put forward by Mr. Ledingham, he suggested that the powers of the drawing office would be out of proportion.

Mr. Ledingham emphasized that unless there was give and take on both sides any system was bound to fail. All work, he pointed out, was directed by the chief engineer, and works engineers and chemists were consulted when any new scheme was proposed.

Mr. Grogono said that, from financial considerations, it was necessary that work should first go through the hands of the works engineer, who would pass it on to the draughtsman.

Mr. Frost remarked that Mr. Ledingham, at the outset of his paper, had stated that many drawings were purely artistic. He could endorse this statement. The draughtsman, of course, atoned for this by pleading for closer co-operation; and he was sure that all heartily agreed that this co-operation was necessary. The initial details of any scheme should be practical. In the South Metropolitan Company, when any important work was projected, the drawing office found out what had already been done, and they got advice from works superintendents and foremen. After the work was finished, any subsequent alterations were carefully recorded, and old drawings destroyed.

Mr. A. J. Nichols, of the Gas Light and Coke Company, remarked that little had been said about the works draughtsman, who had to be "everything combined."

Mr. Ledingham thought it preferable to have all the draughtsmen under one roof.

Mr. Bevington asked how the mains and services were recorded.

Mr. Ledingham replied that, as new mains were laid, they were drawn on large-scale Ordnance survey maps. Small sections of these maps were issued to the main-laying gangs, and all necessary information was recorded. No records of services were kept in the drawing office.

Mr. Newton Booth, in bringing the discussion to a close, said that Mr. Ledingham had given them a new subject to record in the Transactions of the Association. The idea outlined was certainly a step in the right direction.

Mr. V. P. Hart, of the South Metropolitan Gas Company, proposed, and Mr. W. R. Moger, of the Tottenham District Light, Heat, and Power Company, seconded, a vote of thanks to Mr. Ledingham.

WALES AND MONMOUTHSHIRE JUNIOR GAS ASSOCIATION.

A meeting of the Association was held at Swansea on March 21. Mr. B. J. Bell, President, was in the chair, and was supported by Mr. W. H. Johns (Engineer and Manager of the Swansea Gas Light Company), Mr. E. Ablett (Secretary), Prof. F. Bacon, M.A. (Professor of Engineering, University College, Swansea), and Mr. A. J. Bond (Aberavon). The Chairman said they were very grateful to Mr. Johns for the facilities provided, and for giving them the opportunity to visit the Morriston Works.

Mr. Johns then delivered the following

ADDRESS.

I understand that the programme of the Educational Scheme of the Institution of Gas Engineers is shortly to be published. Mr. Walter Hole has given details of the scheme to various associations; and if you have not read any reports, you will doubtless be interested in a brief outline of the scheme. The course is of interest principally to those who have just entered, or who are about to enter, the industry. Students are divided into two groups—those who have ample facilities to attend an educational institute which has the approved scheme in operation, and those who have no such facilities. In the first place I will deal with the former group. The course comprises a period of five years, divided into two phases, one of three years and one of two years. During the former phase the student qualifies for the "Ordinary" Certificate; the subjects of study for the first two years being ancillary ones—mathematics, chemistry, &c.—the third year being devoted to gas engineering and/or gas supply. When the "Ordinary" Certificate has been granted, the student qualifies during the second phase for the "Higher" Certificate. The first year of this phase is devoted to further study of ancillary subjects, and the second year to gas engineering and/or gas supply. Upon attaining the age of 23, those students in possession of the "Higher" Certificate may sit for the "Diploma." They are required to have had practical experience, must possess a general educational certificate, such as the Matriculation or an approved equivalent, and must have obtained "Higher" certificates in respect of both gas engineering and gas supply. The Sub-Committee of the Wales and Monmouthshire District Institution appointed to deal with the scheme are considering the question of two centres, one at Cardiff for eastern students, and one at Swansea for western students. In the case of students who are so unfortunately placed that they are unable to attend an educational institute having the approved course, they may study the ancillary subjects at an institution in their neighbourhood, and later, having attained the required proficiency, ask to be examined in gas engineering and/or gas supply. The City and Guilds Examinations will, of course, be open to those who are unable to undertake the course. My object in remarking upon this education scheme is to emphasize the urgency of fitting yourselves to qualify for lucrative posts; as competition is likely to be keener in the future than hitherto.

The Morriston Works.

I understand the principal object of your visit is to inspect the new works at Morriston. They were fully described in my address to the Senior Association, reported in the "Journal" for Nov. 10, 1924; and accordingly I only propose to state a few features of the works, in order to make your inspection more interesting. Ferro-concrete was extensively used. The site, consisting of virgin marsh land, made up to the extent of 7 ft., was a difficult one for the construction of foundations, which consist generally of ferro-concrete slabs supported by piles and beams. The following are also constructed in ferro-concrete: Coal grabbing pit, coal breaker pit, coke crane gantry, coke storage hoppers, tar and liquor well, elevated water tank. The works are laid out for an ultimate capacity of 12 million c.ft. of coal gas and 6 million c.ft. of water gas per diem. In designing No. 1 section of coal gas, the requirements of No. 2 section in regard to subsidiary plant were duly considered; and wherever expedient, plant and buildings have been constructed sufficiently large for such future requirements. The retort house, consisting of 14 beds each of ten retorts of large capacity, is operated on the principal of two shifts per 24 hours; each shift comprising eight hours with intervals of four hours. The retorts are charged and discharged by a Drakes' stoking machine; the discharged coke being delivered into the tube of a "G.N." hot coke transporter which forms a channel to the outside quenching bench. This transporter is also employed for feeding the furnaces; and in this case the tube, after receiving the discharge of coke from a retort, is inclined, to form a channel to the furnace mouth.

The coke is removed from the quenching bench by a crane fitted with a skip of a capacity of two tons. The skip is guided into the trough of the quenching bench, and, imposing its weight upon operating arms, automatically opens the doors of the bench. In this manner the coke feeds from the bench into the skip, which is hoisted by the crane. When the operating arms are relieved of the weight of the skip, the doors of the bench automatically close by the action of counter-balance weights working over pulleys. The coke storage hoppers, yard heap, water gas plant—this is yet to be erected—and the coke separator are set out within the radius of the coke crane; and accordingly transport of all coke, breeze, and ashes may be undertaken by the crane without recourse to separate means of sectional transport.

The engine and power house is constructed for the requirements of two carbonizing units, and embodies: Electrical generators for day and night load; coal gas exhausters; water gas exhausters (not yet installed); tar and liquor pumps; and gas compressors necessary to feed the holders at the works at Oystermouth Road through a 12-in. high-pressure connecting main. The following machinery is operated by electrical power generated on the works: Coal elevators, stoking machine, "G.N." hot coke transporter, coke quenching pumps, coke screening apparatus, coke recovery plant, sulphate of ammonia elevator and centrifugal drier. The steam necessary for driving the electrical sets is obtained from breeze-fired water-tube boilers.

Ammonia and naphthalene extraction are effected in separate rotary brush scrubbers, erected in one group and operated by common duplicate engines; the connections being arranged so that naphthalene extraction is conducted after purification. The purifiers consist of five boxes each 40 ft. square by 6 ft. deep, one of which acts as the catch box. The provision of the patent reverser valves enables the purifiers to be operated on the upward and downward or forward and backward rotation principle, as desired.

The sulphate of ammonia plant consists of a complete equipment for the production of 4 tons of dry neutral sulphate per diem. Neutralizing, by the Hooper and Weyman patent process, is effected by a special feeding device which introduces the correct proportion of alkali in the form of carbonate of ammonia into the basket of a centrifugal drier. Upon discharge from the drier, the sulphate is carried by an elevator to a high point in the building, where it is mechanically screened, and any lumps in the mass reduced to uniformly

granular condition. The sulphate of ammonia crystals fall from this elevation to the stores, and are further dried by exposure to the atmosphere in falling. I particularly recommend those of you who are interested in the manufacture of sulphate of ammonia to examine this plant, as there are very few of its description in operation. After you have inspected the works I shall be only too pleased to answer any inquiries you may wish to make.

A tour of the Morriston Gas-Works was then made under the guidance of Mr. Johns, Mr. Ablett, Mr. Cunniffe, and others on the staff of the Swansea Gas Light Company; the members subsequently adjourning for tea at the invitation of the Chairman and Directors of the Company.

Prof. Bacon then delivered the following

ADDRESS.

The lecturer said that the oldest learned society in this country was the Royal Society, which received its charter from Charles II. in 1662. It was before this Society that William Murdoch's paper on the economic employment of gas light from coal was read in 1808, for which he was awarded the Rumford Gold Medal. Of late years, technical societies and technical newspapers had multiplied to a degree which was positively embarrassing. Specialization appeared to be reaching the breaking-point. On the other hand, the inter-dependence of the industries grew greater every year. It was not very long ago that the use of gas was practically confined to domestic and street lighting. According to Sir Arthur Duckham there were now over 3000 known industries in which gas was used, on an average, in seven different processes. Mechanical engineering too had invaded an immense number of industries, and he was sure that they would agree it now played an important part in gas-works practice, as exemplified in the fine new works Mr. Johns had put up at Morriston.

The industrial prosperity of Great Britain had been built up on cheap labour and cheap coal. Neither labour nor fuel were cheap any longer; and the only hope for the future seemed to be in making the most of these now expensive basic commodities by judiciously co-ordinating the fuel producing, transforming, and consuming industries. This was a task which would entail all the scientific knowledge, all the engineering skill, and all the mutual co-operation and goodwill they could command.

The Engineering Department of the University College of Swansea would shortly possess spacious and well-equipped laboratories, the possibilities of which he hoped the local industries, including the gas industry, would exploit to the full. It was the intention to pay special regard to combustion problems. Thanks to the generosity of a firm of water-tube boiler makers, a complete boiler plant was now being installed which would be the most up-to-date experimental plant possessed by any educational institution in the country. It would comprise all the scientific instruments and auxiliaries to enable it to be used as a mighty calorimeter in which fuels could be tested on a commercial scale and under conditions reproducible in industrial plants. He invited the Swansea Gas Light Company to co-operate in enabling him to demonstrate to the industries of the district what could be done in the way of burning gas coke on a chain-grate stoker with mechanical draught, or with natural draught by aid of the "Sandwich" system which Mr. E. W. L. Nicol, of the London Coke Committee, had done so much to develop at Greenwich, Barton, and elsewhere. The combustibility of coke was a live problem for the gas industry as well as for the steam power engineer.

Prof. Bacon concluded by extending an invitation to members to attend the meetings of the Institution of Mechanical Engineers, and also to the Association to pay a visit to their new Laboratories at Singleton.

Mr. Johns expressed his gratitude to Prof. Bacon for his address. Referring to the smoke problem, he remarked that the waste taking place, particularly in their own industrial area, was very great, and vast opportunities existed for study in this work.

Mr. D. M. John (Aberdare) proposed a vote of thanks to Prof. Bacon. This was seconded by Mr. T. A. Canning (Newport).

Mr. B. J. Bell moved a vote of thanks to the Chairman and Directors of the Swansea Gas Light Company and to Mr. Johns, Mr. Ablett, and the members of the staff of the Company who had acted as their guides on the visit to the works. They were grateful to all connected with the Swansea Gas Light Company for the help given, which they highly appreciated.

Mr. T. A. Canning seconded the vote.

Hull Chemical and Engineering Society.—At a recent meeting of the Society, Mr. N. Simpkin, M.Sc., A.I.C., Director of Research to the Lancashire and Cheshire Coal Research Association, gave a lecture on "Some Aspects of Low-Temperature Carbonization."

PUBLIC LIGHTING BY GAS.

The Work of Messrs. William Sugg & Co., Ltd.

Much about public lighting by gas, together with a good deal of other information that is likely to prove of value to them, was gleaned on Thursday afternoon last by a party of some seventy municipal, county, and lighting engineers, who visited the extensive Westminster Works of Messrs. William Sugg & Co., Ltd. Assembling at the Ranelagh Works, in Chapter Street, they were welcomed by Mr. Philip Sugg, the Chairman of the Company, who devoted himself for the remainder of the afternoon to the guests—as did also the other Directors, Messrs. J. W. Lofts, W. Mattock, and Anthony Sugg.

The inspection was excellently well timed, in mid-week, when everything was in full swing, and the 750 to 800 employees were all busily occupied. That the visitors were astonished at the hive of industry into which they had walked was evident; but that they should have been surprised was only natural. As Mr. Philip Sugg himself said, the works are in a way unique, in that they have been on full time, and sometimes on overtime, for the last four years; and one is inclined to agree with him that such a gratifying state of affairs, on 80 p.ct. gas lighting, indicates that there must be some remarkable awakening in the general attitude towards public lighting. Most municipal engineers and local authorities are, he thinks, now convinced that it is impossible to serve present-day conditions with a standard of lighting applicable to former times. It is no doubt because there has been manifested—largely through the efforts of the lighting engineers—this increased interest on behalf of the public, that the firm have been fortunate enough to keep going full speed ahead over so long a period.

In many of the departments of the factory one would have liked to linger longer; but the tour was a long one, and the time-table had to be adhered to. There was an inspection of the foundry, where brass, gun-metal, iron, and aluminium are cast into various forms for all kinds of lighting components; and the machine shops, where these castings are turned and partially fitted. Then in the automatic shops all kinds of small components are turned wholly or partially by automatic machinery, in the brass finishers' shops other small components are made, and in the stamping shops sheet-metal lamp components are stamped or pressed to shape and sometimes joined together by acetylene welding. As much time as could be spared was devoted to the spinners' shops, in which spinnings of all kinds for lamp casings, reflectors, &c., are made in iron, copper, brass, and aluminium. In addition to the metal polishing shop, the assembly shops, and the tinsmiths' shops, there are testing rooms in which every lamp and burner is adjusted and thoroughly tested before leaving the factory. A department of more than usual interest is to be found in the steatite shops, which are employed in the turning of steatite for use in gas burners and also as insulators for electrical work. There are separate stove shops, in which the manufacture of gas cookers is carried on.

Early History of the Firm.

After tea, Mr. Philip Sugg told the visitors how greatly he and his co-Directors had appreciated the opportunity of showing them round the factory, and explaining to them something of the many processes which went to the making of a gas lamp. The factory had been in course of extension for a great number of years, which accounted for the fact that it was perhaps not quite what one would imagine that a modern factory would be. In a way the firm gloried in this, because it was an indication of the age of the business. It was originally started as a private business, somewhere about 1837, in Marsham Street. That was in the time of his grandfather. It was the son of that Mr. Sugg (and his, the speaker's, father) of whom many of those present had happy memories. A move was made into Vincent Street about 1861, and, as was the custom in those days, Mr. William Sugg lived on the works. In some respects the works which they had seen that day were unique—for one thing, because there were so many processes carried on under one roof. It was seldom that one came across a works so thoroughly self-contained. There was everything there that was required for the production of gas lamps for public and domestic lighting.

Progress in Public Lighting.

Mr. J. W. Lofts then lectured, with the aid of a much-admired series of photographic lantern slides, on "Public Lighting by Gas." Pictures were shown of the early gas lamps introduced by Mr. William Sugg, and then of his later designs; the step-by-step development of present-day designs being thus portrayed. He showed clearly the economy to be secured by conversion to the inverted system of lighting, and expressed his surprise that, in spite of this, it is still possible to see in London upright mantles in hundreds, if not in thousands, of cases. "If you want to save the ratepayers' money," he said, "exchange upright burners for inverted fittings." For economy's sake, many thousands of conversion fittings have been, and are being, put into use in all parts of the civilized world—all over these Islands, and also in France, Belgium, Denmark, Norway, Sweden, Egypt, India, China,

Singapore, Australia, South America, and so on. One of the latest countries to take-up conversion fittings is Turkey, where they are giving great satisfaction. Several orders have come from Egypt, where they are so satisfied with them that the process of conversion is becoming general. Two small mantles are, it is found, cheaper to maintain than one universal size. There were many illustrations shown of the well-known "Littleton" lamp, which lends itself to various clusters of burners and styles of fitting.

Mr. C. Chambers Smith proposed a hearty vote of thanks to Mr. Lofts for his lecture, and to Mr. Philip Sugg for his cordial welcome and the visit to what was a remarkable factory. They would all go away with a very good opinion of the firm and of the perfection with which they carried out their work.

Mr. Helford seconded the vote; and Mr. E. F. Spurrell also returned thanks for an enjoyable afternoon. The latter speaker said it was sometimes difficult to induce corporations to pay the price that was necessary to secure a good article; but they must endeavour to get them to buy the best.

Captain W. J. Liberty voiced his personal appreciation of the kindness of the firm in making the visit so pleasant and profitable.

Mr. S. B. Chandler, speaking as a visitor, said the subject which Mr. Lofts had taken for his lecture was one of paramount importance to each one of those present. Street illumination was one of the prime services which undertakings supplying forms of energy for lighting had to deal with; and it was highly important that ratepayers should have the best that was available. The relations of his own undertaking with the engineers and surveyors of the various Councils in the area of supply were of the happiest; and he was very glad to think that the officials in question were at all times willing to listen to proposals in connection with an improvement of the public lighting. This was a highly satisfactory state of affairs; and he submitted that, if they desired to see progress in this direction, they must have co-operation.

Captain H. F. Wilkinson (the Surveyor to the Tottenham Urban District Council) said he appreciated very much the opportunity given to engineers generally of going there and seeing over the works. Those of them who were unacquainted with anything in the shape of manufacturing on the lighting line had had a most interesting time. So far as relations with the gas companies were concerned, he also considered that co-operation was the way to assure success and efficiency.

SOME APPLICATIONS OF THE TOWN GAS FIRED BOILER.

By J. N. Williams.

References to the general subject of utilizing town gas for steam generation have been made from time to time in the "Journal." These references have surveyed the question from the aspects of cost, load factor, capital cost, and reliability. It cannot be claimed to-day that gas, in all circumstances, is superseding solid fuel; but the time is not far distant when this will be the case, for there are most pronounced tendencies in this direction. Having regard to the present cost of various forms of fuel, all one can say is that far more steam should be generated by using town gas, and that for moderate steam requirements under 1000 lbs. per hour, with any degree of intermittency in demand, where labour charges are material, there is a highly satisfactory case for town gas. Every instance must be investigated on its merits; and in this connection there are inflexible rules. Data must be investigated as closely as possible; the "rules-of-thumb" usually associated with steam generation must be forgotten; and, if a steam test is indicated to arrive at actual conditions, then a test must be conducted.

It will probably be of help to those seeking to push gas sales for steam generation if we briefly describe three installations of town gas fired boilers.

Town Gas Fired Boiler for Testing Fittings.

An interesting installation is that at the works of Messrs. J. Hopkinson & Co., Ltd., the well-known manufacturers of boiler fittings. The town gas fired boiler installed at these works is used for testing steam fittings, and has a normal working pressure of 750 lbs. per sq. in. The boiler is horizontal and is fired with a gas jet per tube without primary air, induced draught, or booster. A few particulars of this boiler will be of interest. It is capable of evaporating 343 lbs. of steam per hour from and at 212° Fahr. with 25 ft. of chimney. The diameter of the boiler is 29 in., and the length between tube-plates 4 ft. The shell plate is 1 in. thick, the tube-plates being $\frac{7}{8}$ in. The boiler has 26 tubes, 12 of which are stay tubes. For this high pressure of 750 lbs. per sq. in. there are three $1\frac{5}{8}$ in. diameter stays screwed into the two tube-plates.

On the installation of the boiler, a test was conducted, with the following result:

Working pressure	750 lbs. per sq. in.
Chimney draught	$\frac{1}{10}$ in. water gauge.
Temperature of products	352° Fahr.
Temperature of feed water	47° Fahr.
Town gas	450 B.Th.U. per c.ft. (net).
Water evaporated (actual per hour)	316 lbs.
Water evaporated (from and at 212° Fahr. per hour)	410 lbs.
Gas consumption per hour	1100 c.ft.
Gas per lb. of steam evaporated from and at 212° Fahr.	2·68 c.ft.
Boiler efficiency, unlagged	80 p.ct.

The main advantage of installing a town gas fired boiler for steam testing lies in the fact that, as a rule, the steam demand is intermittent. A batch of valves or fittings is put through together; the testing of these occupying (say) half a day a week.

At a large engineering works in London where the speciality is the overhaul and repair of feed pumps, all the testing is done by means of a town gas fired boiler. Prior to the installation of this unit, a stock of coal had to be accommodated in an already congested site, and the change-over to gas resulted in valuable space becoming available for another important operation. The costing system connected with this pump repair work was carefully organized; and one of the greatest advantages of the gas-fired boiler was found to be that the gas-meter reading gave the actual charge for the steam used in testing the repaired pump. As the steam consumption varied considerably with differing sizes of pumps, this was an important matter.

Town Gas Fired Boilers for Rubber Industry.

Among the many town gas fired boilers installed in connection with rubber process work is a notable installation at the works of the Reliance Rubber Company, Upper Thames Street, E.C. 4. Mr. Fordyce Jones has installed the most up-to-date appliances, and is adopting the most modern methods throughout. The gas-fired steam boiler has an evaporative capacity of 806 lbs. of steam per hour from and at 212° Fahr. The working pressure is from 80 to 100 lbs. per sq. in. Reducing valves bring the pressure down to 15 to 60 lbs. per sq. in. according to the demand for the particular process. The gas-fired boiler is at present supplying steam to a pair of masticating rolls, two vulcanizers, and six presses; and it is estimated the boiler has ample capacity for two additional presses. The main consideration underlying the installation of this boiler was that, owing to the nature of the processes, dust and dirt had to be entirely eliminated. The boiler has been rendered entirely automatic in action, and stand-by charges reduced to the minimum. The automatic regulation of the feed water supply is undertaken by a thermofeed which governs the steam supply to a horizontal duplex boiler feed pump. The gas supply is controlled by an automatic regulator which functions on the boiler pressure.

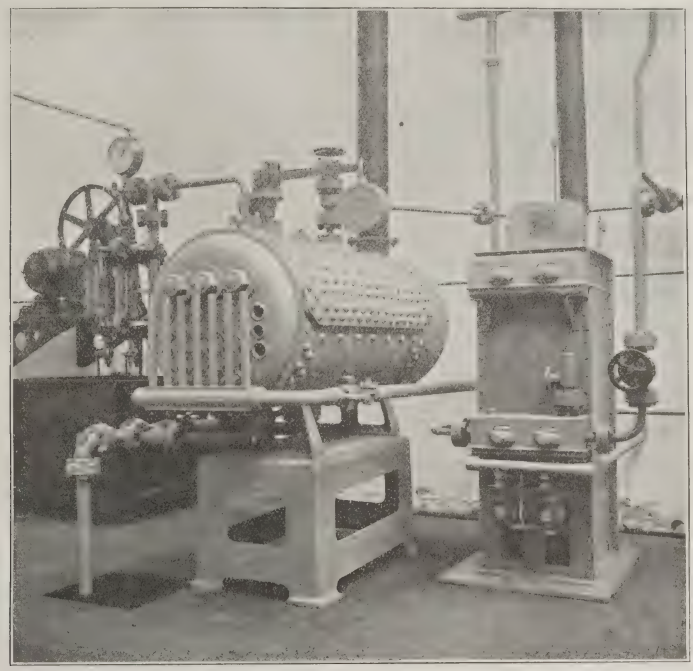
This installation is interesting to those engaged in gas sales, as we here have a case where the success of the works operations depends almost entirely on the elimination of the dirt which is a characteristic of solid fuel firing.

The Heating of the "Capitol" Cinema.

The "Capitol" Cinema, Haymarket, which was opened a few weeks ago, has been hailed by the Press as Europe's "finest and most luxurious cinematograph theatre." It is of interest to note that the "Plenum" heating is entirely dependent on gas-fired units—in this case water heaters. There are numerous unique aspects of this installation. Two boilers are installed on the roof, and as considerable lengths of chimney would have detracted from the architectural features, small induced draught fans were incorporated and sufficient flue pipe supplied to clear the roof of the low boiler house. The fans are each capable of maintaining $\frac{1}{4}$ in. W.G. Both gas-fired boilers are horizontal; the larger is 3 ft. diameter by 5 ft. 9 in. long, the smaller 2 ft. 3 in. diameter by 5 ft. 6 in. long. Under the draught of $\frac{1}{4}$ in. W.G. the larger boiler will deliver 1,280,000 B.Th.U. per hour, the smaller 700,000 B.Th.U.

The hot water circulation through the system is effected by a centrifugal pump. Though the boilers are installed on the roof of the "Capitol," the "Plenum" chamber is just above ground level. The cold air enters through a grille in the "Plenum" chamber wall. It first passes over a battery of hot water pipes, is washed, and then passed through the main heating battery. The air volume is computed from a specific allowance per person per hour. Assuming the theatre to be fully occupied, the system which is in commission warms the theatre to a temperature of 60° Fahr. prior to opening; and in warm weather the air volume can be increased and cooled by the air washer to maintain temperature conditions. The distribution of the washed and heated air is made through duct work which delivers the air into the theatre through main grilles and through smaller grilles arranged underneath the seats. The polluted air exhaust is effected through the dome by means of an exhauster fan. The whole heating and ventilating system, which was installed by Messrs. S. Mulliner & Co., Ltd., is so arranged that the air in the theatre is under a slight pressure, so that, in foggy weather, there is no risk of fog invading the auditorium.

The decision to instal town gas fired boilers at the "Capitol"



SPENCER-BONECOURT KIRKE PATENT TOWN GAS FIRED BOILER, INSTALLED AT THE WORKS OF MESSRS. J. HOPKINSON & SONS, LTD., HUDDERSFIELD. THIS BOILER HAS A NORMAL WORKING PRESSURE OF 750 LBS. PER SQ. IN.

and other London cinematograph theatres indicates that this business is well worth cultivation by gas departments.

If a gas proposition is to be really representative, the prevailing conditions must be analyzed closely, if possible in collaboration with a heating engineer. We have known of cases where the gas consumption for a gas-fired boiler has actually been based upon the catalogued duty of a cast-iron sectional boiler, regardless of whether this boiler was too large or too small. For the gas salesman there are immense potentialities in this direction for small industrial steam supplies and heating equipment. The key to the situation is just this: Every inquiry, every opening, must receive the closest analysis. The closer the investigation, the more representative and accurate the data, the better the case for the utilization of town gas.

INSTITUTION OF GAS ENGINEERS.

Programme for the Annual General Meeting, June 9 to 12.

The following is a provisional programme (subject to revision) of the Annual General Meeting, which is to be held in the Great Hall of the Institution of Civil Engineers, Great George Street, Westminster (by courtesy of the Council of that Institution), under the presidency of Mr. J. Ferguson Bell, M.Inst.C.E., General Manager and Chief Engineer to the Derby Gas Light and Coke Company.

Tuesday, June 9.

Morning: Preliminary business. Welcome of delegates from the Continent, &c. Appointment of scrutineers for election of members, associate members, and associates. Address by the President. Annual report of the Council and accounts for year 1924-25. Reports of Education Advisory Committee and the Gas Investigation Committee.

Afternoon: Paper on "The Tankless Gasholder at the Etablissements Arbel, Douai, France," by L. Rolland d'Estape, President of the Société Technique de l'Industrie du Gaz en France (Hon. Member). Discussion. Paper on "The Selection, Design, and Construction of New Carbonizing Plant at Stretford," by W. M. Carr (Member), of Stretford. Discussion.

Evening: Reception and dance at the Connaught Rooms, Great Queen Street, by invitation of the President and Mrs. Bell.

Wednesday, June 10.

Morning: Annual meeting of contributors to the Benevolent Fund. Presentation of the Birmingham Medal to Dr. Charles Carpenter, C.B.E. Reports of the Wrought Iron Tubing Committee, the Joint Refractory Materials Research Committee, the International Commission on Illumination, and the Gas Research Fellowship.

Afternoon: Paper on "Developments in Gas Calorimetry," by Prof. C. V. Boys, F.R.S. (one of the Metropolitan Gas Referees). Discussion.

Thursday, June 11.

Morning: Paper on "Town Gas for Motive Power," by Sir Dugald Clerk, K.B.E., F.R.S. (Past President). Discussion. Paper on "The Economics of Gas Production on the Thermal Basis," by George Evetts, M.Inst.C.E. (Member). Discussion. Election of honorary members. Announcement of election of President, Vice-President, and Council for 1925-26. Concluding business.

Afternoon: Alternative visits: (A) National Physical Laboratory, Teddington. (Limited to 105; ladies may attend.) (B) Fulham Works of the Gas Light and Coke Company, to view plant under course of reconstruction. (C) The Chemical and Physical Laboratories and Burner Department of the South Metropolitan Gas Company, No. 709, Old Kent Road (ladies may attend).

Friday, June 12.

Visit to Derby. (Ladies are invited.) Meet at St. Pancras, at 8.45 a.m., for special non-stop saloon train, leaving at 9.5, due Derby, L.M. & S. Railway Station, 11.37. On arrival at Derby, opportunity will be given to visit (D) the Locomotive Works of the L.M. & S. Railway and the Litchurch Gas-Works, (E) the Carriage and Wagon Works of the L.M. & S. Railway and the Litchurch Gas-Works, (F) the Gas Offices, Showrooms, and Cavendish Street Gas-Works, or (G) the Royal Crown Porcelain Works, Osmaston Road, Derby (this visit is intended for ladies only).

Luncheon in the Assembly Rooms, Market Place, by invitation of the Chairman and Directors of the Derby Gas Light and Coke Company, at 1.15 p.m., to be followed by a motor coach drive to Haddon Hall, where tea will be provided, returning to Derby by 7 o'clock for the 7.12 special non-stop saloon train back to St. Pancras, due to arrive at 9.47. Light refreshments will be available on the down journey to Derby, and dinner on the return journey to London.

The President's staff will be pleased to advise and arrange for hotel or hydro accommodation on behalf of those desirous of extending their visit beyond the Friday, upon receipt of particulars of requirements, addressed to—Mr. J. Ferguson Bell, Gas Offices, Friar Gate, Derby.

CORRESPONDENCE.

[We are not responsible for opinions expressed by Correspondents.]

Unsealed Dip-Pipe and a Simple Alarm.

Sir,—How confusing this simple physical law of relative water levels due to vacuum in the unequal and connected chambers is, is borne out by your three correspondents, as they all three are wrong. Therefore, in the interests of that young engineer mentioned in the case, I crave space in your columns.

Correspondent No. 1 ("Journal" for March 11, p. 614) says:

"This chamber is connected with another of much smaller area (viz., 4 to 1 on illustration) containing a float, so that a small variation in the water level in the first chamber is multiplied several times in the float chamber."

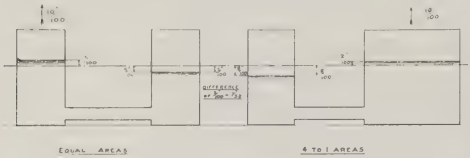
Correspondent No. 2 ("Journal" for March 18, p. 690) says:

"The motion of the float will not be multiplied by any function of the relative areas, but will be governed exactly as the pressures."

Correspondent No. 3 ("Journal" for March 25, p. 748) says:

"If the relative areas be as 4 to 1, actually there would be a magnification of the movements of the float of 1½ times."

The diagram shows two connected chambers having areas as 4 to 1,



and also two connected chambers of equal areas; and from the diagram it is easy to see that, with a fluctuation of one-tenth in the vacuum from the hydraulic mains, the descent of the float with the equal chambers will be 0·05 in., and the descent of the float with the 4 to 1 unequal chambers will be 0·08 in. Thus the increase of lift due to unequal chambers is but 0·03 in. = $\frac{3}{32}$ in., or a gain in motion of float so infinitesimally small as in no sense to warrant the adoption of unequal chambers, and so small that it totally disproves the meaning of the statement "multiplied several times."

Further, the *raison d'être* of this ingenious piece of apparatus being to increase the motion of the float, the illustration will help to show:

(1) The gain in lift for $\frac{3}{20}$ in. change of hydraulic main vacuum (*i.e.*, the stated sensitiveness of the instrument) is but $\frac{3}{8}$ in.

(2) The 1½ times increased lift stated by No. 2 correspondent should be 1¾ times.

(3) The lift of the float, if the relative areas of the chambers be increased a thousandfold, can never be doubled, to say nothing of multiplied *several* times. Floret qui Laborat.

March 26, 1925.

The Price of Coke.

Sir,—I have just received a notice from my Gas Company which informs me that they intend to increase the price of gas by an amount equivalent to approximately 10 p.ct. as and from the beginning of the Lady Day quarter. I believe this has happened, or is happening, generally. One of the reasons they advance for this increase in price is the fact that "a considerable fall in the market prices of the important residuals coke and tar has taken place."

There appears to my mind to be an enormous disproportion between the selling price of coal and that of coke. It is fairly common to find coke priced by gas companies at a figure per ton slightly in excess of that prevailing for coal in the same area. While taking into account the fact that one gets about twice the volume of coke per ton (compared with coal) there still seems to me to be an excessive charge made for material which must—from considerations of space—be regularly removed from gas-works.

Though I write as an engineer connected with a firm of contractors who do considerable business in supplying and installing coal and coke handling and gas-making plant, I fully realize there may be a flaw—of a very elementary nature—in my views. Through the medium of your columns, and by your courtesy, I therefore invite criticism on this subject, as, at the present prices, coke does not seem to me to be an attractive proposition for householders. Knowing the sliding-scale principle which is applied to gas companies' dividends, I do not suggest the threadbare charge of "profiteering."

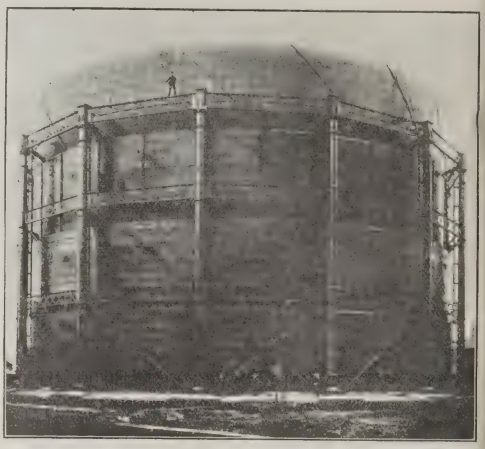
March 27, 1925. Interested.

[The foregoing letter would not have been published in the "Journal" had it not been written by an engineer connected with contractors supplying coal and coke handling and gas-making plant. The letter appears to have been instigated by a notice as to an increase in the price of gas, and by the reason attributed being the fall in the market prices of secondary products. The object of the letter appears to be to advocate lower prices for coke; and this shows a direction in which lies the interest of our correspondent. The prices that are now being charged for coke are considerably lower than they were a short time ago. We see that the Gas Light and Coke Company on the day this note is being written are advertising unbroken coke at 41s. 2d. per ton and broken at 43s. 4d. per ton, delivered free within three miles of the Company's works. This compares well with the retail price of smoke-producing coal of approximately equal calorific value. The price of coke in the gas industry is regulated by the law of supply and demand, and the demand is influenced largely by the relative values of competing fuels. We fail to understand why the gas industry should not dispose of their coke at the best price it will fetch. It would be a dereliction of duty on the part of the administrators of gas undertakings not to get as much revenue as possible from coke, seeing that the price of their primary product gas has such large dependence upon it. If a lower charge were made than that at which coke can be disposed of to-day, it follows that the difference would have to be made up by a further increase of the charge for gas. Our correspondent may rely upon gas managements regulating their coke prices so that, as far as possible, the best financial result is obtained, to the mutual interest of undertaking and gas consumers.—Ed. "G.J."]

Flying Lifts.

Sir,—We desire to call your attention, and that of the gas industry generally, to Patent No. 229,128, dated Feb. 19, 1925, by Mr. William Blakeley, for the application of the spiral system to "flying lifts" of guide-framed gasholders (new or extended), extracted in the "Journal" for March 18, p. 691.

Seeing that as far back as 1893 we successfully extended a 124 ft. diameter two-lift guide-framed holder at Rotherham to four lifts, the top or "flying" lift being on the spiral system, and that this gasholder is still in constant use, we are naturally opposing this patent.



The Flying Lift on the Rotherham Holder.

Further, we are even now approaching completion of the extension of a large holder of 2 million c.ft. capacity of two lifts to a four lift of 4 million c.ft. capacity, by the addition of one tier to the guide framing and two more lifts to the holder; the top or "flying" lift being on the spiral system. Westwood & Wrights, Ltd.

Brierley Hill, March 30, 1925.

[As far as recollection goes, our first introduction to flying lifts was in connection with the large East Greenwich holder of the South Metropolitan Gas Company in 1892, but this was not spirally guided.—Ed. "G.J."]

Explosion of Electrically-Generated Gas.

Sir,—I notice in your issue for March 25 that you refer to an explosion at Acton, which you state was caused by an explosion of gas. I think it would be well to point out to you that this explosion was not in any way connected with the gas supplied by my Company. It was caused by the fusing of a long length of electric cable, which gasified some of the bitumen coating. It was the gas generated from this that was the cause of the trouble. Coal gas or the Gas Company are not in any way concerned.

As so many of the daily papers have fallen into the error of attributing this explosion to coal gas, I would be glad if you could give publicity to the particulars now supplied. G. L. Jennings.

The Brentford Gas Company,
March 26, 1925.

PARLIAMENTARY INTELLIGENCE.

HOUSE OF LORDS.

Progress of Bills.

Reported from the Select Committee, with amendments: Horley District Gas Company (Electricity Supply) Bill and Rochdale Corporation Bill.

Select Committees have been appointed to consider the Blackpool Improvement Bill and the Oldham Corporation Bill, and will meet on Wednesday, May 6.

HOUSE OF COMMONS.

Progress of Bills.

Bolton Corporation Bill: Reported, with amendments, from the Local Legislation Committee.

Gas Regulation Act.

Copies were presented to both Houses of drafts of Special Order proposed to be made by the Board of Trade under section 10 of the Act, on the application of the Monmouth Gas and Water Works Company, Ltd.

In the House of Lords, on the motion of Viscount Peel, the draft Special Orders relating to the Biggleswade and District Gas Company, Ltd., and the Welwyn, Knebworth, and District Gas Company, Ltd., were agreed to. In the case of the latter Company, the following modifications were made:

Clause 20 (p. 9) after the words "transfer shall" insert the words "except so far as such Acts and Orders are repealed or amended and".

Clause 20 (p. 9) omit the words "continue to apply to the undertaking after that date," and insert "apply to the whole undertaking of the Welwyn Company."

Clause 44 (p. 23) after the words "Section 12 (power to purchase additional gas loads)" insert "Section 15 (amending obligations as to supply of gas)."

These Orders, together with that for the Teignmouth Urban District Council, were approved by the House of Commons, on the motion of Sir Burton Chadwick.

GAS LIGHT AND COKE COMPANY'S BILL.

HOUSE OF COMMONS COMMITTEE—Thursday, March 26.

The main provision of this Bill is to transfer the undertaking of the Brentford Gas Company to the Gas Light and Coke Company. (See "Journal" for Jan. 7, p. 30.)

Counsel for the Bill were Mr. H. P. Macmillan, K.C., Sir Lynden Macassey, K.C., Mr. W. E. Tyldesley Jones, K.C., and Mr. F. J. Wrottesley. The only petitioners appearing were the Alkali Manufacturers' Association, who were represented by Mr. W. Craig Henderson, K.C.

Other petitioners named were the London County Council and the Harrow-on-the Hill Urban District Council, but there was no appearance.

Mr. H. P. Macmillan, K.C., opening the case for the Bill, said he did not need to say much in introducing the Gas Light and Coke Company to any Committee of the House of Commons, as it was one of the best known public bodies in this country. The history of the Company, like that of many other public undertakings, had been a history of successive amalgamations and absorptions. The public interest had undoubtedly been served by the fact that gas could be supplied more cheaply when manufactured in bulk. Between 1870 and 1922 no fewer than eleven undertakings had been merged in the main Company, which now supplied about 950,000 consumers. The total capital at present was approximately £20,763,000, and the dividends were regulated by the sliding-scale.

The main purpose of the present Bill was to obtain the sanction of Parliament to the transfer of the Brentford Company to the Gas Light and Coke Company, under the terms of an agreement entered into between the parties on July 25, 1924. The agreement had been approved by both Companies, and everything, therefore, was in order. Though the area proposed to be incorporated was large in extent, it was, in parts, different in character from the other territory of the Gas Light and Coke Company.

The proposals of the Bill had been subjected to the most searching scrutiny on the part of the numerous local authorities concerned. There were no less than 35 petitioners against the measure originally, but Mr. Craig Henderson, K.C., was the sole survivor of that large—he must not say that motley—army. Great local interests were involved, and the local authorities concerned had deposited their petitions for the purpose of watching the progress of the Bill and seeing that appropriate clauses were adjusted. They were all, in effect, satisfied, as was apparent from the small list of appearances before the Committee. The Bill had survived an unusual amount of scrutiny. Accordingly, no one appeared to challenge the expediency, in the public interest, of the amalgamation. The terms as between the shareholders and debenture holders of the two Companies were satisfactory to them and were embodied in the Bill; and the only point to be determined by the Committee was that raised by the Alkali Manufacturers' Association, relating to the clauses applying the provisions of the Gas Light and Coke Company's Acts and Orders to the limits of supply as extended by the Bill, repealing certain enactments of the Brentford Company, and transferring to the Gas Light Company the unrepealed enactments. The Brentford Company, said Counsel, had its own series of Acts and Orders, but now that it was to be merged in the undertaking of the Gas Light Company, the consolidation of the two systems must be effected, and the Brentford Company had to be brought within the code of the Gas Light Company in order to produce a uniform code operating throughout the whole district. The clauses in question provided that the existing code of the Gas Light Company should, immediately after the transfer, become applicable to the extended sphere of the Company. The enactments of the Brentford Company to be repealed were set out in a schedule to the Bill. One of the sections of the Brentford Gas Order of 1924, part of which it was proposed to repeal, was section 37, which gave power to use lands for the manufacture and storage of gas. The Alkali Manufacturers' Association asked the Committee to save from repeal sub-section (2) of that section which the Bill proposed should be repealed, and to make it part of the code of the Gas Light Company in so far as it affected the district of the Brentford Company.

Section 37 (2) of the Brentford Order of 1924 is as follows:

"The Brentford Company may also:

"(A) Purchase the residual products arising from the manufacture of gas by other gas undertakers and (on any lands upon which the Brentford Company are for the time being authorized to work-up and convert their own residual products) work-up and convert such purchased residual products, and therewith manufacture other products of the same kind as the Brentford Company are manufacturing from their own residual products. Provided that the quantity of any residual product so purchased by the Brentford Company in any year shall not exceed one-third of the quantity of the like residual product which shall in that year arise directly or indirectly from the manufacture of gas by them; and

"(B) purchase from other gas undertakers and elsewhere, and use, the materials required to work-up and convert the residual products so arising from their own manufacture of gas, or purchased as aforesaid.

"But the Brentford Company shall not manufacture chemicals exclusively from raw materials purchased from sources other than gas undertakings, or in the manufacture of which the use of residual products produced by the Brentford Company or purchased from other gas undertakings is merely subsidiary."

The request of the Alkali Manufacturers' Association, said Counsel, was founded upon a complete misapprehension of the situation. So far as the Gas Light and Coke Company were concerned, they did not want any power, either in themselves or in the Brentford Company after they had taken that over, to purchase residuals from anybody else, because it was not the practice of the Gas Light Company to buy residuals from other undertakings; nor had they the power to do so, except that they could buy residuals for working-up their own residuals.

Speaking of the controversy which had existed as to whether it was right and proper for gas undertakers to buy residuals from other gas undertakers, Counsel said that the operations of gas undertakings had been very jealously watched by the heavy chemical trade, who considered that the gas undertakers were to some extent poaching on their preserves, because they were dealing with the working-up of materials into marketable products. The genesis of this practice of purchasing residuals not produced in the undertaking itself was that in small works it did not pay to set up a plant to work-up these residuals and to dispose of them; and the practice had grown of collecting residuals from a number of gas plants. Exception was taken, however, by the Alkali Manufacturers' Association to any gas undertaking handling more than its own residuals. The Association had sought to have every undertaking working in a water-tight compartment, which was a very serious restriction upon small undertakings, and, in effect, would have prevented them from disposing economically of their residuals. Counsel then referred to a number of Bills before Parliament before 1912 in which gas undertakers sought powers to purchase residuals from other gas concerns. This had aroused the vigilance of the Alkali Manufacturers' Association, and in the result a Joint Committee of both Houses of Parliament in 1912 had considered the trend of legislation on this question. The outcome of the inquiry by this Committee was that, where power was given to purchase residuals from other gas undertakers, this power should be limited to one-third of the amount produced by the purchasing undertaker. That restriction was placed upon the Brentford Company under their Order of 1924.

Why the Alkali Manufacturers' Association wanted that power retained by the Gas Light Company, in so far as the Brentford area was concerned, he did not know. The Gas Light Company had not that power in their present area. For some reason, the Association were trying to force upon the Company a power they did not want; but it was not the practice of Parliament to do this.

Until 1924, when the Brentford Company purchased the Harrow and the Richmond Gas Companies, the Brentford Company had unlimited powers to purchase residuals from other undertakers; but in 1924 that power was limited to one-third of the amount manufactured by themselves, on the representation of the Alkali Manufacturers' Association. The Gas Light and Coke Company resented the present suggestion that this power should be retained in so far as the Brentford area was concerned when they did not want it. In the first place, it was inconsistent with the policy of the Gas Light and Coke Company in the past. In 1922 they had taken over the undertaking of the Ilford Gas Company, who had powers to purchase residuals up to one-third; but this power was repealed when it was merged in the Gas Light and Coke Company. Again, if the power was retained in respect of the Brentford area, it would be difficult to work, because the Brentford output of residuals would have lost its identity completely when the area was taken over. It was part of the advantages of these amalgamations that the gas would be made at the most convenient place, and the gas supplied in the Brentford area would not necessarily be made in that area. How could it be said, therefore, what proportion of the total residuals represented the Brentford residuals? The Gas Light and Coke Company did not want a differential code applying to any part of its area.

Asked whether it would not be the same thing if the Gas Light and Coke Company accepted the power, but did not use it, Counsel reiterated that it would produce confusion in the Company's code. The logical course was that, if the Committee sanctioned the amalgamation, it should be sanctioned on the basis that the Brentford undertaking came into the code of the Gas Light Company.

Continuing, Counsel said that the Alkali Manufacturers were

naturally not really anxious that the Company should have power to purchase residuals from other undertakings, but were more interested in the proviso, which stated that the Brentford Company should not manufacture chemicals exclusively from raw materials purchased from sources other than gas undertakings, or in the manufacture of which the use of residual products produced by the Company or purchased from other gas undertakings was merely subsidiary. He believed that what the alkali manufacturers really wanted to do was to have that proviso edged into the constitution of the Gas Light Company, to whom it did not apply at the moment. It was merely stated in the petition that the clause should be preserved, with its restriction; but as the proposal of the Bill was that the clause should be repealed, in order to bring the Brentford undertaking within the general code of the Gas Light Company, the alkali manufacturers could not object. They had failed to disclose any manner in which they would be injuriously affected. In looking around for a reason as to why they had put this petition forward, he said he remembered that the Alkali Manufacturers' Association were at present in litigation with the Gas Light and Coke Company, and he could only surmise that that litigation and the present proceedings had a connection. Mr. Deuchar, the Secretary of the Castner-Kellner Company (who were members of the Alkali Manufacturers' Association), had bought shares in the Gas Light and Coke Company in order to bring litigation against them, and this litigation was started for the purpose of stopping the Company making caustic soda for the purpose of working-up their own residuals. The High Court and the Court of Appeal had both held that the Company had power to make caustic soda, but only for the purpose of working-up their own residuals; and the matter had been taken to the House of Lords. It seemed to him, therefore, that this petition was possibly deposited with a desire to obtain an advantage in connection with that litigation. The purpose of the Alkali Manufacturers' Association was to impose upon the Gas Light Company the proviso already mentioned, the meaning of which was that the Company should not encroach upon the chemical trade at large.

Mr. *D. Milne Watson* (Governor of the Gas Light and Coke Company) gave evidence, and said that the terms of the Bill were satisfactory to all concerned. The Gas Light and Coke Company had no wish to purchase residuals from outside. They had already sufficient supplies of their own; and further, he had been advised that in law the Company had no power to do so. The power to purchase from outside was absolutely foreign to the code on which the Company had carried on business; and it would be embarrassing to them, inasmuch as, after the amalgamation, the gas flowed from the various works in all directions. The gas supplied in Brentford would not necessarily be made in Brentford, and they could not differentiate between the Brentford part of the business and the remainder.

Asked by a member of the Committee how the Company would be embarrassed if they had the power but did not use it, Mr. Milne Watson admitted that, if the Company accepted the clause, it would have the effect of reducing their powers in another direction. The Company had spent large sums of money on the faith of the powers granted them by Parliament, and those powers had been upheld in the Law Courts. If the restriction contained in the clause in question was placed upon the Company, they would find it embarrassing in carrying on the businesses they were at present entitled to carry on. The proviso which would preclude the Company from manufacturing chemicals exclusively from raw materials purchased from sources other than gas undertakings would prevent the Company manufacturing caustic soda used for working-up their residuals.

Mr. Macmillan, in the course of his examination of Mr. Milne Watson, said that, if the Alkali Manufacturers' Association had said that they wanted to retain the advantage embodied in the proviso referred to, they should have treated the Committee with candour. It was apparently hoped, he supposed, that the members of the Committee, in their simplicity—if he might say so—would be induced to put a clause into the Bill which would give the Alkali Manufacturers an advantage entirely remote from what had been disclosed. This was not the way to treat any Parliamentary Committee, or Parliament, and he suggested that the reward of the Alkali Manufacturers should be that they should be driven from the seat of judgment.

Witness, replying to Mr. Craig Henderson, who cross-examined, agreed that the Company had power to purchase materials for working-up their own residuals elsewhere than from other gas undertakings; and he wished to retain this power.

Counsel pointed out that the clause at present applying to the Brentford area gave power to purchase from other gas undertakings and elsewhere materials required to convert their own residuals. Counsel then classified residuals into three groups: (1) Ammoniacal liquor; (2) tar; and (3) spent oxide. These were used in the manufacture of chemicals: and what had given rise to the dispute in 1912 was that the chemical manufacturers of the country had to look to gas undertakings mainly for their raw materials.

Witness said that if Counsel put it in this way, he might point out that, as the gas companies purchased the coal, and the bye-products came from the gas undertaking, he had always failed to see that there was an inherent right to any outside party to say that the gas companies should hand over these products for that outside party to deal in.

Counsel said that Parliament had imposed these restrictions. The gas companies were granted monopolies over large areas for the supply of gas, and were created to manufacture and supply gas in their areas. He referred to residuals as a "happy accident" in the manufacture of gas.

Witness would not accept this, and said he believed that the original object of the gas companies was to recover the bye-products. There had followed the use of gas, which had ultimately become the more important.

Counsel said that the main object was to supply gas to the community, and if the main object were the supply of chemicals there would be no reason for a monopoly.

Witness replied that when the gas industry first started there was no monopoly, and companies were operating in competition: but, owing to the difficulties resulting in connection with the pulling-up of streets, &c., monopolies were granted.

In the course of further discussion, Counsel said it had been admitted in the past that the Gas Light and Coke Company had bought residuals from other companies, and, therefore, those purchases were illegal. Mr. Milne Watson admitted that it had been done some years ago, but on a very small scale, and it had now been ascertained definitely that there was no power. It was not done at present.

Mr. Macmillan said that a legal opinion had been obtained; and the statement of the advisers was: "We do not think the Company have any power to purchase the residuals of other gas undertakers except in so far as the materials purchased may be required for the purpose of working-up the residuals resulting from the Gas Company's own manufacture of gas."

Mr. Craig Henderson said that, whatever the powers of the Company might be, which had up to now been exercised within their area, they were now seeking to apply them to the Brentford area. This meant a very considerable addition to the area of supply.

Mr. *Milne Watson* said it was a considerable addition of green fields.

Counsel said it was a territory ripe for development, with some rare and refreshing fruit for the Gas Company, and in due time they hoped to get it. He understood the case was that, merely because the absorbing company happened to be the Gas Light and Coke Company, the rights within the Brentford territory should be increased by Parliament.

Witness replied that, if the clause as it stood were applied to the Company, it would give them the right to purchase more residuals so far as the Brentford area was concerned. But he did not want this power, and, therefore, he was a friend of the alkali manufacturers.

Mr. Craig Henderson then pointed out that, while in the Bill various Brentford enactments were expressly repealed, there was saved from repeal a clause in the Brentford Order of 1881 which gave the Brentford Company unlimited power to purchase residuals.

Mr. F. J. Wrottesley (for the promoters) said that, if this were the case, he was not aware of it; and it was certainly not intended. If there was any doubt about it, it would be made clear. It had not been mentioned in the petition, however.

Answering further questions, Mr. Milne Watson said that the Gas Light and Coke Company did manufacture chemicals exclusively from raw materials purchased from sources other than gas undertakings, but to a limited extent. They only manufactured such quantities as they needed. They had also manufactured chemicals in the manufacture of which the use of residual products was merely subsidiary, to a limited extent; but he was informed that at the present moment they were not manufacturing anything.

Asked if the clause in question had not been inserted in nearly all the Acts passed by Parliament since 1914, Mr. Milne Watson would not admit this. It had, he said, been put in some. He considered it wrong that a Company who were only carrying on their own work should be asked to give up their powers in part of their district.

This concluded the evidence.

Mr. Wrottesley, at this point, said it was right that the 1881 Order of the Brentford Company contained a clause enabling them to "deal in" coal tar products and various other products. It was necessary to retain the operative part of this clause, however, because its object was to enable the Company to use certain lands for gas manufacture. It had not been realized that the power to "deal in" residuals remained; but he would undertake that those words and words of a similar kind would be deleted.

Mr. Craig Henderson, addressing the Committee, said that the Gas Light and Coke Company had been fortunate enough to obtain powers of a fairly wide character, which had enabled them to carry on an extensive manufacture of chemicals for converting their own residual products. If the Company were coming to Parliament to-day for the first time, in order to get powers, they would not be in the happy position they were in in 1868, when they obtained their consolidating Act. They would have to face the fact that ever since 1912 there had been followed the declared policy of Parliament, that restrictions should be placed upon gas companies, so that, being protected under a statutory monopoly, and having great advantages with regard to the supply of gas, they should not at the same time become competitors with other people outside who had not a monopoly of that character. As to the position of the Brentford Company, he said that only a year ago they were a smaller undertaking than at present. Last year the Company had absorbed the Harrow and the Richmond Companies, and, as the result of opposition by the Alkali Manufacturers' Association, they had had imposed upon them the model clause. Thus, only twelve months ago, this restriction, which was the declared policy of Parliament, was made to apply to this area. The Gas Light and Coke Company now came to Parliament for sanction to an agreement to absorb the Brentford Company, and, having obtained their powers under an old Act, had asked that they should be given the Brentford area free from the restrictions which Parliament had imposed upon them. Why should Parliament do this? Why could not the Gas Light and Coke Company take the Brentford area as it was? It was said that the Company had no power to purchase residuals from other gas undertakers except for the purpose of converting their own residuals; but this was a very wide power. The Company's output of gas and of residuals was enormous, and it had a huge chemical undertaking quite apart from gas supply. If there would be any difficulty, as was suggested, in working one part of the amalgamated area with another, the one part being subject to a restriction not applying to the other, then this was a very good reason for not allowing the amalgamation. Having regard to the whole of the legislation upon the subject, if the Gas Light and Coke Company were to have powers in the Brentford area extended beyond what the Brentford Company had, they should be required to prove to the Committee a very strong case. The only thing that handicapped the Company by the application of the clause in question was the proviso at the end. This, however, did not apply to the existing area of the Gas Light and Coke Company, but only to the Brentford area—the rich territory which was to be added to the Company's present area. He asked the Committee not to depart from what had been the declared policy of Parliament.

As the result of questions put by the Chairman of the Committee with regard to what happened when the Gas Light and Coke Com-

pany took over the undertaking of the Ilford Gas Company, Mr. Wrottesley handed in copies of the Ilford Gas Order of 1920, and the Gas Light and Coke Company's Order of 1922. The latter repealed the Ilford Gas Order of 1920, except the schedule and so much of section 31 as related to the lands described in that schedule—in other words, so much as allowed the manufacture of gas on those lands. This was exactly what the Gas Light and Coke Company asked the Committee to do in this case.

Mr. Craig Henderson asked if there were opposition in the Ilford case.

Sir Lynden Macassey replied that, however that might be, it represented the policy of Parliament.

After deliberating in private, the Committee decided to pass the preamble of the Bill.

Monday, March 30.

The clauses of the Bill, as amended, were approved by the Committee. In accordance with the statement made by Counsel for the Company during the proceedings on Thursday, a clause was inserted to make it clear that nothing in the Bill should confer any further powers upon the Company with regard to residuals. Originally there were clauses in the Bill enabling the Company to supply power gas (see "Journal" for Jan. 7, p. 30), but these have been withdrawn by agreement between the Company and the various local authorities. There are protection clauses in favour of the London County Council, with regard to streets and buildings; the Metropolitan Water Board, relating to the protection of their apparatus; and the Harrow-on-the-Hill Urban District Council, relating to the closing of a footpath. These clauses are in the ordinary form.

HORLEY DISTRICT GAS (ELECTRICITY SUPPLY) BILL.

(*Continued from p.* 750.)

Friday, March 20.

Mr. Tyldesley Jones, cross-examining Mr. Broadberry, said that what was called waste heat was not really waste heat, because in up-to-date works it was utilized for the purposes of the works. He put it to witness that in up-to-date gas-works, where the proper appliances had been installed, there was no more heat generated than was required by the gas-works for its own purposes.

Witness admitted that this was probably correct. There would likely be some spare power after satisfying the demands of the works, but it would not amount to a great deal. As to the Horley Works, he said they were comparatively small, but he would not admit that they were out-of-date. For a works of their size, they were efficient. He agreed that the Company had not utilized the waste heat in their works up to the present time, and admitted that this would make a difference in the cost of production of gas, but not a very material one.

Counsel suggested that the present proposal to utilize the waste heat was rather belated. Coming to the statement made by Mr. Broadberry on the previous day, that the Tottenham District Light, Heat and Power Company had supplied electricity in Wood Green at a price comparable with that charged by the North Metropolitan Electric Power Supply Company, and by the Borough of Hornsey (who were supplying in adjoining areas), he referred to the London County Council statistics of the electrical undertakings of London, showing the costs of generation and the prices charged by these three undertakings, and pointed out that the cost of, and charges for, electricity were lower in 1921, 1922, and 1923, in the case of the North Metropolitan Company and the Borough of Hornsey, than in the case of the Tottenham Company, though the two former undertakings were separate electricity undertakings, and in the latter case the Company supplied both gas and electricity.

Witness said that what he wanted to point out was that Wood Green was a case in which no independent company could have carried out the public supply of electricity to the same advantage as it had been carried out under the fostering care of the Gas Company.

Counsel said the figures did not prove this.

Witness replied that he thought they did.

Counsel maintained that the figures showed exactly the contrary. Coming to the statement that, in a general sense, gas represented heat, and electricity represented light, he said that this showed the attitude of a gas company towards electricity supply. He went on to ask if it had not been put before Parliament over and over again that, if the electricity undertakings could develop a day load, by increasing its use for power purposes, they would be able to develop electricity for lighting purposes far more cheaply than if the machinery at the power stations were used only during the short lighting period; it was only by doing their utmost to develop the use of electricity for power during the day that they could hope to cheapen the price of electricity for lighting at night.

Witness said that might be so; but God help the electricity companies if ever they got the cooking load!

In answer to further questions, witness said that a considerable amount of electricity was used for cooking purposes, but there were very few electric cookers in use anywhere around North London. Asked why, he said it was because it was so much cheaper and more beneficial to cook by gas. Electricity could not compete with gas for cooking purposes. He regarded small industrial power purposes, however, as being a suitable application for electricity. Asked if, assuming there were a demand in Horley for electric power for small machinery, electricity would be more suitable for it than gas, he said that in all probability it would, especially if the machinery had to be used intermittently.

Counsel said that the views of the Horley Gas Company were exactly the opposite to that. He quoted from a letter written to the Reigate Rural District Council on Jan. 5, 1925, in which it was stated that the obvious conclusion to be drawn from the long lists of precedents was that Parliament in its wisdom considered that any possible competition, which was the only argument for separate control, between a gas company and an electricity company, was nowadays really negligible. He asked witness whether he agreed that competition between gas and electricity companies to-day was almost negligible.

Witness would not say it was negligible; the two industries were going ahead side by side.

Counsel said that competitors generally ran side by side until one of them got ahead.

Witness replied that gas had been ahead for a long time.

Counsel: And you mean to keep it ahead by every possible means.

Witness did not agree.

Counsel said that the letter referred to went on to state that the competition was negligible for the reason that by far the greater and ever-increasing proportion—in the Horley case 60 p.ct.—of the total output of gas was used for cooking and for domestic heating and small power purposes, in which kind of service electricity, in a district such as Horley, could never compete with gas. He asked if witness agreed with that.

Witness replied that he did not agree so far as small power units were concerned, especially if used intermittently.

Dealing with statements which had been made that, if competition between gas and electricity undertakings were eliminated, economies would result, Counsel ascertained that the number of units supplied per head of population in Wood Green in 1924 was 20; and witness agreed with him that towns of the same size as Wood Green had an average consumption of 50 units per head, where two competing undertakings were operating. Counsel went on to say that the average consumption per head in England was 200, but it was only fair to say that this included large industrial districts, where an enormous amount of electrical energy was used for power, traction, and so on.

Witness said there was no demand for large power purposes in Wood Green, but the consumption per head would reach 50 units before long.

Mr. *G. M. Gill* (Consulting Engineer) said there were considerable advantages arising from the placing of the supply of gas and electricity in the hands of the one concern in a small district such as Horley. Enumerating some of these advantages, he said that it was possible to put down electrical plant in the gas-works and so avoid the necessity for procuring a new site. Horley Gas-Works had a railway siding, and this was somewhat difficult to get on a new site. There would also be a saving in rates and taxes, and there would be common offices, transport facilities, a common weighbridge, workshops, &c. There were also advantages on the administrative side, because the Directors, the managing staff, clerks, collectors, canvassers, mechanics, storekeepers, and so on, would be able to attend to the two organizations.

With regard to the statement made by Mr. Tyldesley Jones that there was scope for the use of all the power that could be generated from waste heat at the gas-works themselves, witness said that the Horley Works were small, and a works of that size did not employ power to anything like the extent that a large works would. For instance, at Horley there were no stoking machines or coal and coke handling plant, and this was a general state of affairs in works of that size. In a small works the waste heat would be available for external purposes, and in a large works a great deal of it could be used for internal purposes. As to the condition of the Horley Works, it was a very fair average for works of that size; he had inspected the works, and had seen nothing which he would have condemned. The amount of waste heat at Horley was about the same as would be found at other works of that size. In the winter months there was an amount of waste heat which should generate something over 900 lbs. of steam per hour. The temperature of the waste gases at the point where they would enter the waste-heat boiler was something over 500° C. Answering further questions on the point of competition, he said it was not good for the consumers in a small district such as Horley. Elsewhere it was, up to a point; there were advantages on both sides.

Mr. Tyldesley Jones suggested that, before electricity was used for lighting, there was no attempt by the gas companies to substitute the incandescent burner for the old flat-flame burner, and said that it was after the introduction of electric lighting, and in consequence of competition, that the improved methods in the gas industry were introduced.

Witness had his doubts.

Counsel said that, whatever might be the future policy of the gas and electrical industries, whatever combinations might come about, the consumer had benefited very materially indeed from the competition which had of late years existed between gas and electricity; and, had it not been for the advent of electricity, the gas industry might not have been in the proud position it occupied to-day.

Witness would not go so far as that.

Counsel, with regard to the utilization of waste heat in small gas-works, said that there were installed in small works to-day, by up-to-date gas engineers, many of the appliances which witness had said were only used in large works.

Witness said there was a sprinkling of small works in which there were mechanical stokers, for instance, and agreed that there was a tendency to apply more and more labour-saving appliances in small works.

Counsel suggested that the reason why there were many small works which had not these appliances was that those works were out-of-date. Other plants which he suggested could utilize waste heat were the sulphate plant and water gas plant. He then asked whether witness knew of a single works of the size of the Horley Works where there was a surplus of waste heat beyond what was wanted for a waste-heat plant.

Witness said it was much better practice for a works of that size to go on supplying its steam from its present boiler plant, and to use the waste heat for the production of electricity. In this way they could use up the coke breeze and the fuel extracted from the furnace ashes for producing steam. It was better to make steam with that fuel than to try to sell it. If they were to shut-down the old boiler plant at Horley, and run the works with the steam generated by a waste-heat boiler, he did not think they would use it all. Asked what proportion there would be available, he said there would probably

be half of it. Waste-heat boilers, he said, were comparatively new. Asked if it would be fair to say that in the last five or six years it was proper gas engineering practice to adopt them wherever possible, he replied that it was so in the larger works, but not in smaller ones in all cases. If electricity were not generated by steam from waste heat at the Horley Works, he admitted that it might be a good thing to utilize waste heat for the works purposes.

Counsel then suggested that the water gas plant, if worked in this way, would require 50 p.c. of the whole production of heat.

Witness said he had not worked this out. In re-examination, he stated that 900 lbs. of steam per hour could be generated from waste heat when the amount of coal carbonized was 18 tons per day.

Mr. Hugh Seabrook's Evidence.

Mr. *A. Hugh Seabrook* (Sir Charles Bright & Partners, Ltd., Electrical Engineers, and late General Manager and Chief Engineer to the St. Marylebone and West Ham electricity supply undertakings) gave evidence as to the electrical scheme, which had been prepared by Mr. F. A. Greene (Consulting Electrical Engineer), and which he himself approved. In the first instance, he said, he was retained, in conjunction with Mr. Gill, for the purpose of advising the Company solely on the question of the utilization of waste heat for the generation of electricity. The difficulty they were confronted with was that the recovery of gas-works "surplus" heat (this was a better term than "waste" heat) was comparatively new, and very few engineers had had the advantage of being associated with the work. There were a number of eminent engineers to-day who would more or less scoff at the suggestion that gas-works produced surplus heat which would be of any use whatever for the production of electrical energy. It had been referred to by some well-known men as a "stunt"; but he wanted the Committee to realize that it was very far from being a stunt. The experience of one gas company had induced them to extend largely the principle of surplus heat recovery. Two or three other works of the company were now being equipped with this plant, and their biggest works were putting-down a 2000-kw. plant; the whole of the steam used being produced by surplus-heat boilers. At present, the company in question were considering the cost of converting the surplus heat, and of disposing of it to outside users of electricity. One or two big undertakings had experimented, and were prepared to spend a considerable capital sum in proving the idea. The small undertakings, naturally, had not the financial resources, and had to wait for the results obtained by others. There was no question that the recovery of surplus heat had been carried out with marked success. At present it was being recovered chiefly from the carbonizing process, but it was being examined in other directions, and, in fact, a Continental engineering firm would now put down plant and guarantee the results, utilizing another form of surplus heat in gas-works—namely, the heat generated by coke quenching. Much valuable heat could be recovered from this additional source, which, so far as this country was concerned, had not even been touched. The firm mentioned was Messrs. Sulzer Bros., of Germany. Another important aspect of this question was that it worked towards the conservation of coal. One large gas company would be able to release about 100,000 tons of coke breeze per annum, which was now being used on their boilers. This 100,000 tons of coke breeze would be available, when the plant was completed, for use by other fuel-consuming companies. It was a simple matter to deduce roughly the result if this heat recovery were applied to every gas undertaking throughout the country. Coming to the Horley Gas Company's electricity scheme, witness handed in a table giving the estimated results of the first two financial years' working. It had been decided to instal alternating current at 240 volts, single phase. In a place such as Horley, single phase would be cheaper and better than three-phase, the latter being more suitable where there was a demand for power. In Horley the proposition was a thin one for the first few years, but it was hoped that it would develop. In the first year he estimated that the units generated would be 70,000, and the units sold, 53,000; losses in transmission accounting for the difference. The maximum demand expected was 50 kw., the load factor 12 p.c., and the number of consumers 150. The Gas Company, having been in the neighbourhood for 30 or 40 years, were more likely to get consumers than were a new concern, because they had local influence and valuable knowledge. The gross income from current and meter rents was estimated at £1965, and the average price obtained per unit 8·6d. (10d. for lighting and 3d. for power). The expenditure, for generation, depreciation, rents, rates, and taxes, management and administration, was estimated at £1433, or 6·5od. per unit. During the first year, three-quarters of the units supplied could be produced from an engine run by the surplus heat plant, and the remaining quarter by an internal combustion engine, gas or oil driven. Thus the fuel costs to the Company would be reduced by three-quarters, whereas a separate company would have to use fuel to generate the whole. The cost of actual generation was £373 for the 70,000 units, £300 of that representing cost of wages, repairs, and maintenance, and the £73 representing the cost of the fuel to generate one-quarter of the output (17,500 units), at 1d. per unit. The net profit for the year was estimated at £532. In the second year he estimated 110,000 units generated, and 87,000 sold; the maximum demand being 75 kw., the load factor 13·5 p.c., and the number of consumers 200. This represented a normal increase. Only two-thirds of the units generated would be produced by waste heat, and one-third would be produced by fuel. The income was estimated at £2820 for current and meter rents; the average price obtained for current being 7·5d. per unit. As to generation, the wages, maintenance, and repairs would amount to £400, and the cost of fuel for one-third of the output, £152, making £552. The total expenditure would be £1852, equal to 5·13d. per unit; leaving a net profit of £968. It had been found, said witness, that where gas and electricity supplies were combined, the gas consumption increased rather more rapidly than previously, though there was apparently no competition. It was difficult to explain why, but it was a fact. He had assumed that in the second year of the electricity supply the amount of waste heat available from the gas-works would be the same as in the first year, but if the consumption of gas increased, the amount of waste heat would increase, and the Company would be able to generate more than two-thirds of the output of electricity by the utilization of this heat. As to capital expenditure, the amount on generating plant in the first year, including surplus-heat recovery plant, would be £4770, and the expenditure on mains £8813, making a total of £13,583. In the second year the capital expenditure would have reached £6270 on plant, and £10,000 on mains, making £16,270. With regard to the suggestion that the Gas Company sought electricity powers in order to prevent competition with the gas undertaking, he said this had not been substantiated. He had been associated with two gas companies who had promoted electricity Bills. These Bills received Royal Assent in August, 1923, and in both cases the generating stations were opened by August, 1924. There was no object in spending a lot of money and letting it lie idle. He looked at the matter purely from the commercial point of view, and was not prejudiced.

Mr. Tyldesley Jones, cross-examining, referred to a paper read by Mr. Seabrook before the London and Southern Junior Gas Association on this subject, on Jan. 27, 1922 (see "Journal" for Feb. 1, 1922, p. 259), in which he had said "My proposal to combine gas and electricity stations can easily be damned by the engineer, gas or electrical, who does not like the idea." Counsel suggested there had been a good deal of damnation of the idea, and witness agreed. In the reply to the discussion, witness had said that Mr. S. B. Chandler (of the South Suburban Gas Company) had touched on the weakest spot in the whole thing—that was the danger of what the Americans called "combination in restraint of trade." Thus even the witness had to admit that, delightful as was the idea from the point of view of the engineer, there was a weakness in that combination possibly in restraint of trade.

Having ascertained from witness that the only power uses which he had in mind at Horley when arriving at his estimates were domestic, Counsel asked if there were any laundries in the district, and suggested that they were good customers for electric power. Witness replied that he believed he had seen one laundry, but considered 3d. per unit too high to be attractive in that case. Counsel thereupon suggested that the Company might cut the price for power very fine, in order to secure a power load, and then secure the lighting of the laundry; but witness regarded that as an unbusinesslike proceeding. Counsel pointed out that witness had taken charge of the St. Marylebone Borough Council's electricity supply undertaking at a time when it was saddled with a big debt, but had built-up the business and made it a paying concern, and had had to cut prices very fine for some years in order to do this. Witness agreed, but said that one must take into account the difference in the kind of residents in St. Marylebone and Horley. He agreed that it was his experience that in districts such as Horley, where many houses had their own electric generating plant, those plants were shut-down as soon as a public supply of electricity became available.

With regard to the estimated cost of generation, Counsel pointed out that, though it was intended to take away from the gas undertaking for the purposes of the electricity undertaking the waste heat which, if used in the gas-works, would reduce the cost of making gas, nothing had been allowed the gas undertaking in this respect. Witness replied that the gas undertaking would not be really any worse off by the utilization of the heat, which was at present waste. There was a good deal of rubbish in the way of fuel generally used in gas-works boilers for the production of the small amount of steam required; and in a case such as the Horley undertaking that fuel could not be disposed of otherwise. The average small gas company found that the steam raised by the use of this waste fuel was sufficient for their purposes, and they did not recover surplus heat, because, until they were able to supply electricity, they had no use for it. No one in his senses would instal mechanical conveyors and machinery of that type in a works of this size.

Discussing stand-by plant, Counsel asked what happened if the 50 kw. alternator to be installed broke down. Witness replied that if it broke down outside the winter months it would not have any effect on the supply, but if it broke down completely in the winter months he would have to replace it, and the demand could not be met in the meantime. He had allowed for all the plant usually installed in a small undertaking, where they could not afford to duplicate expensive plant. Counsel asked if it were not an absolute axiom of all electrical engineers that they must have, as spare plant, a unit of the size of the largest unit. Witness did not agree in the case of small stations, but in important stations it was so. In small stations they had to run certain risks. Counsel retorted that that was not very cheery for his clients, who were residents of Horley.

With regard to capital expenditure, Counsel ascertained that, though part of the gas-works site would be used for the erection of the generating station, no allowance had been debited to the electricity undertaking in respect of this. Witness did not see anything wrong in this, and, when asked whether the gas undertaking could not sell that land if it did not intend to use it for gas-works purposes, he said that it was of no value in the middle of a gas-works site, and could not be sold. Counsel said that, when the generating station was being erected, the coke store would be farther from the gas-works, and the cost of transporting it would be greater for the gas undertaking; but witness thought that this would make no appreciable difference. Counsel, examining a plan which he had not seen before, said the site was overcrowded, and that there was not sufficient space even now to devote to the development of the gas-works. Witness differed. The site comprised two acres.

Finally, Counsel pointed out that nothing had been allowed in the estimates put in for the costs of the present Bill, and wondered whether that was to be debited to the gas undertaking.

Re-examined, witness said that if an undertaking were overloaded financially by the installation of spare plant to ensure against every possible accident, it was not business. The combination of electricity undertakings with existing gas undertakings was the only way in which to get electricity into districts with a small population, and, at the same time, to produce reasonable remuneration on the capital. There were a number of small electricity companies which had never paid a dividend, and were not likely to, and it was not sound to put money into a business if it were not going to earn money.

Major *D. Napier-Whittingham* (Acting Managing Director of the Sussex Electricity Supply Company, Ltd.) gave evidence to the effect that his Company were desirous of obtaining a bulk supply of elec-

tricity from the Horley Gas Company, because, if it were not obtainable, they would themselves have to expend considerable capital on new plant.

Cross-examined by Mr. Tyldesley Jones, who suggested that it would not matter whether the bulk supply came from the Gas Company or from the Horley Electricity Company, witness said he would prefer it from a long-established Company which he knew to be sound financially. He did not reply when asked whether he would like it from an undertaking which would have to shut-down if an engine broke down.

Monday, March 23.

Mr. *H. J. Randall* (a Director of the Horley District Gas Company, and Engineer and Manager of the Yorktown and Blackwater Gas and Electricity Company) in evidence said that in the autumn of 1922 the Directors of the Horley Gas Company were considering the question of getting electricity powers, and in November of that year had written to the Gas Companies' Protection Association for advice. The Secretary of the Association had advised them that the two courses open to them were to promote a late Bill in Parliament in the 1923 session, or for the Directors to promote a Special Order under the Electric Lighting Acts, with a view ultimately to transferring the powers to the Company when they got the necessary sanction from Parliament. They had at first decided to adopt the second course, but, on the advice of their solicitors, had ultimately deferred action, owing to the possibility of the passage of the Bill introduced by Mr. R. G. Clarry, M.P., to give statutory gas companies facilities for obtaining electric supply Orders from the Electricity Commissioners, instead of having to go to Parliament for power. He corroborated the statement made by Sir Harry Courthope-Munroe with regard to the events leading up to the promotion of the present Bill. He considered that a gas company, under ordinary conditions, should be able to distribute electricity in an economic way, and pointed to the economies arising from the combination of the two undertakings. This was particularly the case in such a district as Horley, where the greater part of the load was for lighting, and was almost negligible in the summer. The idea of using waste-heat plant for generating electricity was that, through the hours of the night, after the load had dropped, and also during the day when there was not a large demand, the waste-heat plant could be used, and when the demand increased, the auxiliary gas or oil driven plant would be used. Dealing with the experience of the Yorktown and Blackwater Gas and Electricity Company, he said that the demand for electricity had increased steadily since 1921, and the gas load had also increased. His figures showed that in 1922 the Company had sold 23,701 units, and in 1924, 75,970. In 1922 and 1923 they had cleared costs, and in 1924 had made a profit of 5 p.ct., after allowing for 5 p.ct. depreciation. In 1921 the output of gas was 132 million c.ft., and at the end of 1924 it had increased to 159 millions.

Statistics were then given as to the progress of the gas undertaking at Horley between 1913 and 1924. The mileage of mains had increased by 31·6 p.ct.; the number of consumers by 49·7 p.ct.; the sale of gas by 76·6 p.ct.; the prepayment meters in use by 61·3 p.ct.; the ordinary meters by 30·8 p.ct.; stoves by 168·4 p.ct. The gas sold in 1913 was 38,705,300 c.ft., and in 1924, 68,363,100 c.ft. The price of gas in 1913 was 4s. per 1000 c.ft., and the average price in 1924 was equivalent to 5s. 8¼d.

As to the suggestion made by the Electricity Company at Horley that stoking machinery might be installed at the Horley gas-works, witness said that at Horley there were gaseous-fired horizontal retort settings on the regenerative principle, single-ended. It would not be economical to instal machinery for dealing with the number of retorts in use there, nor would it be economical to instal plant to utilize waste heat for the purposes of the works, because steam was generated at present by breeze, for which no market was available. Even if there were no waste heat available at Horley, he would still advocate the generation and supply of electricity there by the Gas Company.

Mr. Tyldesley Jones, cross-examining, said that the people of Horley had been agitating for a supply of electricity for years, but no effort had been made by the Gas Company to give it.

Witness would not agree that the supply had been needed for years.

Counsel suggested that in October, 1922, when the Gas Company had first decided to seek powers to supply electricity, there was a local agitation for a supply, and that it was because of this that the Company had decided to seek powers.

Witness denied this. He maintained that the question had been under consideration by the Gas Company before that time.

In the course of further discussion, Counsel examined the minute book of the Company, to show that there was no minute indicating that the matter had been discussed prior to the holding of a meeting of local residents with a view to forming an electricity supply company. He also referred to the letter from the Secretary of the Gas Companies' Protection Association to the Horley Company, in order to substantiate this. Counsel went on to explain that the first scheme prepared on behalf of the residents was rejected by them, and negotiations were opened with another firm, in London, with regard to preparing another scheme. In February, 1923, a notice had been published by the Gas Company in a local paper to the effect that application had been made by them for power to supply electricity, and he obtained the admission from witness that this was not correct, because application had not been made. Counsel also pointed out that nothing had been done by the Gas Company from February, 1923, until June, 1924, when they had resolved to apply for powers, but at that time another public meeting was held at Horley, at which it was decided to form a company to supply electricity. His suggestion was that the Gas Company would have done nothing but for the action of the local residents. He also said that in September, 1924, a letter was sent to the Secretary of the new Company informing him of the steps taken by the Gas Company, while a similar letter was also sent to the local Press, with a view, he suggested, to preventing the continuance of the new Company. Witness replied that the letter was written to the Secretary of the Company simply for the purpose of making him acquainted with what was going on. The prospectus of the new Company was out by that time, and Counsel suggested that the letter to the local Press was an attempt to stop people from subscribing. Notwithstanding this, over £10,000 had been subscribed by local people. Witness did not know whether those subscribers were local people.

Reference was then made to the development of the gas undertaking, and Counsel referred to a number of areas in which the Company had had powers to supply since 1886, but had not yet given a supply. In these areas there were important clusters of houses which ought to be supplied. Witness said that these areas were situated at some distance from the works, and were rural in character, and that to supply them was not a commercial proposition at the moment.

Replying to further questions, witness said that the Horley Gas Company had approached the London and Brighton Section of the Southern Railway with regard to obtaining a bulk supply of electricity, and the Railway Company had replied that they were prepared to consider it if the Brighton line were electrified. Electrification, however, was too far off.

With regard to the prices charged for gas at Horley from 1913 onwards, Counsel ascertained from witness that the candlepower of the gas supplied in 1913 was 15⅝, which was equivalent to more than 600 B.Th.U. per c.ft. In 1924 the prescribed calorific value was 475 B.Th.U. per c.ft., so that, in order to get the same heating power in 1924 as in 1913, a larger volume of gas had to be used. Thus, said Counsel, if the calorific value of the gas supplied to-day were the same as in 1913, the price per thousand c.ft. would be 7s. 2d. instead of 5s. 8d., and the former figure had to be compared with the pre-war figure of 4s.

With regard to the statement made at the beginning of the proceedings, that 21 gas companies had been granted electricity supply powers, he said that, of those, six had had their powers revoked; two had transferred their electricity powers to other bodies; one had transferred its gas powers to another body; and in one case no supply was given at all. Thus, in twelve cases a supply was being given, and in one of these the Company had no gas powers, so that there were only eleven companies supplying both gas and electricity.

With regard to statements made previously, to the effect that coke breeze was used at the Horley Gas-Works to generate steam, and that there was no market for it if it were not so used, Counsel exhibited the accounts of the Company for the last three half-years, which showed the amount of breeze used at the works and the amount sold, there being none in store at the end of each half-year. This indicated, he said, that there was a local market for breeze.

In re-examination, witness said that he had introduced the question of supplying electricity when he had joined the Company in 1922, and at that time he knew nothing of the attempts made by other people in the district to form a company.

Mr. *Alexander Horn* (member of the Reigate Rural District Council) said he was of opinion that Horley would get a supply of electricity more quickly if it were in the hands of the Gas Company than if it were in the hands of the new Electricity Company. It was also more convenient to the consumers to deal with one Company for the supply of the two commodities than to have two separate companies. It was not correct to say that the Rural District Council were supporting the new Company. The attitude of the Council was to take neither one side nor the other. When a resolution was moved in regard to the Electricity Company's application for powers, the mover had said that he did not ask so much for the consent of the Council, but simply that the Council would raise no objection.

Mr. Tyldesley Jones said he had been told by an official of the Ministry of Health that the Ministry had a formal resolution, sealed by the Rural District Council, giving their consent.

This concluded the case for the promoters.

Mr. Tyldesley Jones, addressing the Committee on behalf of the Electricity Company, said that that Company was formed by local residents for the purpose of supplying electricity in their town, and the fate of the present Bill was of great importance to them. They had subscribed over £10,000, and were prepared to spend more for the purpose of inaugurating a supply, and had had an expensive Parliamentary fight thrust upon them by the action of the Gas Company. Horley should have had a supply long ago; it was bigger than the adjoining district of Crawley, which had had a supply since 1908. The Gas Company had had its hand on this area since 1886, and, with the exception of a very small part, had not supplied gas within it. With regard to the events leading up to the promotion of the Bill, he said the facts were that the Gas Company first decided to ask for electrical powers after the local agitation in 1922, and that the Gas Company had acted in order to defeat this agitation. The first scheme prepared at the instance of the local residents was turned-down in February, 1923. It was in that month that the Gas Company had published a notice in the local paper to the effect that application had been made by them for powers; but this statement was untrue. From that time until June, 1924, the Gas Company did nothing. Then another public meeting was held by the residents. Thus, their first movement, in 1922, synchronized with the local agitation, and the second move, in June, 1924, synchronized with the next public meeting. In the meantime, those local residents concerned with the previous scheme had been negotiating with a London firm with regard to a more suitable scheme; and the negotiations had occupied them up to June, 1924. While the matter was being conducted privately, and the Gas Company knew nothing about it, the latter were quiescent; but when canvassing began, and the matter became known, they wakened up again. It had been said that the Gas Company had delayed, owing to the presentation of a Bill to Parliament to give statutory gas undertakings means of obtaining Orders from the Electricity Commissioners. This Bill, however, was not introduced until May, 1924, and did not explain the delay in 1923. It was thought that one of the best ways to kill the Electricity Company's scheme was to deprive it of money by warning the public not to subscribe, but, notwithstanding the information that the Gas Company proposed to promote a Bill, the public put down the money. If the minimum amount had not been subscribed, he doubted whether the present Bill would have been promoted. An engineer from the Electricity Commissioners had visited the locality and had held an inquiry. A site had been secured adjoining the railway, and objection had been raised with regard to the site; but whoever had engineered that opposition had failed, and the Commissioners had granted an

Order. The initiative in this case was with the Electricity Company. With regard to the question of competition between gas and electricity, he said there ought to be healthy competition; there was no question that the consumers benefited thereby, and it was due to the electrical competition that the gas industry had made the strides it had. It was all the more necessary in small areas such as Horley, where gas companies were apt to be a little slack, unless they had a rival to keep them up to the mark. The expedients that had been used by Mr. Seabrook at St. Marylebone, in order to develop the electricity undertaking there, would not be used by a Company who, if they obtained the electricity load, lost the gas load. There could not be competition between gas and electricity where they were supplied by the one concern.

The Committee then adjourned.

POOLE HARBOUR BILL.

This Bill, which was before a Committee of the House of Lords presided over by the Marquess of Bath, K.G., C.B., on March 23 and 24, was opposed, among other petitioners, by the Bournemouth Gas and Water Company. The main point of the Gas Company's opposition was that they desired power to nominate a representative on the Harbour Board.

Mr. Rowand Harker and Mr. H. F. Bidder appeared for the promoters, and Mr. Arthur Moon for the Gas Company.

Mr. Rowand Harker, opening the Bill, said that its objects were to obtain power to increase the maximum rates of dues and charges by 100 p.ct., to obtain powers as to the remission of certain parts of the boomage rates on vessels of certain classes, as to rebates on boomage rates, and as to qualification for membership on the Board of the Commissioners. The Gas Company did not object to the increase of maximum rates by 100 p.ct., but asked that they should be subject from time to time to revision by the Minister of Transport. They objected to the provision with regard to rebates on boomage rates, and asked for the statutory right to nominate one member on the Board, so that the number of Commissioners would be increased from 18 to 19. The Harbour Commissioners regarded the suggestion as a matter of principle of some importance. The Gas Company apparently claimed that right because at the present time they were the body who paid the largest sums in dues and rates, which statement was perfectly accurate. But it might well be that the time would come when some other body or company would be paying as much or even more than the Gas Company. As a matter of fact, the General Manager of the Company was at present on the Board, and any particular matter which the Gas Company might wish to urge before the Board could be urged by him. But, on principle, the Commissioners asked the Committee not to say that any company, whether statutory or otherwise, should be entitled to nominate a member. It might be suggested that there was a precedent for doing this in the fact that the Southern Railway Company had the right to nominate a member; but the distinction between a railway company and a gas company was, in his submission, obvious. The Southern Railway Company were vitally interested in the welfare of the port from many points of view; and this, no doubt, was the reason which had influenced the Board of Trade in giving them representation.

With regard to the revision of prices, it was suggested by the Minister of Transport that he should have power to revise the maximum charges, whereas at present the Board of Trade had power to revise the actual charges.

Mr. *William Cash* (Chairman of the Bournemouth Gas and Water Company), in evidence, said that the Company were in no sense antagonistic to the Harbour Commissioners, and realized that the interests of the Company and of the Harbour Commissioners were identical. He supported the proposed increase of rates by 100 p.ct., though the Gas Company paid, in fact, about 40 p.ct. of the total income. It was felt that the Commissioners were well advised in making expenditure on the harbour; and if it were necessary to raise the rates, he had no objection. Owing to the large proportion of the rates and dues the Company paid, it was not unreasonable that they should be allowed to nominate a member of the Commission. The Company had a very large interest in the port, and had always worked harmoniously with the Commissioners, but their interests did not always coincide with those of other traders, and, therefore, they would like a representative. It was true that the traders had elected the General Manager of the Company as a Commissioner, but this was only on votes, and the voting lay in comparatively few hands. The Company had only a limited number of votes.

Mr. Arthur Moon, addressing the Committee, said that the position was that the Company, though they supported the application for an increase of rates, considered it ought to be made a condition of allowing the increase that they who chiefly paid that increase should have a representative on the Board. It was the only way to ensure fairness, because otherwise they depended upon the good wishes of the other electors. It was obvious that the time might come when the other persons who had a vote would have different interests from those of the Gas Company. At present the private wharves had 35 votes, and they paid £1400 in dues; the Gas Company had 6 votes, and paid £2500 in dues; other traders had 70 votes, and paid £2100.

There was some discussion as to whether the Committee had the right to alter the constitution of the Harbour Commission. If it were wrong for the Committee to give the Gas Company representation on technical grounds, said Mr. Moon, then the Harbour Board could never be altered unless the harbour authorities wanted to alter it. This would be a farcical result, and he did not think there could be any question that the Committee had absolute power to alter the constitution. From the point of view of voting alone, it seemed that it was not only fair to the Company, but desirable in the interests of the harbour, that the Company should have a permanent representative on the Board. But, in the case of a public utility Company, who were there partly for the benefit of the public, and a Company who had spent money on the public works of the harbour, and a large sum on providing private appliances for loading and unloading their coal, they should be all the more entitled to representation. He was willing, if the Committee considered it fair, that this right should only continue so long as the Company paid a certain proportion of the dues, the proportion to be fixed by the Committee; but he submitted that this limitation was unnecessary. He also said that the Bill would be a better one if the clause giving the Minister of Transport power to revise maximum charges were inserted.

Mr. Rowand Harker contended that if the Committee gave representation to the Gas Company, he did not see how, in principle, it could possibly be resisted in the case of any other undertaker who paid substantial sums. But there was also the question as to whether it was possible to alter the constitution without placing the whole Bill in jeopardy, on technical grounds. Apart from this, the promoters might be met in the other House by petitioners objecting to the alteration.

The Committee decided to allow the Bill to proceed, subject to the inclusion of the revision clause suggested by the Minister of Transport.

THE ELECTRICAL INDUSTRY AND THE SLIDING-SCALE.

The various electricity Bills which embody the agreement with the London County Council for the postponement of the purchase rights of the Council from 1931 to 1971 are now receiving the attention of a Select Committee of the House of Commons presided over by Sir Arthur Shirley Benn. These Bills, it may be recalled, have been suspended since last summer owing to obstructive tactics in the House during the latter part of last session, when the Labour Government was in power; but they have been carried over until this session, having already passed through the House of Lords. At the beginning of this session there were four Bills; but one of them, the County of London Electric Supply Company's Bill, which proposed to take in practically the whole of Essex as a power area, has fallen by the way, having been rejected by the present Government on second reading. There thus remain three measures which have an important bearing upon the scheme for co-ordinating electric supply in the London and greater London area by the Electricity Commissioners. One of them is promoted by what has come to be known as the Ten West-End Companies, and the other is promoted by the remaining four companies which deal with the City and adjacent areas. Both these measures embody an agreement with the London County Council for the postponement of its purchase powers until 1971, at which time the undertakings will be handed over to a Joint Electricity Authority, yet to be constituted, free of charge. The third Bill is by the North Metropolitan Electric Power Company, which also has some bearing—though not such an important one as the other two Bills—on the scheme for supply in the London and greater London area.

With the general details of these schemes we are, of course, not specially concerned; but one point has arisen during the course of their consideration which is of a little interest—namely, the application of the sliding-scale to the electric supply companies in London under the agreement with the London County Council with the acquiescence of the Electricity Commissioners. Here again we are not concerned so much with details as with the principle, and even so only by reason of the fact that the gas industry has been "prayed in aid," an expression lawyers are rather fond of in bringing the matter to the notice of the Committee. The particular form of sliding-scale proposed is one in which the companies are given a minimum dividend and a standard price, so that the slide only operates in one way—namely, in the upward direction. In other words, the company can increase its standard dividend by reductions in price to the consumer, but if at any time it is necessary to increase the price to the consumer, the dividend never falls below a fixed minimum. This is the same principle as has been applied to several gas undertakings since the war, with the object of making it easier for them to raise capital.

During the course of the proceedings on the first of the series of Bills now under consideration, the City of London Corporation have strongly opposed; and their Counsel, Sir Lynden Macassey, K.C., has endeavoured to stress the point that the bargain in this respect is not in the public interest. He made considerable play with the fact that last year, in connection with the Rhymney Gas Bill, evidence was given by Mr. Honey, of the Board of Trade, to the effect that the Board do not now favour the sliding-scale which operates only in the upward direction.

The Chairman of the Committee at one stage interpolated the remark that the position in the gas industry would not influence the opinions of the Committee in connection with these Bills, as the circumstances were so totally different.

Sir Lynden Macassey, however, pressed the point, and contended that Parliament have for all practical purposes abandoned the new form of sliding-scale, and that to ask the Committee to impose this same form of sliding-scale upon the electrical industry—and moreover, the first time that a sliding-scale had been applied to this industry—required very serious consideration, and he would not be doing his duty to his clients if he did not bring the facts before the notice of the Committee.

Later on in the proceedings, Mr. William Cash, who has advised the London County Council in this matter, argued that, in the special circumstances of the London electricity supply problem, he considered that the financial scheme in the agreement with the London County Council, which involves the new form of sliding-scale, is fair and justifiable. Incidentally he mentioned that he would prefer the old sliding-scale, at any rate for large concerns, because, though the ordinary sliding-scale did militate against the issue of new capital by small undertakings, he was not at all sure that the new form was an advantage when it came to big capital issues. He pointed out to the Committee, however, that, in the case of the Rhymney Gas Bill, the Chairman of the Committee which considered it, after hearing Mr. Honey's evidence, gave the decision that he did not rule out the principle of the new sliding-scale, but that the Committee did not think it wise to apply it in the particular circumstances of the Rhymney Company.

LEGAL INTELLIGENCE.

DAMAGES FOR BREACH OF CONTRACT.

On Monday, the 23rd ult., the case of the *Dursley Gas Light and Coke Company, Ltd., v. Low-Temperature Carbonization, Ltd.*, came before Mr. Justice Greer in the King's Bench Division.

Mr. E. A. Digby, who appeared for the plaintiffs, said they had received a letter from the defendants' solicitors, dated March 20, stating that the case would not be defended. The action was brought to recover £7 10s. a day from Jan. 1, or a total of £357 10s. The claim arose in this way: On Jan. 16, 1924, the plaintiffs entered into a contract with the defendants by which the former were to lease to the latter a piece of land on which the defendants were to erect a number of retorts. The gas was to be supplied within three months of the lease being granted. The retorts ought to have been erected some time ago, but nothing had been done up to the present. The plaintiffs had suffered considerable loss through the default, as they had entered into other contracts on the faith of the defendants carrying out theirs.

Dr. *Adams*, the Chairman of the Gas Company, said he had personal knowledge of all the transactions with the defendants. Nothing had been done by the defendants under the contract, and in consequence his Company were suffering severe loss.

His Lordship entered judgment for the plaintiffs for £357 10s., with costs.

AN OXYGEN DISPUTE.

On Wednesday, March 25, the case of the *British Oxygen Company, Ltd., v. Liquid Air, Ltd.*, came before Mr. Justice Romer upon motion for an injunction to restrain defendants until trial or further order from publishing, printing, or circulating a letter of Dec. 17, 1924, addressed by the plaintiffs' Lancashire district agent to Tanks & Drums, Ltd., of Bradford, in which he set out the terms on which the plaintiffs were willing to supply oxygen to that Company, and from allowing the letter to be photographed, or copies and extracts made for the purpose of informing the public of its contents.

Mr. Upjohn, K.C., said the plaintiff Company was formed in 1886 to make and supply oxygen, and to make oxygen plant. Defendant Company was formed in 1913; the business being the manufacture of oxygen gas plant. Plaintiffs were in a large way of business, and had installations throughout the country, from which oxygen was supplied in cylinders. Among other customers were Tanks & Drums, Ltd. The defendant Company were minded to become their rivals in the sale of gas plant, so that purchasers could make their own oxygen. Among other firms, they approached Tanks & Drums, Ltd., who were old, and large, customers of the plaintiff Company; and the latter, not wishing to lose their business, instructed their Lancashire district manager to write offering a low quotation for oxygen, on condition that they took a certain quantity, and did not set up any plant to supply. The defendant Company's Manager heard of this letter, and having obtained a copy from the Manager of Tanks & Drums, Ltd., had it photographed. Copies were then forwarded to brokers and jobbers on the Stock Exchange, with a request that it should be shown to others who were interested in dealings in the shares of the plaintiff Company. The result was a fall in the price of the shares. The price quoted to Tanks & Drums, Ltd., was a special one, at which they could not offer to supply small customers; but the quotation had been used to convey the impression that the effect of the defendants' competition was such that the plaintiff Company had to reduce their price to one at which they could not possibly make a profit.

Sir H. Slesser, K.C., for defendants, denied that photographs of the letter had been shown on the Stock Exchange.

Mr. Upjohn, in answer to his Lordship, said he rested his case on copyright, and, next, that there had been a breach of confidence.

Sir H. Slesser submitted that the question at issue could not be properly tried on motion, but should be dealt with at the trial. For a long time the plaintiffs had tried to interfere with the defendants' business, so as to prevent their raising further capital and getting a quotation on the Stock Exchange. He contended that defendants were entitled to use the letter, to protect their own interests. The motion was, in his view, an abuse of the process of the copyright law.

After hearing the affidavits filed on both sides, the hearing was adjourned till the following day.

On Thursday,

Mr. Upjohn contended that the copyright of the letter being the plaintiffs', the defendants were clearly in the wrong in multiplying copies by means of photography.

Sir H. Slesser contended that the letter in question was not a literary work in any sense, but merely a commercial document in which there was no copyright within the meaning of the Act of 1911. But, assuming the letter was a literary work within the meaning of section 1, the defendants had only used it—as they were entitled to do—for the purpose of criticism, and to show how the plaintiffs were trying to injure the defendants' business. All they had done was to protect their own interests. The Court having a discretion in this class of case, he asked his Lordship to hold that, having regard to all the circumstances, the letter was not one which ought to have the protection of the law of copyright.

His Lordship reserved judgment.

Auckland (N.Z.) Gas Company, Ltd.—The profits for the year's working amount to £70,036, making, with the balance of £34,519, £113,555. The Directors recommend a dividend for the past half-year at the rate of 8 p.c. per annum on the £1 fully-paid shares, and proportionate amount on the contributing shares, 4s. paid. This will leave £37,457 to be carried forward.

MISCELLANEOUS NEWS.

JUBILEE OF THE MUNICIPAL GAS-WORKS AT THE HAGUE.

The following interesting particulars are extracted from an attractive brochure for which we are indebted to the courtesy of the Manager of the Hague Gas-Works, Mr. J. E. H. Bakhuis:

In 1844, when the competition of "portable" gas, supplied in iron casks, was still a thing to be feared, a concession for the supply of gas at the Hague through mains was granted to Mr. Neville Davison Goldsmid, who erected a plant in the Lijnbaan. The price originally charged was 24½ c. per cub.m., equivalent to about 11s. 6d. per 1000 c.ft. In 1875, this works was purchased by the Municipality for £43,000; but as the plant proved to be inadequate for the growing consumption, it was decided to build a new station in the Loosduinschen weg. The opening of this works in 1876 was followed, in 1879, by the shutting-down of the Lijnbaan Works, where the cost of production was considerably higher than at the more modern station. By 1886 the price of gas had been reduced to 7 c. per cub.m., equivalent to 3s. 3d. per 1000 c.ft.

Mr. J. E. H. Bakhuis, the present Chief Engineer, succeeded Mr. Kros as Manager in 1896. In 1905 the works in the Loosduinschen weg began to approach its maximum output of 150,000 cub.m. (approximately 5,300,000 c.ft.) per diem; and the Municipal Authorities—true to their policy of reducing the cost of production—therefore decided to construct yet another new works on the Trekvliet canal, which gives 500-ton barges direct access. The present daily output of this works (opened in 1907) averages 150,000 cub.m., the length of mains being 428 km., or about 265 miles, and the number of consumers 85,000. It is interesting to note that the leakage, which in 1875 amounted to 26·7 p.ct., is now only 2·67 p.ct., or exactly one-tenth of what it was fifty years ago.

The old works in the Loosduinschen weg was closed in 1924.

ALLIANCE AND DUBLIN CONSUMERS' GAS COMPANY.

Half-Yearly Meeting.

The Half-Yearly Meeting of the Company was held on March 25—Mr. F. J. Dickens presiding.

The Chairman, in moving the adoption of the report and accounts, said that two of the most satisfactory features in the accounts were: A further increase of 5¼ p.ct. in output, and the marked diminution in the quantity of unaccounted-for gas. The sales of gas in Dublin to-day were more than 60 p.ct. greater than they were immediately before the introduction of electricity. In the circumstances, it is strange to find there were still people who thought the days of gas were numbered. During the year they had secured 2212 new consumers, and 2778 new cooking and 860 further heating stoves had been sent out. The expenditure on manufacture of gas was approximately the same as the corresponding period—the actual figures being £150,157 in 1923, and £152,358 in 1924. As to the income obtained from residual products, the results were decidedly better than in 1923, as there had been an increase of no less than £15,436. The future outlook for the residual market, however, was not so good.

The total cost of distribution of gas was larger by nearly £4000. Most of the increase was due to the special examination of consumers' service pipes, which, as he had explained on a previous occasion, was being carried on with the object of giving, where possible, a more efficient supply, and, at the same time, tracing any leakage which might exist, so as to cut down to a minimum the loss under this head. In the repairs of meters account, there was an increase of something over £1700, by reason of the fact that a substantially larger number were repaired.

To sum up, expenditure for the half-year was down to the extent of £1347, while income was up by £1586, and thus they were enabled to carry into net revenue a profit larger by £2933. The balance of net revenue available, £60,068, would permit of a somewhat larger dividend being paid than that recommended, but the Directors felt convinced that 6¼ p.ct. should not be exceeded. As the reserve fund still required to be strengthened, and this could only be done out of divisible profits, an appropriation was recommended of £8275, which would bring it up to the round figure of £75,000, and the balance of £3296 would remain to be carried forward to the next account. The balance-sheet again disclosed a satisfactory state of affairs. The funds showed an increase of over £27,000, while liabilities to tradesmen and others had only slightly advanced. Stocks were heavier, and debtors had fallen by approximately the same amount. The value of investments was larger by £12,000.

Mr. Augustine Bird seconded the motion, which was passed.

The Chairman moved, and Mr. W. H. Davies seconded, the declaration of a dividend at 6¼ p.ct., less tax, on the consolidated ordinary stock of the Company. This was agreed to.

The Yorktown and Blackwater Gas Company.—The Company are holding two exhibitions this week. A complete and comprehensive display of "Richmond" cooking, heating, and water heating apparatus (which includes a series of their popular "Bungalow" cookers) has been tastefully arranged in the Woodcliffe Hall, Wargrave, and also (for the latter half of the week) at the Assembly Rooms, Twyford. Both of these new districts promise rapid development; and the Gas Company are to be congratulated on their initiative in running the necessary mains and in organizing these exhibitions to popularize the use of gas. An interesting series of cookery lectures and demonstrations is attracting a gratifying attendance; and special baking competitions for adults and children have aroused considerable interest in both districts.

RADIATION LIMITED.

At the Annual Meeting of the Company, held at the Queen's Hotel, Birmingham, on March 24, the Chairman, Mr. H James Yates, in moving the adoption of the report and accounts, said:

Radiation Policy.

It may perhaps be in the memory of some now present that when I first addressed you as Chairman of Radiation I outlined the policy which we proposed to follow. As I then stated, the object of bringing together the principal gas stove manufacturers of this country was to stop the waste occasioned by their vying with each other in useless expenditure; to "pool" the knowledge and capacity of the various companies; to concentrate more than ever on research work; to embody the results of that work in the types of apparatus we made; and, as far as possible, to standardize these types, so that all the component parts should be interchangeable—a matter which means so much to our largest customers, the gas undertakings, who maintain these stoves and stock the parts necessary for this purpose. The firms comprised in Radiation had always been in the van of progress; but it was felt that, by the uniting of their efforts, a much higher standard could be set—that we could produce better goods, increase the output, and give greater value for money. This policy we have ever since steadfastly pursued. High as the standard is which we set for our goods, and which we have attained, we are aiming to reach one still higher. The first cost of an apparatus to the purchaser is not necessarily the only consideration; but the higher the quality of that apparatus, the greater the satisfaction it gives to the user, and in the long run the less expense is required for keeping it in condition. It was our intention—and we have succeeded in translating that intention into accomplished fact—to make the "hall-mark" of Radiation upon any gas apparatus a guarantee that it is of the best quality attainable, and that it will give the longest service with the highest efficiency. We have also created the position that people who purchase Radiation apparatus appreciate that our services and advice are always available to anyone who requires them. To produce goods on such lines, and create such a position, naturally adds to cost; but though, consequently, our prices may not always be the lowest in cash amount, they actually are the lowest when their durability and also their economy in gas consumption are taken into account.

A Successful Year.

Our year's trading has been a successful one; but, like all other manufacturing concerns, we have had many difficulties to overcome. Our business has greatly increased, and as a result we have had to make extensions to our various works.

Our costs of production in some sections have risen; while in the case of others we have derived some benefit from our introduction of still further improvements which have reduced cost. Our object is continually to expand our business, and, as our costs come down, to give a full share of the benefit to our customers. The larger a business is, the less it "feels the draught" when times are bad; and for this reason it is far better to have a big turnover with a smaller margin of profit than a smaller turnover with a big margin of profit.

The Burden of Taxation

I shall not attempt to go into details regarding the position of British manufacturers in respect of export business. You are aware of the conditions that exist in other countries as compared with ours, and the exceptionally heavy taxation we have to bear. The handicaps against British manufacturers are both numerous and heavy. Last spring the then Chancellor of the Exchequer gave official figures as to the taxation per head of population—man, woman, and child—in this country and abroad. The taxation in this country was given as £15 18s. per head; in the United States, £6 14s. per head; and in Italy, £3 6s. 11d. per head. I learn that it has lately been officially stated in the House of Commons that the figure in France is about 441.5 frs., which works out at £5 11s. 5d. per head. The figure in Germany cannot be given with close accuracy, but a year ago I believe it was somewhere about £4. It was lately pointed out in the Press that the amount we are paying for income-tax includes 2s. 7½d. in the pound for war debts, of which amount 1s. 11d. in the pound is on account of the debts incurred by us in order to lend to our allies. While we are bearing this burden, our allies are relieved of their equivalent debt to us, and consequently relieved also of the taxation which they would have otherwise had to pay in order to liquidate these debts; so that this imposes on British manufacturers a crippling double handicap. If this heavy handicap of ours in the matter of taxation could be borne in mind by all classes of people in this country, they would realize more than ever the necessity for us to cut our own domestic expenditure—and consequently our taxation—down to the lowest limit, and to ensure the greatest output of all those things that we make for export, so as to bring down the cost.

Fuel Competition.

I believe that an essential condition of this country's future prosperity lies in the obtaining of cheaper fuel. It is necessary that we should have a larger output of coal, with a reduced cost, as fuel enters directly and indirectly into the cost of everything that is produced, including our food. Owing to the high cost of solid fuel, oil fuel is rapidly coming into use; and I believe we are going to see a great diminution in the use of solid fuel in the future. One has only to be on board a ship to realize the advantages of the use of oil fuel, even though it should cost the same as solid fuel. When a ship enters a port for fuelling purposes, in the case of oil, pipes are employed to convey it on board, and the filling of the tanks is conducted with speed and cleanliness, the least possible labour, and with no discomfort to the passengers; whereas with solid fuel the time and labour involved, and the dust and grime that fall to the lot of the vessel and the passengers, are things I need not enlarge upon. One cannot but reflect what a serious thing it would be for this country if these conditions were to lead to a general discontinuance of the use of solid fuel for shipping purposes; and the only way of avoiding this would appear to be for solid fuel to be so cheap as to prevent the general adoption of oil fuel by effective competition in price.

Our Imitators.

The progress of Radiation has been so striking as to involve us in one of the penalties of success—namely, that sincere form of flattery which lies in imitation; and our various apparatus have received a good deal of this attention for some time past—particularly so at present. Our own endeavour is to keep inventing and producing the best apparatus that experience and scientific research can evolve. We fully recognize that it is detrimental to our business that unsatisfactory apparatus should be offered by small makers. As an instance, take a gas-fire, which for long was looked upon with such prejudice, although fortunately this prejudice is now a thing almost wholly outgrown. If a gas-fire made by one of those makers finds a market on account of its price, and gives dissatisfaction to the user, the matter does not end there—the user condemns gas-fires as a whole, probably not knowing that there are perfectly satisfactory types to be had; and his bad opinion of them spreads.

The desirable thing in all interests is that all makers should produce gas-fires which give satisfaction. This would help the whole industry, as every gas-fire in use and giving satisfaction—no matter by whom it is made—will help to extend the general use of gas-fires. We want to see a healthy rivalry, not only in price, but in original inventions and improvements; but what we shall always denounce, and do everything in our power to prevent, is the producing and selling of imitations of those inventions which we have brought out at so great an expenditure of research, experience, and money. In recent times we have had to take legal measures against several imitators, not only in this country, but abroad; and in each instance the matter has been settled in our favour. There are still other important similar matters pending; and if the copyists are wise, they will realize that it is better for them to develop their own ideas rather than slavishly copy ours. Our motto is "Live and let live;" but it must be read to mean "Live at your own expense, and let us live at ours," although even then our work cannot but be helpful to others besides ourselves.

Research Work Development.

We are greatly extending and developing the research work of the Company. All along we have had in each of our works chemical and physical laboratories for research work, and in these we have also carried on regularly searching tests of all materials used in the construction of our apparatus, as well as the testing of all apparatus before it leaves the works. We are now constructing central research laboratories in London, on premises belonging to us and adjoining Radiation House. When these new central research laboratories are completed—which I hope will be in a month or two's time—they will constitute one of the finest and best-equipped research laboratories in the country, staffed by chemists of high scientific training, and of unrivalled special experience in all those branches of research with which our manufactures are concerned

While it is our intention primarily to devote all our energies to our own research work, we are cordial believers in co-operation and mutual assistance within the gas industry.

The "New World" and "New World Junior" Cookers.

In addressing you last year, I referred at some length to our new type of cookers, the "New World" and the "New World Junior," with the automatic heat-regulator called the "Regulo," which enables any person to use the oven with unerring certainty of success. This new type of cooker has completely transformed gas cooking. The cookers are not merely new patterns of apparatus, they are conceived upon new principles, only arrived at after years of research work and the expenditure of many thousands of pounds. The spontaneous encomiums they are constantly evoking is a great satisfaction to those of us who have been associated with the evolving of this type and the placing of it before the public. The new type has come to stay, and I regard it as among the most important assets of the Company. The reception of the "New World Junior" cooker affords every prospect of its realizing to the full our aim, that it should be—to repeat the "slogan" which I quoted to you last year—"A cooker for the million at a price for the million."

In passing, I must refer once more to the boiling burner in the hot-plate of these cookers which embodies a new principle, and which is called the "Rado." This type of burner has become the standard not only in this country but in our Colonies, and also, notwithstanding the difficulties of exchange and other obstacles, large numbers have been sold on the Continent and in various parts of the world. Imitators have done us the honour of copying this burner as near as they can; but they have still much to learn in order to produce a burner like the "Rado." The "Rado," to all intents and purposes, replaces the drilled-ring type of burner, as by its means the actual consumption of gas has been considerably reduced, and the combustion always remains complete; the burner cannot become clogged-up in use; and there is no risk of those unpleasant odours so often experienced in connection with the older types of gas cookers.

We spend a large amount in advertising our goods in the Daily Press and periodicals; but the benefit of much of our energy and outlay in this direction would be lost were it not for the enterprise of the gas undertakings, who, through their individual and organized efforts, make it so easy for householders to obtain and have fixed up any type of gas apparatus they may wish, with the least trouble and expense to themselves. Not only so, but the gas undertakings afterwards maintain a careful supervision of these apparatus in use.

"Thermo XX" Gas-Grates.

The sales of the Radiation "Thermo XX" injector-ventilator gas-grates last year have far exceeded all previous attainment. The injector-ventilator invention, as I have explained on a previous occasion, removes the last inequality of the gas fire as compared with the coal fire by giving ample ventilation of the room. It has no greater friend than the medical profession. At one time none con-

lemned the use of the former types of gas fires and grates more than the doctors; but since our creation of the modern hygienic, ventilating, and silent gas-grate, doctors are among the greatest gas-fire advocates.

The Smoke Problem.

The dense fogs experienced in this country during the present winter—and particularly in London—have directed renewed attention to what may be literally called "a burning question," and brought afresh before the public mind the important truth that it is not the factory smoke-stacks so much as the many thousands of domestic coal-fire chimneys which have so great a share of responsibility for these fogs. It is estimated that in London alone it costs a million pounds for each day that fog prevails. What it costs beyond this in sickness and impaired vitality due to the loss of the health-giving effects of sunlight is something far beyond calculation. It is coming more and more to be realized that sunlight is not merely a pleasant thing for the senses and a good thing for the life of plants, but that it is also a vital thing for the health of human beings. I hope the time is not far distant when legislation will be brought about to make it an offence to use any apparatus which helps to produce the "smoke-counterpane," as Carlyle would call it, which overspreads our country so much and so thickly. To burn solid fuel in its crude form in coal-grates is to do a grave injury to the community; and it is important to remember that when coal is burned in its crude form in an ordinary coal-grate, the direct waste of fuel is estimated at 5 p.ct., with a total loss of all the available bye-products, such as chemicals, disinfectants, oils, dyes, and many other things one could mention, which are so indispensable to us.

In telling you of the various matters connected with the Company's affairs, I have naturally dealt more particularly with the larger part of our business—namely, that which is concerned with the manufacture of gas apparatus and gas meters. Many of you, however, are aware that the business of our Company stands on a broad basis, and includes among its many activities a very extensive foundry business and a large enamelling business, and the goods made in our foundry business are extensively used in connection with all building schemes.

Education in Industry.

There is a subject to which I have referred on a number of occasions, and which I do not propose to enlarge upon now, but merely to mention in passing—namely, the educational scheme for the teaching of the economics of industry to workpeople, a scheme which I took a leading part in initiating some years ago through the National Alliance of Employers and Employed. Last year I gave some details of the growth of this educational scheme, and it has extended enormously during the past year. It has so established its position, and proved the value of its work, that it has now received full recognition from the Board of Education. Those of you who are associated with any kind of works, and who may not have already given opportunities for your workpeople and staff to avail themselves of this scheme of education, I strongly urge to write to your local office of the N.A.E.E., and obtain the necessary information. I can assure you that if you adopt this scheme, after you have had it in operation for some little time you will find your workpeople and staff more intelligently appreciating the difficulties met with in carrying on your business in these days; there will be a better understanding between them and yourselves; more co-operation; and a disposition to give a better output. The outlook of your employees will be improved, and so will your own, and there will be a happier and more contented feeling all round.

An Investors' Security.

When I first had the pleasure of addressing you as Chairman of Radiation, I said: "We want the Radiation shares to be recognized as an investors' security, and not as a speculators'; and it is the hope and aim of the Directors that Radiation should become known—by the steadiness of the Company's policy, and the absence of sensational occurrences in connection with the shares—as what I might call a gilt-edged industrial investment." I am referring to those remarks now in view of recent statements that have appeared in the Press and elsewhere. It is the policy of your Board to strengthen the internal affairs of the Company as far as it is humanly possible, so as to ensure against fluctuation in dividend and to be prepared for the "rainy days" which at some time or other come to all manufacturing concerns.

As I have mentioned earlier, we are determined to extend our business by every proper means at our disposal; and as we extend the business, so we hope to put ourselves in a position to produce at a lower cost. The time may come when it may be possible for us to increase our dividend; but in the opinion of your Directors no increased dividend should be paid until the financial resources of the Company have been put in a position to withstand any stress that might come upon them, and we do not consider that time has yet arrived. It does not follow because a concern has made a profit that they ought to distribute it by way of dividend. We have greatly extended our various works, including purchases of additional land; we have to carry much increased stocks; and, consequently, our debtors are also greatly increased. This is a heavy call upon the resources of any business. Also each year opens with its potential difficulties in prospect, and this year is no exception. In industrial concerns there is always an element of the unknown which has to be allowed for, and that is why we are anxious that the resources of the Company should be so strengthened as to be in an absolutely stable position, safe against all contingencies which could be reasonably anticipated.

No doubt you and I, or most of us, have at one time or another bought shares of different concerns on mere hearsay as to the possibility of certain things happening in these particular concerns; and we have done this with varying results. If anyone has been buying Radiation shares in the hope of an early increased dividend, I am sure they will not desire to blame anyone else because they have not obtained what they looked for.

I will conclude, gentlemen, by moving:

"That the report and balance-sheet for the year ended Dec. 31, 1924, as presented by the Directors, be approved and adopted."

The report and accounts were adopted.

GAS REGULATION ACT APPLICATIONS.

There have appeared in the "London Gazette" the following notices regarding applications to the Board of Trade under the Gas Regulation Act.

SPECIAL ORDERS

Aldershot Gas, Water, and District Lighting Company.

The Company give notice of their intention to apply to the Board of Trade for an Order under section 10 to enable them to raise further money, and to make provision with respect to the voting at meetings.

Colchester Gas Company.

The Company are seeking a Special Order to authorize them to raise additional capital, to make further regulations in connection with the supply of gas, and for other purposes.

DECLARATIONS OF CALORIFIC POWER.

Houghton-le-Spring District Gas Company.—480 B.Th.U. (July 1.)
Swindon United Gas Company.—425 B.Th.U. (July 1.)

NUNEATON GAS PRICES.

280 B.Th.U. Gas.

The Nuneaton Gas Company, towards the end of last year, gave notice to the consumers that the calorific value of the gas which they intended to supply, as from March 11, would be 280 B.Th.U. per c.ft. Also that from the date of the current reading of the meters and the March collection of prepayment meters, the prices of gas (gas only, and not including hire) would be as follows: Prepayment consumers, gas only, 1s. 6·2d. per therm; 4s. 2·96 per 1000 c.ft. Prepayment consumers with hire-purchase fittings, 1s. 6·2d. per therm; 4s. 2·96d. per 1000 c.ft. Ordinary consumers, 1s. 6·2d. per therm; 4s. 2·96d. per 1000 c.ft. Cooker consumers (conditional), 1s. 3d. per therm; 3s. 6d. per 1000 c.ft. Gas fire consumers (conditional), 1s. per therm; 2s. 9·6d. per 1000 c.ft. Engine consumers (conditional), 9d. per therm; 2s. 1·2d. per 1000 c.ft.

The notice explains that the slot meters are set to cover the cost of gas, meter rent, and fittings on hire. Regarding the above prices by volume, it will be noted that 2·8 therms equal 1000 c.ft.

TRADE NOTES.

British Gas Purifying Materials.

The British Gas Purifying Materials Company, Ltd., whose head office is at No. 99, London Road, Leicester, and late of No. 13, Arcadian Gardens, Wood Green, N., have reopened a London office at No. 34/35, Norfolk Street, Strand, W.C. 2, which will be under the management of Mr. H. R. Hill, whose family have been closely connected with the gas industry since its inception.

Labour-Saving Machinery.

A reference book of information relating to the design and application of conveying, elevating, screening, and transmission machinery has been published by the Hebburn Conveyor Company, Ltd., of Wakefield. The guiding idea of this new publication has been to present illustrations and information of differing and typical installations, to assist probable clients in the selection of machinery.

CONTRACTS OPEN.

Resetting Retort Bed.

Tenders are invited by the Haworth Urban District Council for the resetting of retorts. [See advert. on p. 74.]

Exhausting Plant.

The Edinburgh Corporation are prepared to receive tenders for the supply and erection, at the Granton Gas-Works, of a steam-driven four-blade exhausting plant. [See advert. on p. 74.]

Colonial Gas Association Capital Issue.—The issue of preference shares in the Colonial Gas Association, Ltd., the abridged prospectus of which was advertised in the "Journal" for March 18, has been largely over-subscribed. Letters of partial allotment are being sent out this week.

Barnard Castle Gas Company.—The question of undertaking the supply of electricity to the town is under the consideration of the Company. At the annual meeting on March 26 the report of the Directors showed that the sale of gas had increased during the year by nearly a million c.ft. The gross profit was £1210, while the net balance on profit and loss account was £676, which was available for dividend. An interim dividend was paid for the first half of the year, and it was decided to pay a like figure for the second half—4 p.ct. on the original consolidated stock, and £2 17s. on new ordinary stock, free of income-tax, absorbing £260 and leaving £416 to carry forward. The Directors reported that they had taken expert advice on the question of the electricity undertaking. The capital cost was estimated at £14,685, and the estimated revenue for the second year was £3460, leaving an estimated margin for profit of £990. The Directors thought, however, that there would be difficulty at the present time in raising the required capital. It was decided to ascertain by a canvass of the town the number of likely electricity customers.

NORTH-EAST COAST COAL TRADE.

From our Own Correspondent.

The same general idle conditions continue in the market, and prospects are in no way improved. Some days seem less depressing than others, when a few inquiries from abroad are circulating, but the end of them is generally "gone to Germany." Home demand is not improving, and stocks everywhere on the Continent are large. Consumers continue to buy only for their immediate requirements, and in very few cases can collieries see more than a short distance ahead.

A feature has been a further weakening of Northumberland screened steams, which now range between 16s. 9d. and 17s. 6d. according to quality. Durham coals have not changed appreciably in value, though the demand remains as poor as ever. Wear Special gas makes quote 20s. 6d., but they can probably be had at considerably less than this for prompt definite business. Best qualities (Holmside, Boldon class) are nominally 20s., but obtainable, at any rate in the case of some of them, down to 19s. Other qualities are still 17s. to 17s. 6d. Best unscreened bunkers are about 18s. 3d., and coking unscreened still in poor demand at 17s. 3d. to 17s. 6d.

COAL TRADE IN THE MIDLANDS.

From our Local Correspondent.

The increasing seriousness of the position as the volume of demand contracts and the ratio of overhead charges grows, deepens the anxiety which is felt in every branch of the trade. It is stated that 90 p.ct. of the gas undertakings are in arrear of their contracts. Stocks are so heavy that it is not easy to see how the leeway is to be made up. There is speculation as to what effect this will have upon new contracts when the time comes for negotiation. The market for both household and industrial fuel has become extremely sluggish. Stocks in intermediate hands suffice to satisfy a considerable part of the current demand. The position at the collieries can be inferred from the promptitude with which orders are dispatched. Depreciation of values is accentuated in all descriptions of coal save the best household grades. Two or three weeks are still required for delivery of the latter. The consumption of works fuel tends to decline. In the Staffordshire iron trade, a large amount of plant is idle, and works that are not stopped are running in many cases intermittently.

The stagnation in the pig iron trade reacts on the coke market. Prices are precarious, and the view of ironmasters is that trade recovery is only possible with cheaper fuel. How this is to be reconciled with the present cost of coal-getting, and the unsatisfactory yield of residuals, is the problem to be solved.

YORKSHIRE AND LANCASHIRE COAL TRADE.

From our Local Correspondent.

There is no material alteration in the situation of the coal trade in Yorkshire and Lancashire. Gas coal is moving slowly, with indications of decreased prices for renewals of contracts.

House coal continues steady, with prompt supplies available at the majority of the producing points.

Although a better tone prevails among certain of the industrial coal consuming centres, there is no apparent increase of business, notwithstanding that low prices are being quoted for prompt deliveries of the lower-grade fuels. What difference the irregular working of collieries in the near future will make is problematical; but the outlook suggests that some kinds of slack may become scarcer.

The slump in export still continues, with no prospects of improvement, and prices for all qualities are in consequence exceptionally low.

Humber bunker and export prices (f.o.b. usual shipping ports) at the week-end were: South Yorkshire: Hards, Association, 19s. 6d.; screened gas coals, 19s. 6d. to 20s. 6d.; washed trebles, 20s. 6d. to 21s.; washed doubles, 17s. 6d. to 18s.; washed singles, 17s. 3d. to 17s. 9d.; washed smalls, 13s. to 13s. 6d.; unwashed doubles, 15s. 9d. to 16s. 3d.; rough slack, 11s. to 11s. 6d.; smithy peas, 20s. 6d. to 22s.; West Yorkshire Hartleys, 17s. to 19s.; screened gas coal, 19s. to 20s; washed trebles, 18s. 6d. to 19s.; washed doubles, 16s. to 16s. 6d.; washed singles, 16s.; washed smalls, 13s.; unwashed doubles, 13s. 6d. to 14s. 6d.; rough slack, 11s. to 11s. 6d.; coking smalls, 10s. 6d. to 11s. Derbyshire and Nottinghamshire: Top hards, 19s. 3d. to 20s.; washed trebles, 18s.; washed doubles, 18s.; washed singles, 17s. 6d.; washed smalls, 12s. 6d. to 13s.; unwashed doubles, 15s. to 16s.; rough slack, 10s. 6d. to 11s. 6d. Yorkshire, Derby, and Notts: Screened steam coal, 16s. 6d. to 18s.; gas coke, 21s. to 23s.; furnace coke, 17s. 6d. to 18s. 6d.

Queenstown Gas Company.—Presiding at the annual meeting of this Company, Mr. John Roonon (Chairman) pointed out that the bank overdraft had been increased, owing chiefly to a debenture of £600 having been redeemed during the year, and, for the rest, to recent changes in the gas industry—the introduction of cookers and heaters, and the fitting-up of appliances at the Company's expense, which naturally led to more capital being required. To meet this demand they had to borrow, as the troubled conditions that had prevailed in Ireland were not, of course, favourable to raising capital otherwise. When conditions were more settled they would, he hoped, be able to raise capital for further development. He conveyed to Mr. W. E. Young (Resident Manager) and the staff the thanks of the Directors for their loyalty and support. The report was adopted and the statutory dividend declared. At an extraordinary meeting, held subsequently, the Directors were authorized to borrow, if they thought fit, to the extent of the Company's unexercised powers.

STOCK MARKET REPORT.

The announcement of the new Government Conversion Loan was the event of the past week. The terms of the issue, which is for £30,000,000 3½ p.ct. stock with a minimum price of 76¾, were almost identical, after allowing for the periods of the first interest, with those of the last issue. Fears of dearer money are still prevalent in the City, and the uncertainty continues to dominate the stock and share markets.

The 5 p.ct. War Loan remains the cheapest stock in the gilt-edged section, and taking the four months' accrued interest into account can be purchased at below par. Foreign bonds were neglected. Home Rails improved slightly, though the business done was insignificant.

The Industrial Market generally was also depressed. Courtaulds fell away by about 2s. 6d., due possibly to "bear sales." The Dunlop report made a good impression, notwithstanding the fact that there is again no dividend. There has been a good deal of criticism of the Harland and Wolff report, and subscribers to the issue last year of preference shares, which have dropped from £1 to 14s., have good reason to ask for more information with regard to the Company's working.

In the Gas Market the depression still continues. It will be seen from the Table that the Brentford stock dropped a further 2 points to 103-108, which, when one considers that on the news of the amalgamation with the Gas Light Company becoming known transactions took place at 118, is significant, notwithstanding that the Bill has passed the third reading in the Commons. The variation in the quotation of the Gas Light ordinary (now 88½-90½) and the Commercial 4 p.ct. (91-94) is surprising, in view of the fact that at the present prices of gas, 8·6d. and 9·4d. per therm respectively, the authorized dividends for the current half-year are the same—viz., £5 6s. 8d. p.ct. per annum. An important change is the fall of 4 points in the South Suburban ordinary to 100-105. There will shortly be an inquiry into this Company's standard price. The announcement of the Tottenham Company's revised standard is doubtless the cause of the 2¼ points fall in the "B" stock; the "A" stock so far has not been affected.

The following transactions were recorded during the week:

On Monday, Bristol 5 p.ct. maximum 93⅞, Commercial 4 p.ct. 91½, 3½ p.ct. 91½, 3 p.ct. debenture 58, Gas Light and Coke 89⅝, 90⅛, 90⅜, 3½ p.ct. maximum 63½, 4 p.ct. preference 79, 3 p.ct. debenture 60½, Imperial Continental 178⅛, 180, Primitiva 7s. 9d., 8s. 1⅜d., 8s. 3d., 4 p.ct. 1st debentures 79⅝, 80, South African 7⅛, South Metropolitan 95½, 96¼, 96½, 3 p.ct. debenture 61⅛, Swansea 7 p.ct. preference 102⅜, Tottenham "B" 101, Wandsworth "B" 114. Supplementary prices, Ascot new 6 p.ct. preference 101⅛, 10⅛, Kingston-upon-Thames 105½, 105⅛, Wandsworth 3½ p.ct. new 97.

On Tuesday, Alliance and Dublin 70⅝, Bristol 5 p.ct. maximum 93, 93⅛, Continental Union 7 p.ct. preference 89, European 6¾, Gas Light and Coke 89½, 89⅝, 89⅞, 90, 4 p.ct. preference 79⅜, Hastings and St. Leonards 5 p.ct. 94¼, 94⅜, Hornsey 137⅞, 138, Imperial Continental 181, Primitiva 7s. 9⅝d., 8s. 1⅜d., 4 p.ct. 1st debentures 79⅞, 80, South Metropolitan 95¼, 95⅜, 95⅝, 95⅞, 96, Tottenham "B" 100. Supplementary prices, Bath 5 p.ct. debenture 97½, Southend-on-Sea 5 p.ct. new "B" 88½, 89.

On Wednesday, Alliance and Dublin 4 p.ct. debenture 67½, Bombay 5 1/16, Brentford "A" 105, European 6¼, 6⅝, 6 11/16, 6¾, 6 13/16, Gas Light and Coke 89, 89⅜, 4 p.ct. preference 79¼, 3 p.ct. debenture 61, Hastings and St. Leonards 5 p.ct. 94⅜ *ex* div., Montevideo 64½, 65, Primitiva 8s. 3d., 4 p.ct. (River Plate) debenture 65½, 66¼, Sheffield "B" 102⅜ *ex* div., South Metropolitan 95, 3 p.ct. debenture 60⅜, South Suburban 104.

On Thursday, Commercial 4 p.ct. 91, Continental Union 37, 37⅛, European 6⅝, 7, 7 1/16, Gas Light and Coke 89, 89⅛, 89⅜, 89⅝, 89¾, 3½ p.ct. maximum 63¼, 63½, 4 p.ct. preference 78½, 80, Imperial Continental 180, Liverpool 7 p.ct. preference 103½ *ex* div., Montevideo 64⅜, 65, Primitiva 8s. 3d., 8s. 4½d., 4 p.ct. 1st debentures 79⅜, 80, San Paulo 6 p.ct. preference 7⅜, 7 13/16, *ex* div., South Metropolitan 94, 94⅜, 95, 95½. Supplementary prices, Gas Light and Coke 10 p.ct. bonds 198.

On Friday, Bombay 5½, Cape Town 7¼, 4½ p.ct. preference 6¼, 4⅜ p.ct. cons. 1st mt. debenture 73, European 7⅛, Gas Light and Coke 88⅜, 89½, Imperial Continental 182, Primitiva 8s. 1⅜d., 8s. 9d., South Metropolitan 94⅜, 94⅝, South Suburban 5 p.ct. 100, Southampton 84, 84½, Tottenham "A" 119, "B" 100, Wandsworth (Wimbledon) 111, 112. Supplementary prices, Cheltenham 5 p.ct. max. 78½.

Money was scarce in Lombard Street last week, and a small amount had to be borrowed from the Bank of England at 5½ p.ct. The Treasury Bill rate rose again; the average rate at which bills were issued being £5 7s. 1·59d. p.ct.

The fall in the dollar-sterling exchange on Friday to 4.77 1/16 was reported to be due to false reports having reached New York that Great Britain had decided to postpone the restoration of the gold standard. The rate subsequently recovered to 4.77⅛, but fell again to the former figure on Saturday. French francs eased to 90.45, and Belgian francs to 93.15, but Italian lire were firm at 116.87½.

Both Silver and Gold cheapened on the week at 31⅛d. and 86s. 5d. per oz. respectively.

The Bank Rate is 5 p.ct., to which it was raised from 4 p.ct. on March 5. Bankers' deposit rates are 3 p.ct. The deposit rates of the discount houses are 3 p.ct. at call and 3¼ p.ct. at notice.

CURRENT SALES OF GAS PRODUCTS.

The London Market for Tar, Tar Products, and Sulphate.

London, *March* 30.

There is no alteration to record in pitch in the London market—the position remaining as last reported.

Creosote also is unchanged at from 7⅞d. to 7¼d. per gallon net and naked at works.

Solvent naphtha is in good demand, and supplies are scarce. The price is firm at about 1s. 8d. net per gallon for the 95/160 quality.

Pure benzole and pure toluole are about 1s. 10d. to 1s. 11d. net per gallon.

Tar Products in the Provinces.

March 30.

There is very little fresh to report concerning the markets for tar products.

Although there has been a little inquiry for pitch, there is no alteration in the price.

Creosote remains the same.

Benzole and solvent naphtha are steady.

The average values for gas-works products during last week were: Gas-works coal tar, 29s. 3d. to 34s. 3d. Pitch, East Coast, 40s. to 41s. f.o.b. West Coast—Manchester, 35s. to 36s.; Liverpool, 36s. to 37s.; Clyde, 39s. to 40s.; Benzole, 90 p.c.t., North, 1s. 7¼d. to 1s. 8½d.; crude, 65 p.c.t., at 120° C., 10¼d. to 11¼d., naked at makers' works; 50-90 p.c.t., naked, North, 1s. 2d. to 1s. 3d. Toluole, naked, North, 1s. 7¼d. to 1s. 8½d., nominal. Coal-tar crude naphtha, in bulk, North, 7¼d. to 8d. Solvent naphtha, naked, North, 1s. 5d. to 1s. 6d. Heavy naphtha, North, 1s. 1d. to 1s. 2d. Creosote, in bulk, North, liquid, 6¼d. to 6½d.; salty, 6¼d. to 6½d.; Scotland, 6d. to 6¼d. Heavy oils, in bulk, North, 6½d. to 7d. Carbolic acid, 1s. 6d. to 1s. 7d. prompt. Naphthalene, £12 to £15; salts, £4 to £5, bags included. Anthracene, "A" quality 3d. per minimum 40 p.c.t., purely nominal; "B" unsaleable.

Commercial Gas Company's Increased Price.—The Commercial Gas Company announce an increase in the price of gas from the Lady Day quarter from 8⅛d. per therm to 9⅛d. for quarterly consumers and 10⅛d. to 11⅛d. per therm for automatic meters

Sheffield Gas Company.—The third annual dinner of the Angling Section of the Company's Sports and Social Club was held on Friday, March 20. There were 71 members and friends present; and the Hon. President of the Club, Mr. Ralph Halkett (General Manager and Secretary of the Company), presided.

Gas Meter Manufacturers and Inspectors at Manchester.—On Wednesday, March 25, the Executive Committee of the Statutory Gas Meter Inspectors' Association of Great Britain met at the Gas Meter Testing Station, Manchester, under the presidency of Mr. G. Hume (London). Assembling in the same rooms on Thursday, the inspectors were joined by Mr. H. N. Barrow (Chairman) and most of his colleagues on the City Justices Gas Meter Testing Committee. The party were entertained at luncheon in the Town Hall, at the invitation of the Lord Mayor (Alderman F. J. West), who presided. He said that they had every reason to be proud of the Manchester Testing Station. Sir Henry Cowan moved a vote of thanks to the Lord Mayor. Mr. Braddock and Mr. Templer Depree were present at the luncheon.

Sheffield Illumination Society.—At a meeting of the Society held on March 26, Mr. Ralph Halkett, the General Manager and Secretary of the Sheffield Gas Company, gave a lecture entitled "Gas Topics," treating the subject in a general and popular way.

Lewes Gas Company.—Gratifying progress was reported at the half-yearly meeting of the Company, at which Mr. E. Monk (Chairman) presided. He said that the revenue account showed a profit of £2181 for the half-year. After providing for income-tax, interest on mortgages, &c., the balance of net revenue was £2597. The Directors recommended the payment of dividends for the half-year at the rate of 5 p.c.t. on the original stock, and 3½ p.c.t. on the additional stock. Mr. Monk drew attention to the increase in the sales of gas.

Exmouth Gas Company.—The annual meeting of the Company was held on March 26—Rev. C. R. Carr presiding. A dividend of 7 p.c.t. (less tax) for the past year was recommended on the consolidated ordinary shares. The sales for the year showed an increase of 30,756 therms over the year 1923; this being equal to 6·6 p.c.t. In order to meet the increasing demands for gas, the installation of additional plant at the works, and the extension and enlargement of the district mains were under consideration. The Chairman, in moving the adoption of the report, congratulated the Company on another successful year's trading.

Dartmouth Gas, Coke, and Coal Company, Ltd.—Proposing the adoption of the annual report at the general meeting of the shareholders of the Company, Mr. Harold Adams said the working profit for the year was £2268. The receipts from the sales of gas, coke, and sulphate of ammonia had been maintained, and in each case slightly increased revenue was shown, but there was a reduction of £80 from the revenue for tar. There had been a steadily increasing demand for gas. The distribution of the full dividend of 5 p.c.t. on the second preference shares and 10 p.c.t. on the ordinary shares was recommended; and it was proposed to carry the sum of £500 to the general reserve fund account, and £500 to the reserve fund account for repairs, maintenance, and renewals of plant and works. A reduction of 4d. per 1000 c.ft. would be made from April 1. In order to encourage the permanent employees to provide for their old age, the Directors inaugurated a contributory pension scheme last December.

At a recent meeting of the Whitwell Parish Council, it was decided to ask the local Gas Company for a reduction in the price of gas, which is now 5s. 6d. per 1000 c.ft.

At a whist tournament and dance given at Devonport in connection with the Plymouth Corporation Gas-Works Sports Club the prizes were given by the Chairman (Mr. J. C. Tozer) and Vice-Chairman of the Gas Committee, and the staff of the Gas Department.

The Leeds Corporation Gas Committee recently considered whether or not the price of gas should be increased in view of the past year's working having shown a deficit of £28,000. It was decided that such a course would be inexpedient. The present price is 3s. 9d. per 1000 c.ft.

At a recent meeting of the Morecambe Gas Committee, the Town Clerk reported that the Ministry of Health had sanctioned the following loans: Extension of mains, £3690; carburetted water gas plant £2660; washer, £2572; land, £1285; building for carburetted water gas plant, £1000; and meter, £340.

NOTICES TO CORRESPONDENTS, ADVERTISERS, AND SUBSCRIBERS.

No notice can be taken of anonymous communications. Whatever is intended for insertion in the "JOURNAL" must be authenticated by the name and address of the writer—not necessarily for publication, but as a proof of good faith.

COPY FOR ADVERTISEMENTS for the "JOURNAL" should be received at the Office NOT LATER than TWELVE O'CLOCK NOON ON TUESDAY, to ensure insertion in the following day's issue.

Orders to Alter or Stop PERMANENT ADVERTISEMENTS should be received by the FIRST POST on Monday.

UNDISPLAYED ADVERTISEMENTS; Situations Wanted, Six Lines and under (about 36 words), 3s.; each additional Line, 6d. Situations Vacant, Apparatus Wanted and for Sale, Contracts, Public Notices, &c., 9d. per Line—minimum, 4s. 6d.

TERMS OF SUBSCRIPTION to the "JOURNAL."

		ONE YEAR.		HALF-YEAR.		QUARTER.

EDITORIAL NOTES.

The Legislature and Gas-Electricity Supplies.

THE report of the proceedings on the Horley Gas (Electricity Supply) Bill before the Earl of Clarendon's Committee, is completed in this issue. These proceedings have more importance than merely the local aspect. They have definitely raised in Parliament the improved modern conditions of gas undertakings for economically providing an electricity supply for areas in which there is at present no such service; and, furthermore, they have brought to the knowledge of the Legislature the actual experiences of gas companies who are giving a supply of electricity, and which prove the mythical or groundless nature of the professed notion of opponents that the two services under one administration would not answer. The predictions have not materialized, as is evidenced by what Mr. A. E. Broadberry told their Lordships as to what has happened in the Wood Green area of the Tottenham District Light, Heat, and Power Company, and by Mr. H. J. Randall, regarding the developments of the Yorktown and Blackwater Gas and Electricity Company. The actual accomplishments of administration and management of the dual systems should alone be sufficient to convince Parliament that the absurd contention of electrical opponents, that a community would not be served well electrically by a gas company, has no foundation in fact. Moreover, we submit that in this connection the real question to be considered by Parliament is as to whether competition in these small districts is, from the public point of view, preferable to the economies which it is palpably obvious can be realized by an established and well-organized gas concern. Testimony in this Horley case proves that these economies can be, in the aggregate, of a substantial order; and, therefore, in the interests of a community, it is unquestionably better to permit of the development of the economies than to set up a competition which, to be profitable on both sides, must mean a loss to the communities, having regard to the limited trading potentiality in areas of small population. In such circumstances, every case requires to be considered on its merits. It is no use pointing to the fuel economies of distant large super-stations when it is learned that the transmission costs may represent some 50 to 60 p.ct. of the total cost of delivering electrical energy to the consumers in these small residential areas. A notable feature of this Horley case is that a number of expert witnesses, gas and electrical—whose positions alone warrant the genuineness of their views on the subject, and whose reputations would be in jeopardy were those views not capable of materialization—testified to many economies which must result from the combination of the two services; and we have searched the opposing evidence to find any real destructive criticism, but have failed. Not only was there the evidence in favour by Mr. Broadberry and Mr. Randall, but there was that by Mr. G. M. Gill and Mr. A. Hugh Seabrook; the last-mentioned an electrical engineer who for several years has been making a thorough study of the capabilities of gas undertakings for incorporating in their systems the supply of electricity in areas at present denied the service.

If we combine the points as to economies from the evidence of the four witnesses named, they may be taken generally to be: The existing site of a gas undertaking can be utilized for the generating station, together with railway sidings and other plant for handling material. One administration and management, and the same staff (probably slightly enlarged) can be utilized. The office accommodation and clerical staff can be employed to greater efficiency. Compared with separate undertakings, there would be a saving in rates and taxes; and in respect of work on the district, the same transport facilities would be available, and arrangements could be made so that any work required by both distribution systems could, when breaking-up streets, be carried out simultaneously. Another advantage would be in connection with the raising of capital—particularly by gas companies working under the sliding-scale. In such cases, capital would be obtained at a lower price than in the case of a new company, which had to make its way, and whose future capital-raising power would be detrimentally affected in the event of the concern not proving remunerative to the original investors. What the position of the consumers would be in such circumstances can be well imagined. In these several ways, there must be greater efficiency and economy than could be realized by two comparatively small undertakings run independently. The principal argument for super-power stations is that concentration promotes economy in respect of fuel costs; this quite apart from transmission cost considerations. We submit that, if economy can be realized by the concentration of generation, then it follows that enlarging the scope of a gas undertaking to electricity supply, thus concentrating the work in one establishment, must raise the capacity of that concern for producing greater economy.

In this case, however, we are carried further than these economies which have been put forward from time to time in connection with schemes of combined gas and electricity supplies. In technical circles, the question of the utilization of fuel in the best possible manner, in order to realize in the national interests a greater industrial efficiency and therefore economy, has been discussed for some time. In this particular instance, we have the matter in one form brought before Parliament from the point of view of the gas industry. It is true, and gas engineers do not deny it, that until quite recent times there was a considerable quantity of heat waste from gas-works processes, which there had been no serious attempt to utilize profitably. But modern practice has altered this, by using waste-heat boilers for raising steam; and in this direction, no doubt, there will be considerable developments. It is a contribution to the conservation of fuel; and now the question arises as to the application of waste heat in the case of medium and small-sized undertakings to electricity generation. At the present time, the gas industry is suffering from a slump in connection with its secondary products—coke and coke breeze among them. The problem of disposal is comparatively one of more serious moment to the smaller undertakings than to the larger ones, in view of the fact that the latter have, though producing proportionately more coke, greater opportunities for sale owing to industrial demand. In the smaller concerns, therefore, it would be a fortunate circumstance to be in a position to utilize the poorer part of the home-produced solid fuel, for which there is little local demand, for steam raising for ordinary gas-works purposes, and to put the waste heat from the gas-manufacturing processes to use for the generation of electricity. The opponents appear to be

somewhat dubious as to what can be done in this direction. Actual experience is much better than postulation and doubt, and the experience now of the use of waste-heat boilers on gas-works is of a sufficient order to act as a guide to what can actually be done. There was some attempt on the part of the opponents to belittle this aspect of the case of the Horley Company. In present circumstances, Mr. Gill computes that in the winter months, when electricity would be most required for lighting purposes, the Horley gas undertaking could generate something like 900 lbs. of steam per hour from waste heat; and by Mr. Seabrook it was calculated that in the first year the undertaking could produce from its own surplus heat something like 75 p.ct. of the electrical units which would be required, while the remainder could be met by an internal combustion engine running on gas or oil as preferred. Of course, in the event of the gas sales increasing, the available surplus heat would be augmented. Mr. Seabrook also alluded to those engineers who scoff at the suggestion that gas-works produce sufficient surplus heat to be of any use for the production of electrical energy—in fact, he hinted that some well-known men had described it as a "stunt." The "stunt" is a very substantial and paying practice in gas-works to-day; and in confirmation of this, Mr. Seabrook told of one gas company who are at their largest works putting down a 2000-kw. plant; the whole of the steam used being produced by surplus-heat boilers. The same company are also considering the cost of converting the surplus heat to electricity, and disposing of it to outside users. One or two other large undertakings have experimented, and are prepared to spend a considerable capital sum in proving the idea.

Now that the utilization of waste heat and other fuel supplies in gas-works has been raised to the Parliamentary platform, it must be kept there, and insistence be made as to its recognition as a contribution from the gas industry to the pressing problem of the conservation of our national fuel resources by the co-ordination of the use of fuel, whatever its nature, in public and industrial service. In the controversy that is sure to arise, we would ask the opponents of the gas industry not to do as was done in this Horley case—compare the results of the working of electricity undertakings of large magnitude with the small plants run by gas undertakings in formerly electrically neglected areas. There must be comparison of like with like.

One other point. The Horley Gas Company in this matter of applying for electricity powers have been placed at a distinct disadvantage by the political disturbances of recent years. It was as far back as November, 1923, that public announcement was made, at a meeting of the Gas Companies' Protection Association, of the proposed introduction of a Bill to empower gas undertakings to apply to the Electricity Commissioners for Supply Orders; and the Bill had been under consideration some time prior to that. The Bill is the one which was introduced by Mr. Reginald Clarry; but through the political upheavals of recent times, it has not been able to reach the Statute Book, though there is good chance of its doing so now. The Horley Gas Company delayed their application for supply powers in the hope of realizing them (by the authorization to be conferred by the General Bill) through the Electricity Commissioners. A local Electricity Company were thus able to forestall them. Hence the Bill. But expedition is on the side of an Order; and the Electricity Commissioners succeeded in dealing with the Electricity Company's application, despite the objections raised by the Gas Company, before the latter could get their Bill under way in Parliament. Fortunately, however, the Order has not yet been confirmed. The defence of the Electricity Commissioners for their action is that they had only the one scheme before them, and not the one that was before Parliament. This shows the urgent necessity there is for the Bill introduced by Mr. Clarry (which will co-ordinate procedure in such a case as this) being passed promptly, if gas undertakings are further to assist in serving the community by bringing to bear upon the supply of electricity in suitable areas the facilities and economic advantages they can offer. It is opposed to the public interest (where electricity is required) not to have the supply that can be made available in the most economic manner. The Lords Committee were manifestly of this opinion, inasmuch as they passed the Gas Company's Bill, on the condition that the works were completed to afford a supply in the compulsory area within twelve months from the date of Royal Assent. If the Bill succeeds throughout the rest of its Parliamentary journey, the Horley Gas Company will fulfil without question the obligation imposed upon them.

Gas Fires and Carbon Monoxide.

The attack from Salford on gas-fires owing to supposed carbon monoxide emanations from them into the air of rooms, and thence into the systems of the occupants, has had no effect upon the rate of the growth of popularity of this means of heating. "The proof of the pudding is in the eating;" and new connections prove a wholesome appreciation of the virtues of gas-fires on the part of the public through experience of them. The traducing of those virtues, however, demanded an authoritative research into the matter to confirm or refute the allegations; and this we find has been made by Dr. Leonard Hill, F.R.S., and Mr. T. C. Angus, D.F.C., of the Department of Applied Physiology, National Institute for Medical Research. The results were communicated to the "British Medical Journal;" and, by the courtesy of Dr. Leonard Hill in complying with a request we made to him for permission to reproduce the communication, we are able to give it in later columns. The authority of the experimenters and the results of the severe research will completely set at rest any alarm which may have been occasioned by statements, unsupported by acceptable evidence, as to the probability of chronic poisoning from the inhalation of carbon monoxide escaping from gas-fires, and will thus assist in the work that is being done to clarify the air, and to give an adequate supply of health-yielding ultra-violet rays. It will be noticed that these authorities assert that "carbon monoxide has no poisonous effect other than that of combining with hæmoglobin, and depriving the tissues of oxygen."

In the experiments a standard solution of hæmoglobin was used in a test tube; and the tests were so arranged that air was drawn from the neighbourhood of a gas-fire—a 12-in. one of modern type, used at full capacity. The results of the crucial investigation leave no room for doubt as to the positive immunity of users of gas-fires with flues from risk of carbon monoxide. The experimenters did not rely on a single test or a number under the same conditions, but carried out several in different circumstances. In the first one, air was drawn from the neighbourhood of the gas-fire, and during an hour 760 litres of air travelled over the standard hæmoglobin solution. No perceptible alteration resulted in it. A fresh introduction of the solution was made; and the experiments were continued for another eighty minutes. No change occurred after 1304 litres of air had been drawn over the solution. Thus, in two hours and twenty minutes, more air from the neighbourhood of the gas-fire was passed over the solution than a man would breathe. Air was also bubbled through the solution, with the same results. Further, air was drawn from the proximity of a gas-fire in another room; and there was no indication of carbon monoxide. No evidence of its presence was secured on a windy day. A further experiment was with a gas-fire arranged in the grate of an ordinary open fireplace. Again no evidence of carbon monoxide was found. Other still more severe tests gave negative results. Four flueless stoves placed in a small room with doors and windows closed revealed how little is the amount of carbon monoxide from bunsen flames burning in modern gas-fires.

The tests completely confirm that from modern gas-fires with flues there is no escape of carbon monoxide into the room; but the experimenters held, and there will be general concurrence, that no flueless gas heating stoves should be used in "sealed-up places" where natural ventilation is almost *nil*. In such cases gas-fires with flues should be employed. The tests being of such a severe and delicate character are highly valuable. The full details will be found in the article in later columns.

Powers under the Public Utility Companies (Capital Issues) Act, 1920.

The Public Utility Companies (Capital Issues) Act of 1920 expires on May 20; and the question of the position of companies who have unexercised powers under it has been raised. There has been a division of opinion as to whether those powers may be exercised after May 20. Some have thought they may; others have been of the contrary opinion. The weight of argument is distinctly on the side of the latter. The National Gas Council have to be thanked for placing a case before Counsel and obtaining an opinion against which, it seems to us, it is impossible to advance any argument which would have any validity. The Act had a duration of five years from its Royal Assent; and therefore it may be considered that the Legislature regarded this as the period of stringency, and that the powers they specially conferred should be consummated within that period to be effective. It is obvious that, if the obtaining of the consent of the Board of Trade to the issue of capital under the Act permitted the power to be exercised for an indefinite period, some gas company administrations might deliberately have secured consent for the purpose of over-riding the Special Acts of their undertakings for a longer period than the prescribed quinquennium. Whatever has been completed within the period of five years from the passing of the Act cannot possibly be affected; but whatever has been left undone cannot, in Counsel's opinion, be completed—there must be reversion to the powers under the Company's Special Acts or Orders. In other words, though the consent of the Board of Trade has been obtained, after May 20 the power to do the things to which the Board have consented will have gone. The consent is not the authority for carrying out any of the operations. The Act is the authority; and the Act will on May 20 have run its course. Even though there has been a passing of a resolution by the proprietors to issue capital in accordance with the consent of the Board of Trade, if the capital has not actually been issued at the time the Act expires, all further procedure is arrested by that fact. Counsel is of opinion that the Legislature did not intend to enable companies by these simple expedients to free themselves from the conditions of their Special Acts for an indefinite period. But all that has been done and completed within the terms of the Act during its effective life will continue to be valid. In the case submitted to Counsel, the important question was asked: "Whether, for the purpose of redemption of stock "actually issued as redeemable stock, the company is at "liberty to rely upon the terms of resolution passed "before the date of the Act by which redemption does not "take place until a later period when the Act has ex-"pired?" The reply is: "In my opinion, if the resolu-"tion so provides, the new stock which may be created "and issued to provide money for paying-off the stock "created and issued under the resolution or to provide "substituted stock may be issued as redeemable."

Coal Costs and Output.

The meetings of the Joint Committee of coalowners and miners at which an investigation is being made of the economic conditions of the industry are being held in private; but there is sufficient information published at the close of the conferences to indicate the course of the research. It should become clearer and clearer to the miners' representatives, if it was not sufficiently plain before, that they are responsible to a very large extent for the handicap that has been put upon the British coal industry in comparison with other countries which are growing, or have already grown, into serious competitors of our coal in the markets abroad; and this has a very grave effect upon requirements from British collieries, and therefore upon prices. The very position of the economic conditions of the British coal industry to-day is an invitation to the producers and users of coal in other countries to avoid British coal. Hence the closing-down of the less remunerative pits in this country, and the increasing number of unemployed men, regarding whom there must be a discount from the number when comparison is made with pre-war conditions, seeing that fewer were then employed for a larger output. The last conferences which have been held have been particularly directed to comparisons of costs of production and the outputs per man-shift in this country, on the Continent, and in America, as well as with the similar data for 1914. All through the piece, this country is showing to greater disadvantage in contrast with the statistics from other countries. We have here in the mining industry the shorter working day of seven instead of eight hours, which has had a considerable effect upon the output per man-shift. Furthermore, the wage rate is higher in this country than in others; and, owing to these conditions, the cost of production per ton has about doubled in the years since the commencement of the war. What may seem anomalous is that, in the coal areas where payments to the men are highest, the wage cost per ton is the lowest. This is entirely due to the effect of greater output per man-shift. It is, therefore, perfectly obvious that a vital factor in the cost of production is the man-shift output. The comparisons are proving in every way that British coal is very seriously handicapped in foreign markets through the higher output and the lower cost of production in countries which are in competition with us. Yet singular to state, with these plain facts before them, the miners' representatives decline even to consider the question of increasing the statutory seven-hour day, in order to augment the output per man-shift, and thus do something towards placing the British coal industry in a better position. What they would prefer to achieve is to shorten the hours of work and increase the rates of pay of the miners in Germany, with a view to ruling out the advantageous position occupied by German coal through the larger production at a lower cost per shift. That is an ideal, however, regarding which the German people would have something to say; and they are not likely to agree to their lines of policy in this matter being dictated by the Miners' Federation of Great Britain solely to bring about a competitive equality. Of course, another matter which affects adversely the cost of coal in this country is the increased railway freightage. Figures which have been placed before the Joint Committee show advances ranging from 50 to 88 p.ct. above pre-war rates. The investigations by the Committee are not yet complete; and therefore the Federation have decided to defer a further delegate conference to consider the wage programme and the ending or amending of the existing agreement.

Wembley.

The British Empire Exhibition will be opened on Wednesday, May 6.

"Waste Heat" or "Surplus Heat."

It is contended by Mr. A. Hugh Seabrook that to call heat "waste" which can be put to profitable use is a "terminological inexactitude." What has been known as waste heat on gas-works he contends is heat that has been wasted before it became to be applied to the raising of steam; but as it then comes into account, and increases the thermal efficiency of the gas-works processes, it can no longer be named waste. His view is that "surplus heat" would be a better name for heat which can be usefully applied.

Fixing of Geysers.

The present position regarding the controversy between the National Gas Council and the Metropolitan Water Board as to the fixing of geysers, points to the probability, as no satisfaction can be obtained from the latter, that it will be found desirable to inform the Water Board forthwith that the Council intend advising the Ministry of Health of the Board's refusal, and asking for an inquiry to be held.

Fuel Conservation and Electricity Supply.

The Industrial Group in the House of Commons are considering the question of the proposals for the development of electricity supply in the country; and they have appointed a Committee to go into the matter during the forthcoming parliamentary recess. It is stated that the Ministry of Transport have not yet received the report from the Committee presided

over by Lord Weir; but the problem is one of such complexity and difficulty that the Government do not expect to be able to deal with it this session. The Committee of the Industrial Group ought to have available information as to the power question being a larger one than is covered by electricity supply; that the conservation of coal and the co-ordination of the use of fuel supplies come into its scope; and that the gas industry occupies a place in the matter of power and heat provision, and can and does render important service in this connection and offers opportunities of national advantage, which should not be ignored by any responsible body of legislators.

Which Flicker?

The Paddington Borough Council seriously devoted time last week to a proposal that a Committee should be appointed to consider and report upon the question as to whether it would be a convenience to the public of London if the electric light were made to flicker for an instant at nine p.m. The idea emanated from Sir John Ramsay, who said a time signal of the kind was a feature of life in a town in South Africa where he used to reside. The impossibility of synchronizing a flicker all over London was pointed out. One of the Aldermen wanted to know how the right flicker would be recognized, because the electric lights in his house flickered all night. There was laughter. The idea was rejected.

Low Gas Coke Shipments.

There has been a large decline in the shipments of gas coke. The quantity exported in February was 41,714 tons, which realized £63,807, or an average of £1 10s. 7d. per ton. In February of last year, 105,227 tons were sent abroad; and in the same month of 1923, 106,233 tons. The values were: 1924, £183,323; 1923, £152,927. Taking the two months of the year, the exports amounted to 105,520 tons; the value being £163,685. In the corresponding period of 1924, 249,629 tons were shipped of a value of £432,653. The figures for 1923 were 200,688 tons; and the value £284,164. The metallurgical coke trade has also experienced a marked fall. The exports last month amounted to 102,083 tons, as compared with 156,142 tons in 1924, and 146,662 tons in 1923. In the two months of the year, the shipments of the metallurgical variety were 240,169 tons; 1924, 420,395 tons; 1923, 327,513 tons—the values being respectively £326,111, £844,172, and £529,280.

Exports of Tar Products.

Less benzole continues to leave the country. The quantity exported in February was down to 2252 gallons, as compared with 223,429 gallons in February, 1924. In January and February, 62,480 gallons was the total shipped; and this compares with 239,503 gallons in the corresponding months of last year. Of naphtha 5019 gallons were sent abroad last month, as against 31,628 gallons in February, 1924. In the two months only 7432 gallons were shipped, as contrasted with 45,159 gallons in 1924. Compared with January, February saw a large increase in the shipments of tar, oil, creosote, &c.—the figure being 4,097,259 gallons, compared with 1,640,009 gallons in February, 1924. The total for January and February was 7,765,666 gallons, which is more by 486,216 gallons than in the same two months of 1924.

Sulphate of Ammonia Exports.

In February, 27,975 tons of sulphate of ammonia were sold for overseas use, as compared with 24,648 tons in February, 1924. Taking January and February together, 60,409 tons were exported, as against 60,937 tons in the corresponding period of 1924. In the two months this year, Spain and the Canaries have been the best customers with 21,425 tons, compared with 12,784 tons in 1924. Japan comes next with 12,282 tons, but in the same period of last year that country bought 24,206 tons. The Dutch East Indies was in the two months a buyer to the amount of 10,519 tons, which is nearly 3500 tons better than in the same period of last year. The markets fluctuate, but the total for the two months (as seen above) is only about 500 tons behind 1924, which is a difference that may in a period of two months easily occur in business and shipments abroad.

Labour Alliance.

The scheme of the Miners' Federation for an alliance between themselves, the engineering, railway, transport workers and other unions does not appear to be making rapid headway. Discussions are still proceeding; and later on there is to be a combined conference of all the unions. One difficulty is that making common cause to support the programmes of some of the unions would inflict injury on the industries that give the members of other unions employment. However, even that firebrand, Mr. A. J. Cook, the Secretary of the Miners' Federation, says he will be no party to leading the miners out alone. The Industrial Secretary of the National Union of Railwaymen (Mr. C. T. Cramp) says he will not be prepared to enter into any binding alliance without the full consent of the rank-and-file. He is wise. Schemes which emanate from the Communists should be scrutinized with the utmost care in order to ascertain to where they may lead, if accepted. We are inclined to think—in fact, we know—there are many members of trade unions who resent the influence the Communists are wielding in the policies of their organizations.

PERSONAL.

The General Managership and Chief Engineership of the Commercial Gas Company.

In consequence of the responsibilities arising out of the death of his father, the late Mr. H. E. Jones, Mr. Stanley Hunter Jones, M.Inst.C.E., has resigned his position as Engineer and General Manager of the Commercial Gas Company as from the 30th inst. The Directors of the Company have elected Mr. Jones to a seat on the Board as from May 1 next, and have appointed Mr. Frederick John Bradfield, F.C.I.S., the present Secretary and Accountant, to be General Manager and Secretary, and have also appointed Mr. Archibald Edgar Williams, A.M.Inst.C.E., at present Works Engineer of the Stepney Station, to be Chief Engineer of the Company.

This month Mr. John Bond, O.B.E., completes 21 years' service as Manager and Engineer of the Southport Corporation Gas-Works; and in honour of the event a series of presentations was made to him last week. On Wednesday the staff and men at the works paid their tribute; and on Friday the staff and men of the distribution department made fitting recognition of the occasion. At the works gathering there were about 100 employees present. Mr. T. Cook (Deputy Engineer) occupied the chair, and was supported by Alderman E. Trounson, J.P. (the Chairman of the Gas Committee), Councillor J. E. Hindle (the Vice-Chairman), Mr. T. Halsall (Commercial Assistant), and Mr. Russell Johnson (Chief Clerk). Mr. Cook, Mr. Halsall, and Mr. Johnson had acted as Chairman, Secretary, and Treasurer respectively in getting together the necessary funds for the presentation. The Chairman said the meeting had been called that they might all have the opportunity of showing their appreciation of their Chief. The technical staff fully appreciated that Mr. Bond was always ready to give a hand to the junior members, to assist them to rise to the higher rungs of the ladder. The men who had left their works to take up senior and junior appointments in other works owed their all to Mr. Bond for his valuable help. They were very pleased to have Mrs. Bond with them that afternoon, and he was sure she must feel very proud of the occasion. Mr. Halsall reported that he had received telegrams of congratulations to Mr. Bond from the following gentlemen who had previously served at Southport under him: Mr. J. E. Blundell (Gas Engineer, Carlisle); Mr. S. E. Whitehead (Assistant Gas Engineer, Portsmouth); and Mr. Leslie Smith (Assistant Gas Engineer, Macclesfield). Mr. Russell Johnson made the presentation; the gifts consisting of a gold fountain pen engraved, a smoker's cabinet, and an attaché case. Mr. Johnson congratulated Mr. Bond, and assured him of the good feeling that had prompted the gifts. Alderman Trounson declared that he never envied a man more in all his life than he did that afternoon. Mr. Bond had that which all men prized beyond money. Mr. Bond said he felt overwhelmed with his reception. He appreciated greatly their friendship, and sincerely thanked them for the lovely presents. Mr. Philip H. Christian (Outdoor Superintendent) presided over the second function, at which, after further interesting speeches, Mr. Samuel Rigby (the oldest employee of the distribution department) asked Mr. Bond's acceptance of a choice dinner gong. Mr. Bond acknowledged the very handsome present.

The Directors, staff, and employees of the East Hull Gas Company have presented Mr. Boswell George Jalland, J.P. (the Chairman), with a suitably inscribed gold cigarette box, as a mark of their esteem and goodwill, on his completion of

fty years' service as a Director of the Company. The pre-entation was made by Mr. George Taylor, one of the oldest mployees, who was supported by Mr. Richard Nelson (the eneral Manager and Engineer) and Mr. Charles M. Jackson a Director) in voicing the affection and esteem in which the Chairman is held by all. Mr. Jalland expressed great pleasure n the cordial relations which have always been maintained be-ween the Company and the employees.

Mr. John W. M'Lusky, Engineer and General Manager of he Glasgow Corporation Gas Department, and Mrs. M'Lusky, re sailing from Glasgow, on the 24th inst., by the C.P.R. .s. "Mountlaurier" for the United States. Mr. M'Lusky will isit upwards of a dozen important gas undertakings, and finish n New York, where he will, if arrangements are fulfilled, meet Ir. L. Hislop (late of Uddingston), who is on a world tour vith his wife and daughter. It is expected that the party will eturn together to Liverpool in the s.s. "Adriatic," *ex* New ork June 20. All good wishes for an informative and bene-cial tour.

Newly elected members of the Society of Chemical Industry nclude Mr. Frederick J. Bywater, of Alnmouth, Northum-erland; Mr. Frederick C. Bishop, of the Blackwell Colliery oke Ovens, near Alfreton; and Mr. Frederick T. Hatswell, fitchell Main Colliery Coke Ovens, Wombwell.

At the recent annual meeting of R. & J. Dempster, Ltd., of lanchester, it was decided to appoint additional Directors to he Board. Mr. H. S. Knight, General Manager, Mr. J. W. cott, Outside Chief Engineer, and Mr. W. R. D. Perkins ere elected.

Mr. R. G. Luxon, Engineer and Manager of the Launceston as Company, is shortly vacating that post in order to take up n appointment in Guernsey.

Mr. John Whitaker, who has just retired from the post of ndoor Superintendent of the Bradford Corporation Gas Depart-ent, after over forty years' service, and has been the recipient f various presentations from the Gas Committee and his col-agues in the department, was last week made yet another pre-entation, this time from the members of the Bradford Muni-ipal Golf Handicap. It was a solid silver flower vase, and the unction was presided over by Mr. E. J. Sutcliffe, Deputy Gas ngineer, who, like Mr. Whitaker, is a keen golfer. The pre-entation was handed to Mr. Whitaker by Chief Officer J cott, head of the City Fire Brigade.

Mr. R. B. Hodgson, of Stockton, has joined the Board of he Whessoe Foundry and Engineering Company, Ltd., of Dar-ington, and been appointed Managing Director. Mr. Hodg-on is well known in the gas industry and in general engineer-ng circles of this country, and has for some years been Director nd General Manager of Messrs. Ashmore, Benson, Pease, & o., Ltd., of Stockton-on-Tees.

Mr. W. E. Brock, late representative for Messrs. James Milne Son, Ltd., has joined the staff of the Wellington Tube Works, td., of Great Bridge, Staffs., as Outside Representative.

OBITUARY.

A most impressive funeral marked the interment on Satur-ay last of Mr. Henry Ellison, founder of the firm of Henry llison, Ltd., well-known in the gas, chemical, mining, and llied industries. Seventy-seven years old, the deceased gentle-an was in his customary good health up to last week, when e had a seizure. A man of remarkable business judgment, Ir. Ellison founded or assisted many enterprises, in addition o his own firm, which was started in a humble way in Cleck-eaton. Among many concerns with which Mr. Ellison was rominently associated, mainly as Chairman of Directors, ere the following Gas Companies: Royston, Brodsworth and istrict, Beighton, Dinnington, Maltby, Bawtry, Whitwell, and horne.

The death took place on April 4, at the age of 77, of Mr. William Corbett, of Cherry Lea, Bromsgrove. At the time of is death he was a Director of the Bromsgrove Gas Company.

Mr. A. B. Beetles, Outdoor Superintendent at the Lytham-t. Annes Corporation Gas-Works, died suddenly on April 3.

Sympathy is extended to Mr. J. P. M'Crae (Assistant ngineer to the Derby Gas Light and Coke Company), who has ad the misfortune to lose his mother, who was the widow of Ir. John M'Crae, for some time Engineer and Manager to the undee Gas Commissioners. Mrs. M'Crae died at her resi-ence, "Rosemount," Crail, on the 26th ult.

Southern Association Bournemouth Visit.—We learn from the on. Secretary (Mr. H. C. Smith) that the visit of the Southern ssociation of Gas Engineers and Managers to the works of he President (Mr. Philip G. G. Moon), at the invitation of the hairman and Directors of the Bournemouth Gas and Water ompany, will take place on Friday, June 5. A joint meeting the Districts will be held the previous afternoon in the ime town.

THE COKE COMPETITION.

One Thousand Pounds in Prizes.

The full particulars of the Coke Competition appeared in our issue for Feb. 18, together with the conditions, and explanatory and editorial articles. The £1000 to be distributed in prizes has been placed in the hands of the Editor of the "Journal" by the Woodall-Duckham Companies, solely with the view of developing the interests of the gas industry by accumulating all knowledge, results of research, and suggestions which will assist in raising the status of coke, qualitatively and commercially. With this act of generosity, the Companies referred to retire from all participation in the organizing of the competition or in adjudicating upon the papers which will be submitted. The whole matter was at the outset placed completely in the hands of a Committee, composed of Mr. A. W. Smith, General Manager and Secretary of the Birmingham Corporation Gas Department, Mr. W. B. Leech, Engineer of the Beckton Gas-Works (Gas Light and Coke Company), and the Editor of the "Journal" (Mr. A. F. Bezant).

Briefly it may be stated that the competition is divided into three Sections:

COKE PRODUCTION.

SECTION I.—A paper dealing with the Manufacture of Coke of the most suitable qualities for Domestic and Industrial Purposes; as far as possible including the Cleaning and Blending of Coals, or Coals and Coke, their Carbonization, and the Quenching of the Coke—due regard being paid to the economic requirements of gas production and the value of the other secondary products.

COKE PREPARATION.

SECTION II.—A paper on Coke Preparation, to include Screening, Grading, Conveying, and Storing of Coke.

SALE AND UTILIZATION OF COKE.

SECTION III.—A paper on the Sale, Distribution, and Use of Coke, both for Domestic and Industrial Purposes, at Home or Abroad.

The papers must be separate for each Section, but any competitor may enter for one or more Sections.

PRIZES.

The following Prizes will be awarded:

SECTION I.		
First Prize	£200	
Second Prize	75	
Third Prize	50	
Twelve Prizes of	10	each.
SECTION II.		
First Prize	£100	
Second Prize	50	
Third Prize	25	
Ten Prizes of	10	each.
SECTION III.		
First Prize	£100	
Second Prize	50	
Third Prize	25	
Ten Prizes of	10	each.

The competition is open to the men of the gas industry of the whole world, and to others who have anything valuable to say—always bearing in mind that gas is the staple commodity of the industry. Thus there is no restriction as to competitors. Those to whom the prizes may not appeal, but who have anything of value which they can contribute, the Committee earnestly ask them to do so in the interests of the industry, the highest welfare of which all associated with it in responsible positions should have at heart.

There are rules to be observed in submitting papers; and they will be found clearly set forth in our issue for Feb. 18.

If any further information is required regarding the competition, a letter addressed to the Editor of the "Journal" will secure it, providing the points are specified on which the additional particulars are desired.

Riveter for Holder Cups.—The Hanna Engineering Works, of Chicago, have recently placed upon the market a riveting machine designed specially for use in connection with gasholder cups, which consist of a channel and two plates—one wide and one narrow. The plates are riveted on the flanges of the channel. The cup section itself is a cumbersome piece; and the riveter being the easier of the two to handle, is used in portable form. The riveter should be as light as possible, and with this in mind a special frame was developed known as the "true truss design." The machine has a 42-in. reach, and a 12-in. gap. The cylinder diameter is 10½ in., and it is capable of exerting 30 tons on the dies at 100 lbs. air pressure. In this machine is incorporated the Hanna patented mechanism, which develops a predetermined pressure uniformly throughout the last half of the piston stroke, or the last ½ in. of rivet die travel.

SAFETY OF GAS FIRES IN REGARD TO CARBON MONOXIDE.

By Leonard Hill, M.B., F.R.S., and T. C. Angus, D.F.C.
(From the Department of Applied Physiology, National Institute for Medical Research.)

[Published in the "British Medical Journal," and reprinted by permission of Dr. Leonard Hill.]

At times alarm has been expressed in connection with the use of gas fires as to the probability of chronic poisoning arising from inhalation of carbon monoxide. In a pamphlet published recently by a medical officer of health of a large city, and circulated at the recent Smoke Abatement Conferences, this view was put forward definitely, but without supporting evidence.

We thought it worth while, then, to carry out a few experiments to see whether we could put this fear at rest and remove any antagonism against the wider use of smokeless fuel which is necessary in order to secure freedom from smoke pollution of the air and an adequate supply of the health-giving ultra-violet rays. Carbon monoxide has no poisonous effect other than that of combining with hæmoglobin and depriving the tissues of oxygen.

Blood taken and diluted to 1 in 200 parts of distilled water afforded a standard transparent solution of hæmoglobin. When placed in a narrow test tube of the Gowers-Haldane hæmoglobinometer and viewed against a white background by daylight, it appeared yellow-red, as is characteristic for this dilution and width of containing tube. Saturated with carbon monoxide by shaking with coal gas, the tint of the solution under the same conditions is carmine. Partial saturations vary from the yellow-red very slightly tinted with pink up to the full carmine colour.

Experiment 1.—A balloon was filled with a measured volume of air by means of a blower fan and meter, and enough coal gas introduced to give 1 in 1000 parts of air. A sufficiency of the standard solution of haemoglobin was placed in a tube 6 in. long and 1 in. in diameter, which at each end was closed by a cork through which a narrow tube was inserted. The tube was held horizontally so that the solution of haemoglobin lay from end to end along its floor exposed in a shallow layer to air above, which was drawn through the tube in a steady stream through the narrow tubes, one of which was connected to the balloon, while the other was suitably attached to a suction fan driven by an electric motor. During half-an-hour 670 litres of air from the balloon was drawn over the haemoglobin solution. On comparison with the control solution (kept in pure air) this solution gave a just perceptible change in tint, indicating a very slight formation of carbon monoxide haemoglobin.

Experiment 2.—Two parts of coal gas per 1000 of air were then put into the balloon, and the experiment was repeated. After thirty minutes a slight but quite definite carmine tint was clearly seen on comparison with the control.

Experiment 3.—The experiment was now arranged so that air was drawn from the neighbourhood of a gas fire, a position being chosen where a person's face would be who sat down by the side of a fire in order to warm his legs. The gas fire, 12 in. wide, was of the modern type and properly flued, being built into a chimney, and was turned full on. During one hour 760 litres of air were drawn over the standard haemoglobin solution. No perceptible change in tint resulted. The solution was reintroduced, and the experiment continued for another eighty minutes. No change in tint resulted after 1304 litres in all had been drawn over the blood. A resting man breathes on the average about 6 to 7 litres of air a minute, or the above amount in a little over three hours. More air was, then, drawn over in the two hours and twenty minutes' observation than a man would breathe.

Experiment 4.—An experiment was arranged so that air, in place of being drawn over, bubbled through the standard haemoglobin solution contained in a flask. In this case the rate of ventilation was about 150 litres an hour. The air was drawn from the neighbourhood of another gas fire of similar type and properly flued, but in a different room. No indication of carbon monoxide escaping into the room was found in this case.

Experiment 5.—This experiment was repeated on a windy day, when possibly there might be some down-draught in the flue. No evidence of carbon monoxide was obtained.

Experiment 6.—The experiment was repeated on a gas fire arranged in the grate of an ordinary open fireplace; the fumes from the fire escaping up the open chimney above the fire. No evidence of carbon monoxide escaping into the room was obtained.

Experiment 7.—The experiment was repeated with this variation, that a door adjoining the gas fire was set open to create a draught between door and window across the neighbourhood of the fire. The result was negative.

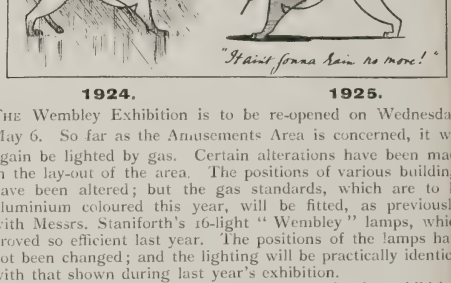
Experiment 8.—The experiment was repeated and varied by placing a small electric fan to blow across the gas fire to where the inlet to the sample tube lay. The fan blew across the warmed strata of air which lay in front of the fire, and this warm air was perceptible to the face when placed near the inlet tube, and gave one at once a stuffy feeling. No evidence of carbon monoxide escaping into the room was found even in this extreme condition of artificial side draught, which might be expected to blow fumes into the air.

Experiment 9.—To make the conditions as severe as possible, four *flueless* gas stoves of various types were placed in a small room about 12,000 c.ft. in capacity, and the door and window closed. The stoves were lit, and a mouse was placed on the table in the room. After two hours the temperature of the air at head level was 100° Fahr. dry bulb, and 87° Fahr. wet bulb; and on entering the room, one felt it at once stuffy. The mouse's blood showed 16½ p.ct. of carbon monoxide haemoglobin.

The difference between the inside and outside temperatures set-up enough natural ventilation through the crannies of door, window, and up the chimney to prevent very serious contamination of the air with carbon monoxide in this extreme case, showing how small is the amount of this gas arising from bunsen flames burning in modern gas fires. The touch of heated air to the face on entering such a room is unpleasant, while the breathing of the heated air, which contains traces of sulphur acids, congests the nose and gives a stuffy feeling. At the same time, cold feet may arise from the draught; cool air entering beneath the door. Gas fires should, then, always be properly flued.

No flueless gas burners or stoves should, of course, be used in *sealed-up* places where natural ventilation is almost *nil*. In such sealed-up places carbon monoxide may collect in dangerous amounts if cold surfaces are brought in contact with bunsen gas flames so as to check combustion.

BRITISH EMPIRE EXHIBITION



1924. **1925.**

The Wembley Exhibition is to be re-opened on Wednesday, May 6. So far as the Amusements Area is concerned, it will again be lighted by gas. Certain alterations have been made in the lay-out of the area. The positions of various buildings have been altered; but the gas standards, which are to be aluminium coloured this year, will be fitted, as previously, with Messrs. Staniforth's 16-light "Wembley" lamps, which proved so efficient last year. The positions of the lamps have not been changed; and the lighting will be practically identical with that shown during last year's exhibition.

With regard to the use of gas generally in the exhibition, practically the whole of the cooking at all the restaurants, cafés, &c., will be done by gas. There will be additional restaurants; and in these a very full gas equipment is being installed. Some of the other alterations which are taking place are: Larger supplies to Messrs. Carsons, who will be installing a Bonecourt boiler of considerably greater capacity; additional kitchen to Ceylon, where gas is being exclusively used for all hot-water and cooking; further supplies to British Guiana, and to Messrs. Barnand's, Messrs. Poppett's, &c., in the Palace of Industry, as well as to the Anglo-Indian section; and considerably greater supplies to Messrs. Baker Perkins, who are installing bigger ovens this year. A new service has been run to the South African exhibit, together with a number of other supplies in various places.

The original gas installation—including the 12-in. circuit main, with two station meters—still remains; and it is expected that the amount of gas used in the exhibition this year—subject, of course, to the prevailing conditions of weather—will be as much as, probably greater than, the requirements of 1924. All this apart from the Gas Exhibit, to which several references have appeared in the "Journal."

Coke-Oven Gas in France.

In a communication recently made to the Société de Chimie Industrielle, M. C. Berthelot draws attention to the fact that the French production of metallurgical coke, which amounts to about 3 million tons a year, corresponds to only one-quarter of the national requirements. The use of coke-oven gas for town use, he says, is therefore to be encouraged. He compares its use in France with that in Germany, where from 1903-21 the consumption increased from 500,000 to 31,000,000 cub.m.; in the United States, where the quantity has advanced from 607 millions in 1910 to 6075 millions in 1920; and in Belgium, where the towns of Brussels, Liège, Ghent, Mons, and Ostend are supplied wholly or partially with coke-oven gas. The gas should be purified before it leaves the works. The reason why this is not the present practice, he suggests, is because of the expense of oxide purification; and he thinks it would be better if wet purification was resorted to. The latter system is applied in 26 American installations for the daily treatment of more than 8 million cub.m. of gas. This process is to his mind an improvement—technically and financially—on oxide purification.

ELECTRICITY SUPPLY MEMORANDA.

Facts and Fancies.

The conferences on Electrical Salesmanship, as arranged by the Electrical Development Association, have ended for the present session. The last one was devoted to the consideration of a paper by Mr. R. Hardie, of the Glasgow Corporation Electricity Department, on the "Development of Electricity Supply in Residential Areas." In large part the paper advocated, relying upon recent experience in Glasgow, the adoption of hire-purchase for the wiring of houses. Although the electricity supply industry will not openly acknowledge the fact, they have had to resort—having obtained the easiest gained business—to countless methods for the purpose of influencing other people to adopt, even in a small way, the use of their commodity. This fact is rather a contradiction of the claims as to the pre-eminent virtues of electricity for domestic lighting and heating, though, as consumers well know, the really pre-eminent characteristics of electricity supply, particularly for heating and cooking, are the costs from installation to daily running. It appears that the main object in Glasgow of adopting the hire-purchase of wiring installations is to get in the thin edge of the wedge with lighting, and subsequently to attempt to effect the conversion of householders to the uneconomies of electric heating and cooking. Mr. Hardie says that in Glasgow they have calculated that the allotment of household expenditure in an average five-apartment house is £3 for electric lighting per annum, £6 for gas, and £10 for coal. We are obliged to Mr. Hardie for this allocation, in view of the fact that gas is only responsible for twice as much expenditure as electric lighting. Seeing that the application of gas in such a house is for cooking purposes and probably occasional room heating, and that the hotplate of the gas-cooker is very largely used for hot water provision, an expenditure of £6 a year, or 2s. 3d. per week, which is less than an average of 4d. per day, is something upon which we can pride ourselves, having regard to the extensive use which is made of the gas-cooker from early morning to last thing at night. The hotplate of the electric cooker would refuse to perform similar services without running away with a considerable amount of thermal energy. It is clear, too, that for electric lighting something like saturation point has been reached among householders who are willing to bear the cost of a wiring installation. Hence it is that it is necessary, in order to penetrate the strata beneath, for electricity departments to indulge in schemes whereby the wiring can be carried out by means of easy payments. The great difficulty in this connection is that even hire purchase will persuade but few tenants to adopt electricity, inasmuch as the wiring for which they are paying will, if in fit condition to be used when they leave the house, become the property of the landlord. Mr. Hardie describes this realization of new custom in fresh strata as "the problem" of obtaining new customers for lighting; and he admits that this is a most pressing task. We are not grieved to hear it.

Littleness.

To the reader there appears to be something pompous in Mr. Hardie's remark: "I have acted on the assumption that my work is to sell electricity without regard to the effect on the gas undertaking." How dreadful! We have not the slightest doubt that, without shouting it from the housetops, the men connected with the sales of gas in Glasgow are animated by precisely the same feeling of developing the sales of their commodity without regard or affection for the Electricity Department; and they are doing it. But we must protest against the remark of this electrical salesman: "Yet to-day, when electricity is at last beginning to live down the gross mendacious misrepresentation of the opposing vested interests and is making headway, there is a change of front impending." Mr. Hardie cannot know the history of things or he has been blind, or must possess an incapacity for discriminating between mendacity and truth if he does not know that the mendacity and slander that the gas industry formerly received from persons representing electric interests were such that even prominent men in that industry protested against the extravagance of language and claim. In addition to hyperbole, there is humour in a succeeding point which Mr. Hardie presents. He says: "If, as has been proved, gas need not for any purposes be laid into a modern dwelling-house, why incur further capital expenditure in laying gas mains and piping houses for a service which no one outside the gas industry will tolerate?" There was surely no occasion for the "if," seeing that Mr. Hardie is of opinion that gas is a service which no one outside the gas industry will tolerate. Did ever anyone read such rubbish, in view of the magnificent increases in gas consumption that the gas industry has been experiencing the last few years? These increases have not been obtained within the gas industry, but are produced by the patronage of the householding population of the country without identity with, or interest in, the industry in any way other than that of being glad to have the service of a labour-saving heating agent which is far more economical than anything electricity can offer them. Mr. Hardie's knowledge of even the elementary economics of the matter appears to be somewhat deficient. If this is the sort of thing that is to be presented at these Salesmen's Conferences for educational purposes, then it is a great pity, in the interests of an important industry such as that of electricity supply. These conferences are held under the auspices of the Electrical Development Association. We should like to know whether Mr. Beauchamp subscribes to the statements to which we have called attention. However, what the population of the country really thinks of the two commodities is well shown by Mr. Hardie himself, when he states that a year ago the Glasgow Electricity Department had 14,500 domestic consumers, while the Gas Department had upwards of 200,000 whose premises were lit by gas—electricity representing roughly 8 p.ct., with the average for London and the United Kingdom about 10 p.ct., or at most 15 p.ct.

The Scheme.

The wiring hire-purchase scheme outlined by Mr. Hardie has not been in existence many months. It offers to the householders the wiring of their houses with the payment spread over three years. It is explained in the paper that the majority of Glasgow people reside in what are known as tenement houses with, in each of them, eight to twelve possible consumers, who can be supplied from one service cable. Such a condition is naturally attractive from the supply authority's point of view. The Department's branch terminates at a point about 3 ft. from the entrance; and from there they endeavour to get the proprietor to instal a main rising cable to the top flat, complete with junction boxes on each flat, from which ultimately all the tenants may, should they so desire, obtain their supply. The usual cost of this work is £9. There the proprietor finishes his part. In the six months ending February, rising cables were installed at the proprietors' expense for upwards of 200 tenement houses, which means that facilities are now available for something like 2000 tenants "when they so desire." Of course, the interior wiring has to be carried out at the tenant's own expense; and there the trouble begins for the Department, in view of the fact that the tenant, being undecided as to his length of tenure, and disinclined to spend money on wiring another person's property, is not easily persuaded to incur the outlay. Nevertheless, Mr. Hardie states that, in the six months, 650 tenants have wired their houses, the majority of whom would probably not have done so in the absence of the scheme. Having regard to the population of Glasgow, Mr. Hardie acknowledges that this is an insignificant number, but he does not think it is altogether discouraging, having regard to the obstacles. In his opinion, too, it is probably correct to assume that the first 1000 consumers are the most difficult to obtain in a novel scheme. We do not think that is the common experience. Generally speaking, as has been found in connection with electric cooker installations, the first few hundred people who are attracted by novelty are easier to secure than subsequent hundreds; the tendency is for the new connections to tail off. As to tenant's cost: For a two room and kitchen house with five lights and two plugs for connecting electric fires (which can be hired), the price is £8 10s. if cash is paid, or £9 10s. if payment is spread over three years, in twelve quarterly amounts. For three rooms and kitchen, with six lights and two plugs for electric fires, the cost is £10 if paid in cash, or if spread over three years £11 6s. For four rooms and kitchen, with seven lights and two plugs for electric fires, the cost is £12 if paid in cash, or if payment is spread over three years £13 14s. These figures include cord pendants and lamps. If three-light or other superior fittings are desired, these are sold as an extra by the contractor. That is the scheme, and while we congratulate the Electricity Department on what has so far been done with wiring hire-purchase, it must be recognized that the conditions of Glasgow are not commonly found elsewhere; and it is very doubtful whether future experience as to the accretion of this class of custom will bring the same degree of satisfaction. Pretty certain it is that the class of tenants in these houses will not be able to afford much in the way of electric heating and cooking.

Which is the Jumpy Therm?

The Weymouth Corporation have been holding an electrical exhibition. The Gas Company have been doing some excellent propaganda work in the local papers and otherwise for their primary commodity. The electric exhibition is intended to be an answer to this. At the opening of the exhibition, some things were said which have to be proved; and a good many things were left unsaid, which shows discretion on the part of the electrical purveyors. The business propaganda of the Gas Company was referred to at the opening of the exhibition by Alderman T. J. Guppy, the Chairman of the Electricity Committee; and he attributes it to the "jumpy therm." A local newspaper in a headline alluded to the Alderman's "humour," which suggests that we ought to laugh over the "jumpy therm." Perhaps it will surprise the Alderman to learn that we did so, because it is positively certain that both the therm and the Gas Company's propaganda have given him the "jumps." Another matter over which we smiled was the omissions in his speech. One thing he did not tell the public was that it requires 29 units of electricity to equal the potential

heat energy in one therm. The price of electricity for heating and cooking in Weymouth has been reduced to 1½d. per unit; and the price per gas therm is 10d. Therefore, to obtain an equivalent amount of heat, 3s. 7½d. must be expended on electricity, as against 10d. for gas. Why did not Alderman Guppy state this? He might also have illustrated the matter another way. At 10d. per gas therm, 15,000 B.Th.U. can be purchased for 1⅓d. An electrical unit being equal to 3420 B.Th.U., 4⅓ units would have to be purchased at an expenditure of 6⅓d. to equal the potential heat purchasable for 1⅓d. by gas—in other words, 1⅓d. spent on gas will give 15,000 B.Th.U., as compared with 3420 B.Th.U. by electricity. The Alderman will see that in these differences there is an advantage on the side of gas which must give the Electricity Department violent "jumps" if they want to get hold of a substantial cooking and heating load; and the "jumps" would extend to the consumers when they received their accounts for current consumed for these purposes. When the good people of Weymouth consider those things which Alderman Guppy did not disclose to them, they will want to know what he meant by the words: "An exhibition of electrical energy for cooking and other things as come within the region of everyone." The passage is not happily phrased, and it is untrue. Also what was the justification for his saying: "We will leave it to the demonstrators to show you we can cook and give you other facilities in better form so that the people of Weymouth can enjoy the benefit of electricity." There is more to be learned by the user about electrical operation for any heating purpose than the mere employment of the appliances. Experience is apt to produce nasty shocks—of a monetary and time absorbing character. The appliances may be very fine to look at; but it is impossible to get more heat out of the electrical unit than it contains. Such generalizations as were used by Alderman Guppy in his speech do not prove anything.

Imitation.

Some electrical journalists ought to be on the staffs of papers which purvey frivolity of varied quality to their readers, rather than be associated with technical papers. Imitation, we are told, is the sincerest form of flattery. If this be true, then the writer of "Cooking and Heating Notes" in the "Electrical Times" thinks that compliments are being showered upon domestic electrical appliances by the gas rivals. Naturally, there has been interest and amusement in investigating what is said in support of this. It is found that the writer of the notes in question is as lamentably ignorant regarding the history of gas appliances as he is incapable of making proper comparisons between gas and coal heating, as was seen in our editorial columns on March 18, under the heading of "Electrical Arithmetic." Among the supposed feats of emulation he mentions the pneumatic gas switch, the gas "bowl type" fire, and the gas imitation coal fire. As to the last-named, they were on the market long before imitation electric coal fires were there, which are one of the biggest jokes ever played upon the public by an industry which seems to be fond of practical joking, and playfully calls it "business." As to the pneumatic switch and the gas "bowl-type" fire, these are merely instances of the large range of adaptability possessed by gas. But the writer in our contemporary, unfamiliar with the history of things, charges the gas industry, among its more recent efforts, with the enormity of being copyists in respect of the outside heating of ovens. This is really funny, seeing that some of the earliest types of gas-ovens were heated that way; and it must be twenty years ago now that externally heated gas-ovens were on the market, and some substantial ones were installed in hotels, clubs, and other places in London. But we must excuse the electrical novices in these matters if they in their eagerness and ignorance make mistakes of this kind. It may seem curious to our electrical friend that the public never took very kindly to externally heated ovens; and with all the silly talk of the electricians as to gas fumes, the public, with comparatively few exceptions, stick to the internally heated oven. The ignorant accuser of imitation says that gas has copied external heating with a view to secure the same hygienic conditions as obtain in electric cooking. Now what does he mean by that? The most unhygienic conditions in cooking are to be found in an unventilated oven, where meat is being cooked in an atmosphere saturated with its own emanations. This must be a particularly unhygienic state when the meat retains the flabby condition to be found in a closed oven with a supersaturated atmosphere, and an unusually low cooking temperature.

Further Piracy.

Then this vain pretender to knowledge has some idea that thermostatic control has been adopted to deal with the variations of heat due to fluctuations of pressure in the mains. Thermostatic control has been in use many years in connection with gas-heated hot water apparatus; and its application to ovens is simply an extension of service from one form of apparatus to another, but it is only found in certain modern superior types of gas cooker. The idea is not by any means to deal with the supposed fluctuation of pressure; but the control can be set to any desired temperature—giving a temperature range of incomparable value contrasted with electricity—and, when that is reached, the gas supply is maintained at a level which will ensure the same temperature continuing as long as desired, despite heat losses through radiation, conduction, convection, or variations of atmospheric temperature external to the oven. Really laughable is the colossal assumption which the writer in our contemporary possesses as to the copying there has been by the gas people of electrical apparatus. Really the boot is on the other leg. To the electric cooker he says may also be attributed the separation of the hotplate and grill from the oven. Such separate construction may be found illustrated in very ancient catalogues of gas-cooking apparatus. But worse still—electric competition is credited with "frantic endeavours" to improve the "appallingly" low efficiencies of the gas hotplates. Does this strangely imaginative individual suppose gas investigation and progress would have stood still had it not been for electrical competition? The most pronounced ninny is generally the man who thinks other men are simpletons. The efficiencies of gas hotplates were low formerly, but, bad as they were, they were superior to the efficiencies obtained on the hotplates of electric cookers. Modern gas hotplates are showing efficiencies that are 40 to 50 p.ct. better than the old ones. Electric hotplates if they show when new about 40 p.ct. efficiency are doing well—for such contrivances, which unfortunately show marked alacrity in departing on their downward career. And talking of efficiencies, it must not be overlooked that in London from 11,000 to 12,000 B.Th.U. can be purchased for a penny from the gas suppliers as against 3420 B.Th.U. from the electricity suppliers—where energy is 1d. per unit, which is not the case generally. More frequent figures are 1½d. and 2d. There are other suggestions as to "imitations" on the part of the gas apparatus makers, which are as unfounded as the rest of the childish assertions to which attention has been drawn.

WORKERS AWAKE!

A CORRESPONDENT has called our attention to an article by Mr. J. L. Garvin in "The Observer" for March 29. It is headed "Sleepers Awake!" Our correspondent thinks it should have been "Workers Awake!" Mr. Garvin points out that the industrial question is our one business of life and death, and that we shall either settle it, or it will settle us. He is of opinion that a movement has begun which will shake us out of our inveterate conservatism and our false composure, and compel all interests, including the Government, to grapple with the national necessity for economic reorganization. The conferences between employers and workers that are now taking place are touched upon, as well as the revelations of the times. The large part that labour plays in the present disastrous conditions of industry, and the part labour will have to take if we are to retrieve our position, are shown; and then there is this paragraph on "Work and Wages" which our correspondent thinks should be published in the "JOURNAL." It emphasizes points which have frequently been made in our editorial columns as to the interdependence of our industries, and as to the imperative necessity of the workers making their contribution to our industrial revival. There will be no substantial revival without. The paragraph reads:

Upon the situation as it stands, the first day of the shipbuilding conference threw some fresh light. It proved that the problem lies as much outside the shipyards as in them. "Shipbuilding," as the Chairman (Mr. John Ball) put it very clearly, "is governed largely by the cost of coal, steel, and engines." The syndicated federations in Germany to-day organize economy upon every link in that chain. There are five main things that we on our side have to face. The first is the basic problem of the price of coal. The second is the want of consolidation in the iron and steel trades. The third is that our "sheltered trades," like transport, building, municipal service, and so forth, are enjoying by comparison a parasitical growth, exempt from foreign competition. They are forcing up costs at the expense of our main productive and competitive employments upon which all the rest will depend in the long run. The fourth factor is that the suicidal rigidity of trades union etiquette in this country, as in no other, makes it impossible for the British employer as a rule to equal his German or American rival in elastic and economical organization. The fifth and gravest point for our industrial democracy is that hours abroad are longer and wages less.

Let us look at what is fundamental in these propositions. We do not believe that international legislation for a long period to come will be able to equalize wages by levelling-up, or hours by levelling-down. It is pretty certain instead that, unless the masses of the British nation make up their minds through and through that they must work harder, the standard of life and average prosperity cannot be raised again. All the professional classes, everywhere in Europe, have to work far harder than they ever did. The working classes will have to do the same if they are to achieve a better future and avoid a worse. Why is this an iron law? Why is there no escape from it? The answer is only too plain. We are doing less business in relation to our needs than ever before, except perhaps during the short severe phases of two or three commercial crises a hundred years ago. Yet we have a larger population. But the average output is not only less per man per day than it was before the war; it is positively less per man per hour. Foreign competition is wider and abler than ever before; and it is increasing.

NORTH BRITISH ASSOCIATION OF GAS MANAGERS.

SPRING MEETING IN EDINBURGH.

THE Spring Meeting of the Association was held last Friday afternoon, in the North British Hotel, Waverley Station, Edinburgh. Mr. JAMES CAMPBELL, of Dunfermline, presided; and he was supported at the luncheon by Lord Provost Sleigh (Edinburgh), Bailie Stewart (Convener of the Edinburgh Corporation Gas Committee), Councillor Gregorson (Sub-Convener of the Edinburgh Corporation Gas Committee), Dr. E. W. Smith (London), Councillor J. M. Smith (Convener of the Dunfermline Corporation Gas Committee), and Messrs. J. W. M'Lusky (Glasgow), J. W. Napier (Alloa), G. Keillor (Greenock), W. M. Mason (London), H. H. Gracie (Edinburgh), and John Wilson (Motherwell and Wishaw). Nearly 200 members and friends were present.

LUNCHEON.

The PRESIDENT, in opening the proceedings, said the meeting had always been a very popular one with members of the North British Association. He supposed that to some extent its informal nature conduced to this popularity. That day, however, they were honoured in having as their guests Lord Provost Sleigh and other influential members of the Edinburgh City Corporation. Lord Provost Sleigh was an exceedingly busy man, and they were gratified that he should find time to join them.

Lord Provost SLEIGH remarked that he was delighted to be one of their guests, and had thoroughly enjoyed their hospitality. His first duty was to extend to all members of the Association a very hearty welcome to Edinburgh. The Corporation were always delighted when such conferences were arranged. He felt that he must congratulate the gas industry, because it had held its own in a magnificent way against a very strong competitor—electricity. He had personally taken a very great interest in gas affairs ever since he saw the light. He wished the Association all success.

Mr. JOHN WILSON (Motherwell and Wishaw), proposing the toast of "The Guests," took occasion, on behalf of the Association, to thank Lord Provost Sleigh for his kind words of welcome. Associated with the toast was the name of Bailie Stewart, the Convener of the Gas Committee in Edinburgh. In mentioning the name of Bailie Stewart, he believed he touched responsive chords in the hearts of all the managers present, because it was well known how earnest and hard-working the Edinburgh Gas Convener was in everything pertaining to the welfare of the gas profession. Wherever there was a meeting connected with the gas undertaking, there they would be sure to find Bailie Stewart.

Bailie STEWART, in the course of a brief acknowledgment, said they in Edinburgh were glad to learn of the progress that was being made by the gas industry throughout the country. As against electricity, there was no doubt that gas was more than holding its own. Year by year the industry was increasing and prospering. From personal experience, he knew the high qualifications that were expected from a gas engineer and manager; and speaking from first-hand knowledge, he was in a position to say that the work of management was splendidly carried out all over the country. His best wish for the industry was that it would continue to grow and prosper, and that the present-day members of the Association would continue to carry on the good work that had been satisfactorily performed by their predecessors.

The PRESIDENT reminded them that they had with them Councillor Smith, of Dunfermline, who, on behalf of that city, was, he believed, to deliver a message that would prove most acceptable to the members.

Councillor SMITH said it gave him great pleasure to be with them, as a representative of the Dunfermline Corporation and the gasworks of that city. It was with great satisfaction that the Town Council of Dunfermline learned that Mr. James Campbell, their Gas Manager, had been appointed President of the Association for the present year. Of Mr. Campbell he could say that he would make a good President. Whatever work he took in hand was certain to be carried out well. He believed it was the custom of the Association to hold the September meeting in the town in which the President for the year was professionally engaged. When that point was brought before the Town Council, they unanimously agreed to ask the Association to hold the autumn meeting this year in Dunfermline; and he extended a most hearty invitation to the members to do so. He could assure them that the members of the Town Council would do what they could to make the visit interesting, enjoyable, and memorable.

The PRESIDENT said they would gladly accept the invitation to hold the September meeting in Dunfermline. Speaking for himself, he was highly gratified by the enthusiastic way in which the Gas Committee and the Town Council as a body had taken up this invitation.

Dr. E. W. SMITH (London), submitting the toast of "The North British Association of Gas Managers," asked if there was any reason why the gas industry, with all its status, power, and ramifications, did not have more influence than it had in quarters that counted in London and throughout the country. To his mind, the gas industry was one of the finest commercial organizations to be found anywhere for propounding what it could do. In spite of this, however, the industry did not seem to be very effective in creating an atmosphere which would make people say "Let us have gas;" whereas they were saying, without having any idea of what it meant, "Let us have electricity." This was a state of affairs that had to be put right. This could best be done if everyone associated with the industry would proclaim its virtues. In the gas industry they had something which would stand on its own feet without having to run-down any rival or competitor. The present gas industry was infinitely better than the gas industry of fifty years ago. As a matter of fact, they were only now beginning to realize the possibilities. They had heard from Mr. Lloyd George—and others who knew as much about the subject as he did—that electricity was the solution of all fuel problems. On this point, his personal view was that there were no men in this country—quite apart altogether from their practical knowledge—who were in a better position to get-down to the fuel problem, and to make practical suggestions as to the methods of handling fuel, than those associated with the British gas industry. Why were they not doing it? It was not sufficient to say, "Use gas, and do not use electricity." They had to get-down to a co-ordinated scheme which would include gas and electricity, and which would embrace fuel-oil and coke-oven practice. They must show that, by the co-ordination of all these things, it was possible to produce power and heat at a very much lower price than the cost to-day. They must strive to show that it was the unnecessary competition between all these things which increased the costs of power and heat. At the moment the Leeds University were turning-out some extraordinarily good men—men who would make their mark in the future, and some of whom were already making their mark, in the various undertakings with which they were associated. They wanted, however, more and more to get scientifically-trained business men in charge of their larger gas undertakings—men capable of taking broad views, and who could handle things in a scientific and business-like manner. If it was not possible by atmospheric means to produce ammonia in a big way, then it could not be produced by any method as cheaply as by the gas industry. They must stress points like this all the time.

COKE POLICY.

In this connection, he might ask Mr. Mason what was proposed to be done at Wembley this year in the matter of the display of coke. On the subject of coke, he personally had very strong feelings. Indeed, he felt it was true to say that coke was a neglected bye-product of the industry; and that, too, in spite of the fact that it was in reality its biggest asset. It could be made a very much bigger asset still. Recently it had been effectively demonstrated in many ways that properly-prepared—graded and reasonably dry—coke could be used for domestic purposes; and it was being employed very largely for these purposes, both in the Midlands and in the South. He was quite satisfied that there was not a gas undertaking in the country, with coke available for sale, where it would not pay to give this matter of its preparation and exploitation the fullest possible attention. If managers would undertake to grade the coke and keep it reasonably free from moisture, there would be absolutely no difficulty at all in getting rid of supplies. Indeed, on this aspect of the question, he was personally prepared to guarantee that, in any particular district—given always, of course, proper plant—it was possible to ensure a complete sale of all the coke for domestic purposes. There was no difficulty about that at all, if the subject were tackled in the right way.

The PRESIDENT, with whose name the toast was coupled, remarked that there was reason for congratulation in the progress made by the industry during recent years. There was much useful work for the Association to do.

THE WEMBLEY GAS EXHIBIT.

The PRESIDENT said that at this stage he might call on Mr. W. M. Mason, of the "B.C.G.A.," to report progress in connection with the Wembley Gas Exhibit.

Mr. MASON, at the outset, expressed thanks on behalf of the Wembley Gas Exhibit Executive for being afforded this opportunity of telling the members what it was proposed to do in regard to the present year's exhibition. He went on to explain that the decision that the gas industry should be adequately represented at Wembley in 1925 was come to after most careful consideration by a representative meeting, when it was felt that every opportunity—both by striking display and wide-spread advertising—should be taken to demonstrate to the public the universality of gas as a fuel for domestic and business purposes. Growing competition—supported, unfortunately, by not very carefully thought-out political backing—was trying to make the public think that gas was a thing of the past. The Wembley Exhibit last year, and the splendid Press publicity which it secured—and which it was hoped would be repeated this year—did a great deal to prove that the gas industry was very much alive. That the decision of the leaders to go on with a National Exhibit this year was wise, was proved by the fine financial support to the scheme which had been forthcoming. Scotland, as usual, was not behind. The subscription list included, to date, the following contributions, as well as many smaller ones. Indeed, some of the small undertakings had actually sent in subscriptions of double the amount asked:

	£		£
Glasgow	1410	Greenock	50
Edinburgh	262	Alloa	25
Aberdeen	50	Falkirk	25
Dundee	50	Dunfermline	25

Among the smaller undertakings, he was delighted to report

that Callander, Burntisland, Kilbarchan, and Stranraer were "doing their bit" in regard to the exhibit; while burghs like Airdrie, Dumbarton, Greenock, Kirkcaldy, and Hamilton had either already contributed or were about to contribute their share of the expense. Something had been said by Dr. Smith relative to the display of coke at Wembley this year. At the moment, he (Mr. Mason) could not enter into the details of that; but he could assure them that there was to be a substantial exhibit of coke. The uses of coke from the industrial and domestic points of view would be fully demonstrated.

MAINTENANCE OF DOMESTIC CONSUMERS' APPLIANCES AND FITTINGS—ADMINISTRATIVE POLICY OF GAS UNDERTAKINGS.

By J. W. Napier, of Alloa.

The past five years have witnessed successful efforts towards co-ordination of the affairs of the gas industry—the legislative and administrative side, for which the National Gas Council stands; the advertising of the merits of gas, for which the British Commercial Gas Association exists. Unity is the aggregate value of the individual effort in reaching a common objective. Individualism provides the initiative; but in an industry serving the nation upon a higher basis of economics of fuel supply and industrial products, organized effort is necessary. In this regard not only is advancement sought for, but protection also—advancement in creating a better public service for the users of gas; protection of the interests of gas undertakings, interests that are unselfish and are of communal value and national necessity. Consumpt of gas is an important factor in costs of manufacture and distribution. The continuity and progress of the gas industry is at the consuming end of the business. It is highly essential, therefore, with this clear outlook, to embrace a commercial policy securing business by good maintenance of consumers' appliances.

Having this outlook before us—namely, organized administrative policy—it appears to me that this Association, representative of the gas industry in Scotland, should determine a plan of gas distribution practice for the acceptance of individual corporation and company owned gas undertakings. The Association have the power of influencing the administrative affairs of gas supply, and of directing a new policy. There are problems that are the better for slow growth, before being put into general practice. Maintenance of consumers' appliances is now ready for general adoption. Hitherto, discussion of the duty of maintenance has circled largely round lighting appliances, and consideration has been given to the preserving of the lighting load. It is intended in this short communication to include the whole service of domestic gas supply, to consider the subject in its entirety, and to state conclusions setting forth a definite policy.

Service Pipes.

In the course of my relations with a large number of undertakings throughout the country, I have observed wide differences in practice. There is the case where the proprietor is required to provide and lay the entire length of pipe, the gas undertaking simply providing the street main; and the more common example of the gas undertaking meeting the cost up to the line of street, the proprietor paying for the pipe laid in private ground. There are cases where the gas undertaking provides the entire length of pipe up to, and including the fixing of, the meter, and instances where the cost of piping in private ground is divided between the parties. To apply a rule of strict obligation and equity among consumers, the policy of the cost of pipe from the street main to the line of private ground being met by the gas undertaking, and all pipe laid in private ground being paid for by the proprietor, is justified, and may be held as good practice. Capital cost, and not maintenance, is here concerned. There is a distinct feature in continuing with the proprietors of buildings the duty of first cost. It preserves equity. In similar circumstances all parties are treated alike. With the completion of the service pipe, the responsibility of the proprietor may be said to cease; that of the gas supply authority acting in the interests of consumers begins.

After considerable experience, and, in particular, after making observation of the results of divided responsibility, my settled opinion is that, immediately the service pipe has been completed up to the meter, the gas undertaking should take it over, and accept for the future full maintenance, including replacement when required. The added cost, one year with another, as and when repairs and renewals occur, will not in my view be considerable. Against the added cost, the gas supply authority has single ownership over the entire service pipe. Dual control and responsibility cease. That there should be dual ownership stultifies the position of the supplier of gas in the endeavour to give satisfaction. It acts and re-acts as between the mutual interests of gas supplier and user. The inadequacy of a large proportion of service pipes in almost every gas supply area is undoubted; that this must be so is evidenced in the maximum demand of to-day for cooking and heating compared with the maximum demand of a lighting load only, for which many service pipes now in use were originally laid.

The question will naturally be asked, What of the many service pipes existing under the old policy? The answer is clearly that they be taken over and cared for in the same way. Owners of property are not likely to entertain objections. The gas authority has obtained complete control, and is therefore in a position to preserve aright the pressure and volume of gas up to the meter. This is one of the objectives, and the policy is commended to the gas industry for its intrinsic merits and values. It should be stated that, under the system now projected, the specification of quality and size of service pipe for all new properties will be entirely under the direction of the gas supply authority. Let me say, finally, in regard to administrative duty, that there is no obstacle in the way of municipalities working under the Burghs Gas Supply (Scotland) Act, 1876, adopting complete control of service pipes. In the case of undertakings having special Acts, there may be lack of direct or implied authority; but this is a matter easily remedied. With private company undertakings, no difficulty whatever exists.

Cooking and Heating.

Dealing with piping for cooking and heating appliances comprising fires, geysers, wash-boilers, &c., the tendency is that the gas undertaking carries out the work free of cost to the consumer. In these instances, maintenance is accepted, and no difficulty arises. In cases where the consumer is charged in whole or in part for the fitting-up of cooking and heating appliances, it is suggested that control of the piping for maintenance should be accepted. This should be an easily accepted responsibility, as the fitting-up of installations, if not actually carried out by the gas department, is usually directed by its officials. When the practice obtains of leaving the fitting-up of apparatus to consumers, there is uncertainty as to proper size of piping to be employed. Such practice spoils control, and maintenance is made more difficult. It is as much the duty of the gas department to ensure proper size of piping as to sell or hire-out efficient apparatus. Where this policy of non-control is allowed to continue over the years, there is a multiplying of inconvenience and dissatisfaction of consumers.

The justification of a gas undertaking expending money on piping inside private houses is naturally a subject requiring consideration. The evidences in favour are that, in doing so, additional use of gas is obtained for expenditure already incurred for the service pipe and meter; the piping, being determined by the gas supplier, is adequate; and there is good workmanship. As a result, maintenance is accepted. In addition, where fixing free has been the practice, results have shown that a greater number of consumers take advantage, and therefore a larger volume of business is done. Part of the expense of fixing in cases where appliances are sold outright to consumers can be met by a percentage amount being added to the net cost of the appliance. The opinion is freely stated by officials that asking consumers to pay for fixing in many instances retards progress in the use of gas for cooking and heating. The experience of the writer, looking back over a considerable number of years, in fixing all gas apparatus free, is that there is no desire to depart from the practice. The result has shown a high aggregate consumpt of gas per household per annum, and a price of gas to-day of 2s. 6½d. per 1000 c.ft.—*i.e.*, the rate of 3s. 2½d. *less* 7d. for electricity deficit. There will be many differing characteristics with the many gas authorities, but the policy of free fixing completes at once the control and maintenance of piping in consumers' houses in the supply of gas for cooking and heating requirements.

The absolute need of maintenance of cooking apparatus and of gas fires and other domestic appliances need not be elaborated. There must always be in front of us the fact that gas, by simple reason of its not being a single element of heat, but a mechanical compound of gases, demands in its consumption regulation of supply and inspection and cleaning of apparatus. Maintenance includes free inspection and regulation—replacement parts being charged in accordance with the policy of the undertaking concerned. There should be no distinction whether the apparatus is private property or on hire. In cases where cookers, for example, are supplied free or on hire-purchase terms, the cost of replacement lies, of course, with the gas department.

What difficulties, practical and financial, are in the way, preventing or retarding the maintenance of consumers' fittings and burners? There are none. There are occasions when it is best to free oneself of difficulties by not observing them. It is unnecessary to repeat the evidences in favour of maintenance. A new general policy should be accepted by the gas undertakings in Scotland, to be put into practice within the next twelve months. The best protection for the lighting load is a policy of maintenance.

A constructive policy requires to be defined. The gas undertaking will undertake the work of maintenance of consumers' lighting appliances. The technical knowledge and experience of the gas supplier enable the work to be done in the most satisfactory manner. The education of the gasfitter is a permanent institution of the gas industry, and he is now a technical expert. The gas department may seek the assistance of local gas-

fitters, but this is a policy for each undertaking to decide for itself. The organization of the work must originate in the gas department. A definition of maintenance is required. The appliances to be maintained are those in use, whether privately owned or the property of the gas department. Consumers should be advised as to discarding out-of-date and inefficient burners. They should be supplied with suitable burners, &c., at charges to be determined by each undertaking. Only the actual material supplied should be charged. The scheme should embody free inspection and cleaning. Each undertaking should select, and control the supply of, burners of recognized merit. This requires combination with local plumbers and gasfitters.

As regards the payment of maintenance service, there is only the one source—namely, the price of gas. Arising out of the trend of opinion expressed in this paper is the matter of equity as affecting the various classes of consumer. In all business legitimate expenditure is placed on the cost of the article supplied. Allocation of value to consumers is determined by a differential scale of charges. This refers more especially to large industrial users who benefit by low rates on the basis of quantity used. Large users of gas for domestic purposes can be given a scale of discounts.

My endeavour has been to stimulate an interest in the subject of maintenance, in order to hasten the general adoption of a policy. Time was when a low price of gas was the one end and aim in selling gas. Price alone, with the present-day mentality of the public, is no longer the substantial deciding factor it used to be. To-day the position is altered, and service is an essential duty. It is hoped that unanimity will prevail on this subject. It will be understood that I have left to Mr. M'Lusky the question of costs of service.

MAINTENANCE OF CONSUMERS' APPLIANCES.

By George Keillor, of Greenock.

A study of the history of gas supply in Scotland teaches us that the maintenance of consumers' gas appliances is not a new question. Forty years ago (to go no further back) the question was under discussion; and in certain enlightened quarters it had, even then, become the custom not only to give away flat-flame burners, but to clean bracket taps and swivel joints, and do other odd jobs without charging the customer anything for the work.

Thirty-three years ago a paper was submitted to this Association by my father, entitled "How to Keep Down Complaints and Grumbling among Gas Consumers." The following quotations are taken from this:

"Let your meter inspector be a man of sound mind and judgment, thoroughly trained in the distribution of gas, and able to discuss with customers *on the spot*, in a courteous manner, everything connected with gas supply, to hear their complaints quietly, say nothing but what is absolutely necessary, and certainly never show the least ruffle of temper or any unnecessary independence; after which make it a point to quieten the grumbler by, if possible, removing the cause of his discontent. . . . I have come to the conclusion that the real and only cure for this epidemic of grumbling is that the meter inspector must deal with all complaints on the spot; but whatever means may be taken, or at whose expense, nothing must be left undone that, in reason, will satisfy the consumer. And whatever or by whom it may be done, let it be superintended by the gas official; for who has greater interest in the gas that is being sold than the man who makes it? And is it not obviously for the benefit of all gas companies and corporations to keep in their own hands, if not the whole control of all internal fittings, at least the entire superintendence of the alterations and improvements in gas lighting when opportunities occur? . . . I hold that every manager should provide his officials with a stock of new burners of all sizes, to be given to all and sundry. And all who occupy the office of meter inspector and collector—who may be the manager himself in small gas-works—should be men thoroughly practical, and not only able to discuss the different systems of gas lighting with consumers, but also be of a straightforward and courteous disposition, with a strong aptitude to do good business in a real business fashion. . . . I say: Please consumers, and do good business with them; and you cannot fail to satisfy your directors. . . . In the age we live in, the gas man's independence is not how much superiority he can show over others, but only the independence gained by being able to satisfy the consumer with his goods. . . . It may be asked, 'How can a meter inspector have time to deal with such matters when on his inspection, and how is it possible to satisfy every person?' In this question lies the whole problem. But it is a problem, I am convinced, it will pay to solve, and one which after all is not very difficult of solution. It would no doubt add a few days, or even a week, to the time in making the survey; but is it not a fact that this man is, by the aid of the meter, selling our stock? . . . Competition in lighting is increasing, as in everything else; and to please our customers, our representatives must be courteous, long-suffering, patient, and practical."

About 32 years later we find Mr. Arthur Coe, in his interesting book "The Scientific Promotion of Gas Sales," giving publicity to similar sentiments, and pointing out that the value of the meter inspector had too long been under-estimated.

The idea of the principle of maintenance and salesmanship was born in those distant days, and the various statements submitted this afternoon bring the subject up to date. They indicate very clearly the advance we have made in principle and opinion, and also in the actual practice of organized maintenance. The evolution of the idea has been slow; but now that a practical solution has been found and described, it ought to be adopted immediately and universally.

In my opinion the present-day solution of the problem lies in the regular free overhaul of all gas-consuming appliances. But at the same time we should use our utmost endeavour to promote and retain the goodwill of every citizen. It should also be our endeavour to seek out and multiply points of contact between our servants and the public. An organized system of public service, humanely designed and administered, does this; and if we consider it to be our duty to guide and instruct consumers in the safe and economic use of gas, the road to success will be all the easier. The Gas Regulation Act, in fixing the responsibility for the adjustment of consumers' appliances as required for the efficient use of the quality of gas to be supplied, gives power to the industry and an impetus to the movement in favour of general maintenance.

The particular incidents which led to the adoption of an organized system of maintenance in Greenock need not be related. It is sufficient to say that fully three years ago a careful investigation proved (even to us) that the system in vogue—and it was considered a well-ordered one—did not fit in with modern requirements. Under the old system our public-service relations were fortunately above the average. We did a lot of free maintenance work, and encouraged our customers to think well of us in other ways, but points of public contact were few and far between and limited only to the "perky" counting-house clerk, the hustling, uninterested meter reader, and the soulless, untidy, tobacco-smelling gasfitter and pipe-layer. It was also known that our rivals made a door-to-door canvass of the district; and as they were none too particular as to the accuracy of the facts and figures they supplied to gullible householders, it was incumbent upon us, as business people, to follow them up and tell the people the truth.

Nowadays new customers are difficult to get; and it is easy to lose old ones. If old customers are dissatisfied with the service we give them, it is unlikely they will contemplate an extension of that service. If, therefore, we are to have repeat orders and additional sales of apparatus, it is obviously incumbent upon us to give absolute satisfaction with existing services. Having regard, therefore, to all the circumstances, and realizing that the systematic and regular free overhaul of consumers' appliances is *the* means of retaining custom and goodwill, and also the preparatory step to raising the standard of efficiency in the use of gas and the development of sales, I at once decided in favour of an organized system of maintenance. In a very short time the new system proved to be of inestimable value as a business and goodwill getter. In the free maintenance of consumers' fittings you have an Aladdin's lamp which, if properly used and exploited, will bring you much prosperity.

Hitherto, with no organized system of inspection, and having no regular and sympathetic contact with the public—contact which well-trained, intelligent, smart young inspectors and salesmen now provide—we were losing ground to our "slick" competitors. Now, however, with an organized system, it is the other way round; instead of losing customers we retain them and recover old custom as well.

I have given this subject a good deal of thought; and knowing, I hope, the needs of the industry, and how intense electrical competition has become, the sooner every gas undertaking—large or small—has an organized system of inspection in operation, the better it will be for all concerned.

Might I suggest that, though almost any system of maintenance is better than none, it is a mistake to superimpose a real live modern maintenance system upon an old-fashioned public service edifice. Therefore "plan before you act, and look ahead before you step." Before launching your system set up a real standard specification for services and for the canvassing of houses; see that the existing gasfitting and pipe-laying organization leaves nothing to be desired; be sure that the method of receiving and dealing promptly with complaints and new orders is foolproof; decide to sell at fair working profit only the best appliances, and make a suitable arrangement with plumbers, gasfitters, and ironmongers, so that they also may sell only the best, indeed what you recommend; encourage local traders to work with you, not against you; encourage them to look upon your showroom as their showroom, and try to make their shop windows your district showrooms, even if you give them a cheap supply of gas for window displays. Other points might be mentioned, but they are obvious even to the uninitiated.

With regard to showrooms, it is of the utmost importance that they be kept scrupulously clean, and representative of a real live service. Frequent changes in display are a necessity, otherwise a showroom loses its gripping power, and becomes lifeless. If advertising is indulged in, it should be judicious,

non-controversial, and truthful. Might I here utter a word of warning to the many small and medium-sized gas undertakings who are rapidly coming within the ambit of the linked-up electricity undertakings? Most of them are doing nothing to ward-off the advance upon their territory; and I am afraid that, unless managers are encouraged to proceed with works improvements and to engage in district propaganda, directors of companies and local authorities will have themselves to blame if business losses lessen profits. Incidentally, disgruntled gas consumers in badly-served districts do a tremendous amount of harm to the gas industry generally, and retard real co-operative advancement. Remember, "He profits most who serves best."

Particulars of our simple free maintenance scheme were recently given in a paper to the Scottish Salesmen's Circle by my Chief Assistant, and fully published in the "Gas Salesman" for Jan. 28.

All our public service employees, including maintenance men, meter readers, inspectors, gasfitters, foremen, showroom attendants, and the staff generally, work shoulder to shoulder. All our men are naturally enthusiastic, and I personally try to share the burdens of the men on the firing line: "It's dogged as does it; and nothing succeeds like success."

Our industry is of great national importance, despite the forgetfulness of the politician. Its manufactures are unexampled. Gas is an indispensable article of commerce. It is the cheapest form in which light, heat, and power are obtainable. Coal conservation, the achievement of a smokeless atmosphere, and better health for all are the aims of the gas industry, and all its actions from the scientific carbonization of coal to the promotion of gas sales and the teaching of the public in the efficient use of the gas consumed are actuated by these aims. This is surely something to boast about in these highly scientific, highly competitive times; and if we are to be true to our heritage and retain our place in the sun, surely something more is required of us to-day than a continuance of the talk which has been going on for thirty or forty years. Now we have all got to act; and I sincerely hope that this meeting will resolve unanimously in favour of the immediate adoption of free maintenance.

A contribution by Mr. J. W. M'Lusky, of Glasgow, together with the general discussion, will be published next week.

INSTITUTION OF ENGINEERS-IN-CHARGE.

Twenty-Fifth Annual Dinner.

That the Institution of Engineers-in-Charge, who were incorporated in 1923, are in an exceedingly flourishing condition was manifested by the crowded attendance at the twenty-fifth annual dinner—which took place last Saturday evening, in the Venetian Chamber of the Holborn Restaurant. Members are, of course, not everything in an organization of this character; but no one who was privileged to attend the function could doubt that the enthusiasm which is also necessary is present among the members in abundance.

The chair was occupied by Mr. T. Cooper, M.A.(Cantab.), M.Inst.C.E., M.Inst.Mech.E., M.Inst.E.E. (Engineer-in-Chief to the Metropolitan Asylums Board), the President of the Institution; the Vice-Chairman being Mr. C. A. Pickles, who is Chairman of the Institution. There were a large number of guests, the acceptances including Col. Sir Arthur Holbrook, K.B.E., M.P.; Mr. W. H. Patchell, M.Inst.C.E., M.Inst.Mech.E., M.Inst.E.E., Past-President of the Institution of Mechanical Engineers; Captain H. Riall Sankey, C.B., C.B.E., M.Inst.C.E., R.E. (Ret.), Past-President of the Institution of Mechanical Engineers; Mr. E. A. Sandford Fawcett, C.B., M.Inst.C.E., Chief Engineering Inspector to the Ministry of Health; Dr. Alex. Russell, M.A., LL.D., F.R.S., M.Inst.E.E., President of the Institution of Junior Engineers; Dr. W. R. Ormandy, F.I.C., F.C.S., President of the Institution of Automobile Engineers; Brigadier-General Magnus Mowat, C.B.E., M.Inst.Mech.E., Secretary to the Institution of Mechanical Engineers; Mr. Alcwyn A. Jones, President of the Institution of Heating and Ventilating Engineers; Mr. Leon Gaster, M.Inst.E.E., Secretary to the Illuminating Engineering Society; Mr. G. Stevenson Taylor, O.B.E., H.M. Senior Engineering Inspector of Factories.

Science and Industry.

Following upon the Loyal Toasts, Mr. W. H. Patchell submitted "Science and Industry." Science and industry were, he said, very close together, and he thought it was impossible for them to be too close together. Could one, indeed, tell where the one ended and the other began? It would be very difficult. Personally he would have worded the toast "Industry and Peace." Peace was the more urgent thing for them at this time, because without peace among themselves they could not use their industry, and they could not use their science. So industry and peace were now what they were all striving for, and both were absolutely essential to them.

Dr. W. R. Ormandy, in reply, remarked that there was no doubt that this country, since the war, had not maintained that regard for science which made itself so evident when the Government discovered that they could not do without the scientist and the engineer. During his own visits to the Continent he had seen some most astonishing things, one or two of which he would like to mention. It was really remarkable to see what was going on around them. The members might have heard that methyl-alcohol was used very largely in the manufacture of dyes and disinfectants. Well, this country was dependent upon the wood distillers of America for its supplies. But the Germans had discovered, after ten or twelve years' work, that, by passing water gas over a catalyst at a high temperature and high pressure, they could make methyl-alcohol, and of this they were at the present time producing some 6000 tons a year. This country was buying from America at £50 or more per ton what Germany was thus turning-out at a cost of about £12 a ton. But in this country did one think it was possible to get manufacturers to spend tens of thousands of pounds a year merely because their technical advisers had told them there were difficulties which could be overcome? In Germany, they had realized that science paid, and was an asset to a country.

Converting Coal into Oil.

They had also succeeded in Germany in converting coal into oil—not distilling the coal, but charging it into a retort under pressure and heating in the presence of hydrogen, so converting a large proportion of the coal into oil. This did not yet appear to be a commercial proposition; but they were dealing with half-a-ton an hour, and in his opinion the technical difficulties which still remained would be solved. When this happened, it would alter the whole economic position of the world. By means of coal, countries would come into their own again; and the British Empire, possessing coal deposits in practically every Colony, would be in a position which to-day it unfortunately did not occupy. There was no doubt about it that petrol and heavy oils were the fuels of the future. More than one European Government were taking a practical interest in the question; and the Fuel Research Board of this country were by no means behind their Continental neighbours in the attention they had given to this important development. In connection with various matters, marvellous progress was being made every day. "We in this country," concluded Dr. Ormandy, "have no reason to hide our heads. Where we have failed is that we have left it to Germany to develop our discoveries into commercial propositions. Science pays, and science is industry; they are one and indissoluble."

Col. Sir Arthur Holbrook, proposing "The Institution," recalled the fact that on a similar occasion a year ago the principal speaker had urged upon them all the great importance of research. The truth of what was then said had been amply borne out by Dr. Ormandy. There was no doubt in his own mind that, if the English people made up their minds to it, they could lead the whole world. They must wake up to the fact that engineering in this country had reached a position which called for very serious thought. Workmen must give a full output for the wages they received, and this could only be achieved by the establishment of peace in industry. Surely the time had arrived when they should all be settling-down to see what could be done to restore this country's position as a great commercial power. He agreed that those who were leaders had given insufficient attention to scientific research; and this must be changed. But the great aim of all of them for the time being should be to try to get a better understanding between masters and men—to endeavour to restore confidence. The growing class feeling must be broken-down. The Institution could do a great deal to bring about that good feeling which was so greatly to be desired.

Responding, the President pointed out how greatly the status of the engineer-in-charge had improved during the last quarter-of-a-century. At the present day greater economy and increased efficiency were absolutely essential; and the best results could only be obtained by the exercise of the skill of the engineer-in-charge.

"Our Guests and Friends" was submitted by Mr. W. R. Welton (the Chairman of the Technics Committee), and responded to by Mr. H. G. Burford, who urged the need for closer co-operation between the Institution and the senior organizations of the country. "The President" was toasted, and in reply Mr. Cooper acknowledged the zealous service rendered to the Institution by Captain Alfred E. Penn, the indefatigable Hon. Secretary.

Smoke Abatement.

At a sessional meeting of the Royal Sanitary Institute recently held at Leicester, Mr. F. G. M'Hugh, Chief Sanitary Inspector at Leicester, read a paper on "Smoke Abatement." In this he emphasizes that domestic smoke presents the greatest problem; and he goes on to say that there are three remedies—gas, electricity, and smokeless solid fuel. Electricity for heating can be dismissed, on account of expense. Gas also is expensive for the poorer classes. He mentions the interesting decision of the Hull Corporation to instal central heating in 600 concrete houses about to be built. In the Austin Motor Company's village at Northfield, near Birmingham, each house has its central heating system, which is coke fired. These dwellings are smokeless, popular with the tenants, economical in fuel, and well ventilated. Cooking is done by gas. It is the opinion of Mr. M'Hugh that the solution of the domestic smoke problem lies in low-temperature carbonization. In this connection he refers to the Nottingham scheme: "The manufacturers of Coalite have entered into a contract with the Nottingham Corporation, who have undertaken to purchase a minimum of 2 million c.ft. of gas per day for a long period. A further contract has been entered into with a colliery company for coal for 25 years. The plant, it is stated, will be capable of dealing with 1000 tons of coal per day. I am given to understand that this scheme is receiving Government support."

NEW GAS-WORKS AT PITWINES, POOLE.

[Extracts from a Supplement to the Presidential Address of Mr. P. G. G. Moon, F.C.S., to the Southern Association of Gas Engineers and Managers.]

The gas requirements of the Bournemouth Gas and Water Company's district have, in the past twenty years, practically doubled in each decade. The popularity of the 25 miles of coast land administered by the Company, and the continuous estate development that is taking place throughout its length, suggest that this tendency will persist for a considerable time to come. It became obvious a few years ago that, having regard to the congested state of the existing works of the Company at Poole, it would be necessary in the very near future to construct new works to meet the continually growing demand.

Two courses were open to the Company. One was to acquire land adjoining the existing works on Poole Quay; but as this would have involved the compulsory acquisition and demolition of some seventy cottages and a large pottery works, as well as leaving the extended works closely surrounded by houses, it was turned-down. The second was to obtain full parliamentary powers over the Pitwines site, situated some 500 yards inland from the Poole Quay Works, and on which the Company already had purifiers and a 2¾ million c.ft. gasholder. The chief disadvantages of the site were: First, that it was reclaimed harbour mudlands, with very poor subsoil for foundations; and, secondly, that there was no direct access to a deep-water berth on the harbour. After careful consideration, it was decided to extend on this site, and to overcome the lack of deep-water accommodation by connecting-up the existing coal unloading transporters at Poole to the new site by means of an overhead cable conveyor. The necessary powers were obtained in 1919, and designs for the new works were started in 1923.

GENERAL VIEW OF WORKS FROM THE AIR—OCTOBER, 1924.

Note the special reclamation for the Coal Store.

General Scope of the Works.

After a careful study of the whole position, it was decided to lay out the works to have an ultimate capacity of three sections of 4½ million c.ft. per day each, or 13½ million c.ft. per day in all. Having regard to the difficulty and risk of putting in foundations at a later date in such difficult ground alongside existing buildings, and having in mind the normal rate of increase at Bournemouth, it was decided to put in such buildings as the main block (housing the water gas plant, boilers, producers, exhausters, and electric generators), the coal store, and sulphate house of sufficient size to deal with the whole of the three sections.

It was estimated that the first section would provide adequate capacity for four to five years from 1925 onwards.

Foundations.

A large number of borings were made and carefully plotted. Below the reclaiming material, which consists of some 3 ft. 6 in. to 10 ft. of clinker, lies a layer of harbour mud of thickness varying from 1 ft. 6 in. to 8 ft. Under this there is a bed of clay of circumscribed area and varying thickness, all of it well below tide level. Beyond the confines of the clay there is nothing but a great depth of fine waterlogged sand. The whole area is full of tidal water; and the sand is at such a depth, and so fine, that the extensive pumping which would be necessary would be both costly and full of difficulty and danger. Altogether some 74 borings were made.

It was found that there was room on the thicker portion of the clay bed for the retort house and the relief holder, but that all the rest of the plant would have to depend either on reinforced rafts below the mud level or upon reinforced concrete piles. Careful estimates were made of the comparative costs of these two methods, with the result that it was found that, although expensive, the piling method was cheaper than the raft method, largely because of the considerable excavations that would be necessary in the latter case to get below the mud level, and the large amount of timbering and pumping that would be required.

Experiments were made with 14 in. square reinforced piles, and it was found that a good "set" could be obtained at an average depth of from 25 to 30 ft. The piling method was finally adopted, and the variations in the ground resistance as the work proceeded fully confirmed the wisdom of this decision. In many cases the piles would penetrate fully 8 ft. practically by their own weight. Some piles would reach their "final set" with the head of the pile 1 ft. below ground level, while piles of the same length (30 ft.) right alongside would finish 8 ft. out of the ground. The set specified was "that when using a 30 cwt. ram with a fall of 4 ft. 6 in., the piles should not have a set of more than half-an-inch after ten blows." The piles, after driving, were cut-off to the various required levels, capped, and braced or covered with reinforced concrete rafts, as circumstances required.

The carrying capacity of the 14 in. square piles has been taken throughout the job at 50 tons per pile, with a factor of safety of six. After some preliminary experiments, the Birmingham Concrete Steel Company, who were responsible for the reinforced concrete design throughout the works, submitted data which justified the adoption of 50 tons per pile as the safe carrying-load for the conditions obtaining at Pitwines.

Some interesting facts were noted during the pile driving:

(*a*) Owing to the mud layer and the superincumbent reclaiming material, considerable vibration was set-up during driving in a large area of the surrounding land. The vibration was so considerable that it was obvious there would be considerable risk if driving were done alongside existing buildings.

(*b*) The piles passed through the tough clay bed, where it was encountered, with comparatively small resistance, and only on reaching the fine sand below was real resistance found.

(*c*) Two piles driven alongside the retort house foundations, which were in the form of reinforced concrete slabs carried on the clay, and not on piles, lifted the nearest loaded retort house foundation 2 in., and cracked the re-

GENERAL VIEW OF WORKS — MARCH, 1925.

inforced beam of which the foundation was formed. The displacement effect of the piles must have acted on the clay as on a fluid, and pushed up a wave of clay, which gave an upward thrust of sufficient intensity to lift and crack the loaded foundation slab.

General Arrangement.

Broadly the works are set-out in relation to two base lines—one through the main block of buildings parallel to the railway, and the other at right angles thereto for the retort houses.

Cableway Conveyor.

The cableway conveyor is the connecting-link between the existing Poole Works at the quayside and the new works at Pitwines. It is designed for an ultimate capacity of 100 tons of coal per hour, although it will at first function at 50 tons per hour. It is of the double cable type—one cable being fixed and supporting the loaded buckets which run on it, and the other moving and acting as the hauling cable. The total power required when the cableway is called upon to take 100 tons per hour will be 15 H.P. One man only is required to operate it. He works at the loading end; the tipping being done automatically. The automatic self-tipping buckets take 12½ cwt. of coal each, and "shot-pouch" filling arrangements prevent over-filling, and so reduce the risk of dust.

The cableway takes coal, coke, and ashes from Poole to Pitwines, and can, if necessary, take coal from Pitwines and feed it into the retort house conveyors at Poole. Coal can be fed from the steamer, *via* the transporters and the cableway, direct

RETORT HOUSE, SHOWING SKIP HOIST GUIDES.

to the retort house or coal store at Pitwines. The cableway will pass over two public roads, which are protected by reinforced concrete bridges; and here the carrying cables are arranged one above the other.

The cableway conveyor, protection bridges, and loading stations were all constructed by the Mitchell Conveyor and Transporter Company.

Coal Store and Coal Handling Machinery.

The terminal station of the cableway is at one corner of the Pitwines coal store. Here automatic tripping devices are arranged to trip the cable buckets into any one of the three hoppers provided for coal, coke, or ashes respectively. The coke and ashes are picked-up from their hoppers as required by the telpher, which is designed to serve the terminal station at this point. The coal is fed from its hopper on to a reversible rubber belt conveyor 24 in. wide, which runs the whole length of the coal store. From the reversible belt, the coal is taken either direct to the retort house through an automatic Avery weighing machine or on to a travelling belt conveyor 18 in. wide, which can be traversed to any position in the coal store with its throw-off carriage set at any required spot. The throw-off carriage is 26 ft. above ground-level, and the coal store can be filled throughout, without man-handling, to an even height of 20 ft. The travelling conveyor is carried on a steel-framed traversing bridge supported by the two longitudinal walls of the coal store and by a central reinforced concrete gantry down the middle of the store.

The coal is reclaimed when necessary by a travelling level luffing electric crane with a grab of 30 cwt. capacity. The crane is carried on a girder bridge spanning from one wall to the central gantry. The crane jib is long enough to reach from its central position to either side of the coal store, and to deposit the coal either into a feed hopper for the reversible belt conveyor or, when it is desired to send coal from Pitwines to the Poole Works, into a reinforced concrete feed hopper for the cableway conveyor.

The coal store itself is constructed of reinforced concrete, 315 ft. long by 100 ft. wide, with the rail level for the crane and conveyor 20 ft. above ground. A dust and wind screen is carried to 7 ft. above the rails around three sides of the store in thin reinforced concrete. The total capacity of the store is 15,000 tons.

An attempt has been made by a very broad but comparatively inexpensive treatment, to relieve what must otherwise have been, having regard to the over-all dimensions, an unsightly box-like construction, and give it a more pleasing elevation. The effect has been obtained by oversailing 18 in. with the wind and dust screen walls, which are carried on precast corbel blocks, at the same time setting-out the walls at each corner and carrying the apparently massive buttresses so formed above the general level.

Retort House.

The retort house is planned with its main axis at right-angles to the coal store, and in such a position that it can receive coal from the reversible belt conveyor running parallel to the coal store through the Avery automatic weighing machine into an automatic electric skip hoist which will be described later. The retort house is of the Woodall-Duckham vertical type, and has six beds of four 7-ton retorts arranged in two benches. The retorts themselves, with their heating flues, are built-up of silica blocks so designed that the "breathing" due to expansion and contraction can be accommodated without distortion of the retorts or flues.

Two producers are arranged at the end of each bench; and the carbon monoxide flues, secondary air flues, and regenerators are disposed along the longitudinal walls of the retort bench so that they are available for inspection or repair with a minimum of inconvenience. The producers are of the hanging-bar grate type, and special attention is given to the distribution of cooling water for the bars and the sealing of the water plate against short circuiting. The ashes are continuously extracted into a cast-iron hopper of the same type as that used for the coke extraction on the retorts.

The waste gases are passed through a waste-heat boiler having a capacity of 4750 lbs. of water per hour from feed at 60° Fahr. to steam at 120 lbs. per sq. in.

The coke is received into telpher skips of the balanced-wheel type, of sufficient size to take the coke from four dischargers. The skips are then pushed out and lifted by a telpher, which takes them to the coke hoppers or any desired part of the works. The plant for filling the top coal and coke hoppers consists of automatic electric skip hoists and belt conveyors. With the skip in the bottom position, coal is allowed to run from the Avery automatic weigher; and as soon as the weight exceeds an arranged figure, the hoist starts upwards, and the supply of coal is automatically cut off. When it reaches the top, the skip automatically tips and descends. On reaching the bottom position, it opens the coal feed again, and the cycle of operations is repeated.

PILING FOR MAIN BLOCK BUILDING.
Note the difference in the final levels of the various piles.

The coal at the top, when discharged, is fed on to a fixed rubber belt which runs over the hoppers nearly to the middle of the house. From this belt, it falls on to a short reversible rubber belt, which is mounted on an independent framework carried on wheels, which can be traversed so that one or other of its ends is over any hopper (either coal or coke) in the house. It will be seen that by this arrangement coal or coke can be automatically put into any hopper from either the coal hoist at one end of the house or the coke hoist at the other.

The screened coke is fed from the outside concrete coke hoppers into the coke-hoisting skip by a reversible rubber belt conveyor operated electrically from the top of the retort house. The coke skip discharges at the top of the retort house on to a fixed belt conveyor similar to the one at the coal hoist end, and this in turn discharges on to the shuttle belt conveyor.

The skip hoist and belt conveyors were supplied by the Mitchell Conveyor Company, who have many similar installations working in large electricity generating stations.

The retort house is of steel framework, filled with Bridgwater brick panels; and the roof is covered with corrugated iron sheeting, protected by bitumastic covering, and coloured a dark

maroon. The house and bench are built on reinforced concrete rafts carried on a clay bed 13 ft. below ground-level; and, as the latter is 7 ft. O.D., it will be seen that the rafts are well below tide level. The full guaranteed capacity of the house is 2,730,000 c.ft. of gas per day of 480 B.Th.U. The pressure regulation is effected by means of "Arca" regulators.

The present retort house is built at one end of the coal store; and the lay-out of the coal store and works generally is designed to accommodate two or three more retort houses of either vertical or horizontal type, parallel to the first, all capable of being served by the existing coaling plant.

Coke Hoppers and Screening Plant.

The telpher serving the retort house is arranged to pass along the centre line of a set of reinforced concrete coke hoppers. The same telpher and an extension of the coke hoppers on the present line will serve the second retort house when it is erected. An attempt has been made in the design of the hoppers and screening plant to overcome some of the disadvantages of our present methods. The average rotary coke screen is normally fairly long, and has to serve the purpose not only of a screen, but also of a very inefficient conveyor, thus tending to increase the amount of breeze made. In the present design the coke hoppers have been divided into three carefully-proportioned longitudinal partitions; and on the two middle walls a very short rotary screen has been mounted, which can be traversed from end to end of the hoppers. The line of travel is coincident with the telpher centre line; and the hopper on the screen can take a full telpher skip. The screen is of 4 ft. 6 in. in diameter and 11 ft. long, of which only 8 ft. is perforated. It separates the breeze in the first portion and the broken coke in the remaining portion; and the large coke falls out at the end. The whole of the sections are enclosed to reduce dust, and shoots lead the screened products to their appropriate longitudinal hoppers. The breeze, having the steepest angle of repose, falls into the central narrow hopper. With this arrangement not only is the travel in the screen reduced to a minimum, but the falling coke can be largely arranged to fall upon existing coke slopes, and further breakage due to long drops can be avoided.

Condensers.

The condensers are of the Holmes type with horizontal cast-iron tubes arranged with water headers so that the water circulation follows a definite path throughout. They are of 3 million c.ft. capacity, and according to tests made with similar condensers at Poole are more efficient and reliable than any other type. The following figures give some idea of the performance of this type of condenser when dealing with 2½ million c.ft. of gas per day:

Water inlet	58°	Fahr.
Gas outlet	60°	,,
Water outlet	121°	,,
Gas inlet	140°	,,

They have the added advantage that the water tubes are accessible for cleaning purposes without shutting-off the gas stream.

Owing to the peculiar difficulties of the site, the foundations for the condensers for the future No. 2 retort house were put in at the same time as the general foundations for the first section.

Main Block Buildings.

The main block buildings are designed to house ultimately all the water gas plant, boilers, exhausters, and generating plant required for the completed works, as well as the fitting shops and messrooms. They are designed in reinforced concrete carried on reinforced concrete piles; and, as with the coal store, an attempt has been made, by a simple treatment, to give them a reasonably pleasing appearance. The three fuel-using plants—water gas, boilers, and producers—have been arranged adjacent to each other, and the hoppers serving them are on the line of the telpher.

The hoppers are of sufficient capacity to hold three days' fuel, so that no night or week-end work on the telpher is necessary in filling them. Instead of designing these hoppers as a separate structure supported on the roof of the building, they have been incorporated with the whole design, and have thus given a better opportunity for developing the general elevation.

Between the hoppers for the water gas and those for the boilers an ash shaft has been left, with a sunk well, so that a skip just below ground-level is always available to receive ashes from boilers, water gas plant, or producers. These are dealt with by the telpher, which also runs over the ash washing plant.

A deep parapet around the power house roof masks the four cast-iron tanks supplied by Messrs. Mather and Platt: Hard water, 47,000 gallons; soft water, 47,000 gallons; salt water, 27,000 gallons; and weak liquor (covered), 27,000 gallons. When full these tanks represent a load of 800 tons on the roof.

COAL STORE, WITH RETORT HOUSE AND TELPHER IN BACKGROUND.

In the top of the two towers flanking the telpher section are placed two cast-iron tanks of 17,500 gallons capacity each, also by Messrs. Mather and Platt, for high-level water and strong liquor respectively.

Carburetted Water Gas Plant.

The carburetted water gas plant consists of one set of 2 million c.ft. per day capacity by Messrs. Humphreys and Glasgow. The generator is of the self-clinkering type. It is unlined, and jacketted with a water boiler. The bottom of the generator shell ends in a water seal carried in a revolving cast-iron ash pan. The latter carries a conical grate which projects above the water seal and supports the fuel bed. This conical grate is set slightly eccentrically to the generator shell, so that any large clinkers which drop into the annular space between the grate and the shell are crushed as the ash pan revolves. A charger, hydraulically operated, feeds the coke from the hoppers overhead into the generator while the latter is at work. With the self-clinkering grate and the hydraulic charger 24 hours full operating per day is possible. That is to say, with a six-minute cycle, 240 runs in the 24 hours are possible. Automatic chargers are fitted to the four water gas sets in use at the Poole Works. They have been very successful, and have increased the output of the plant by 7 to 10 p.ct. The plant is fitted with a waste-heat boiler of the usual type and the latest design of dust extractor.

Boilers.

Two Stirling water-tube boilers of 10,000 lbs. per hour capacity each are installed, fitted with Babcock and Wilcox chain grate stokers mounted independently on rails, so that they can easily be withdrawn bodily for repairs. These stokers are interchangeable. Continuous carbon-dioxide recorders are connected to each boiler. It has been found that with similar boilers at Poole, also controlled by carbon-dioxide recorders, an evaporation is obtained of 6·8 lbs. of water from and at 212° Fahr. per lb. of coke breeze. The whole of the steam-using apparatus on the works is arranged to exhaust to vacuum, using two 1000 H.P. tubular condensers originally fitted in torpedo-destroyers and bought from a local ship-breaking yard for £250 each, complete with air pumps.

Producer Plant.

Alongside the boiler house are situated the 350 H.P. Dowson suction producers which supply the gas for the gas-engine dynamo plant in the adjoining power house. These are placed in this position not only so that they shall be near the engines and under the hoppers, but also that they may be served by the one stoker, who will be in charge of the boilers, water softening plant, feed pumps, condenser plant, and hopper storage.

Some criticism has been passed on the use of producer gas for power production on a gas-works. In reply to this, it may be pointed out that a "load" of the type found in a gas-works power house, persisting as it does throughout the whole 24 hours, eliminates most of the disadvantages usually, and rightly, associated with such plants working intermittently.

Water Softening Plant.

The water softening plant of the "Permutit" type, installed by United Water Softeners, Ltd., is situated in the producer house. It has a capacity of 48,000 gallons per 24 hours. A similar plant, but of larger capacity, has been in use at the Poole Works for some time past, and has proved itself to be very reliable. Some such plant is particularly desirable for waste-heat and water-tube boilers. Two precautions are necessary, however. One is to "blow down" the boiler at sufficiently frequent intervals; the other is to use Monel metal for the valve seatings and gauge fittings, as brass and gun-metal are attacked by the alkali in solution.

Power and Exhauster House.

The whole of the coal gas and water gas exhausters, electric generating plant, water gas fans, and compressors for the completed works will be housed eventually in the one building. The plant, when finally installed, will be looked after by one charge hand and one assistant per shift.

The exhausters will be of uniform size throughout—viz., 125,000 c.ft. per hour. Three, made by Messrs. G. Waller & Sons, are installed at present. They are situated on an elevated platform, with three lines of easily accessible mains on the inlet and outlet sides respectively. These are so arranged that the gas from any inlet main can be put through any exhauster and into any outlet main. This uniformity of arrangement and interchangeability of exhausters simplifies the problem of stand-by plant, and also reduces the number necessary.

The first two electric generating sets consist of two 150 KW. 230 volts D.C. British Thomson-Houston generators, direct coupled to two 250 H.P. twin cylinder horizontal gas engines. The whole installation of producers, gas engines, dynamo, compressors, and auxiliaries was supplied by the Keighley Gas Engine Company.

In the power house are also situated the two 75 H.P. steam turbine blast fans for the water gas plant. These also run to vacuum, and are connected to the water gas plant by a rectangular reinforced concrete duct of 3 ft. 6 in. by 2 ft. section, instead of the usual sheet-iron circular tubing.

Electricity Distribution.

The main switchboard is situated in the power house, and is fully equipped for the first installation, with provision, in the shape of spare panels, for the succeeding installations. The panels are of white marble, and are fitted with the necessary switchgear, meters, circuit breakers, &c. From experience at Poole with switchgear operating in gas-works atmosphere, it was decided to increase the size of the frictional copper segments to obtain increased life; the knife switches being made 100 p.ct., and the circuit breakers 200 p.ct., larger than normal practice.

In order to reduce the number of long cables to a minimum, the whole of the power for the retort house and coal and coke-handling plant is dealt with by a separate cable carried to an auxiliary switchboard, situated in the retort house. This board is of black slate and is totally enclosed in a dust-proof glass panelled housing.

REINFORCEMENT FOR RETORT HOUSE FOUNDATIONS.

Compressed Air Plant.

The air compressors are both of the Reavell rotary type, one steam and the other electrically driven. They are of 153 c.ft. of free air per minute capacity, and compress to 100 lbs. per sq. in.

Gantry Cranes.

Travelling gantry cranes span both the exhauster bay and the main bay, and a horizontal gap of adequate size has been left in the wall dividing the power house from the fitting shop, so that the crane can pass right through into the fitting shop, taking with it any machinery requiring attention—which can in this way be taken direct to the appropriate lathe or machine which is to deal with it.

At the end of the main block, adjoining the power house, are situated the workshops, and above them the messrooms, bathrooms, lavatories, and cloakroom.

Telpher.

The telpher is designed to connect the retort house, coke hoppers, main block buildings, ash washing plant, and cableway terminal hoppers. It makes a complete circuit in passing these various points, and for the first and second sections of the works will operate without a rail switch of any kind—a decided advantage in a telpher.

Relief Holder.

The relief holder, constructed by Messrs. Clayton, Son, & Co., is of 400,000 c.ft. capacity. The steel tank is carried

on a concrete raft on the clay 13 ft. below ground-level. It is placed where it can be readily seen from the water gas house, and is designed with two lifts, spirally guided, and with a special guard plate running round the curb of the outer lift to prevent oil tar picked-up by the inner lift from overflowing and running down the outside of the outer lift.

Ammonia Extraction Plant.

The ammonia extraction plant consists of a Livesey washer, rotary ammonia washer, and a special lead-lined acid washer. No water is used on this plant. The weak liquor from the retort house is used in the rotary washer, and the ammonia left in the gas is absorbed in the acid washer, the contents of which are kept at about 4 p.ct. acidity. This system has been in use at Poole for many years, and considerably reduces the volume of liquor made. The concentrated acid solution of sulphate of ammonia is used up in the saturator. The whole of this plant was supplied and erected by Messrs. W. C. Holmes & Co.

Tar and Liquor Storage.

The tar and liquor from the retort house are received in two small boiler tanks of about 2000 gallons capacity each, placed below ground-level. These tanks are arranged so as to promote the separation of tar and liquor; these latter being pumped separately to overhead storage tanks. These main storage tanks are of mild steel, covered, and of 200,000 gallons capacity each, standing on a reinforced concrete raft carried on piles. The evaporation of ammonia from the liquor storage is prevented by a 3-in. layer of gas oil. The liquor inlet, which enters at the top, is carried to the bottom under the oil level, and is fitted with an open pipe at the top as a syphon break.

In addition to the two tanks for tar and liquor, there is a third tank of a similar size and construction for gas oil. These three tanks were originally carried on a reinforced raft placed direct on the ground, which at this point had been reclaimed for many years. When the first tank was under test, and only one-third full, it was found that the raft had settled at one end some 4 in., and serious cracks had developed in the raft itself. As this represented the effect of some 600 tons only out of a full load for the three tanks of over 3000 tons, it was obvious that it would be necessary to transfer the tanks to new foundations supported on the requisite number of reinforced concrete piles, and this was eventually done. This experiment was unfortunate in some respects; but it at least served to justify the policy which had been generally adopted with regard to the foundations of the rest of the works.

Tar Treatment Plant.

Near the tar and liquor storage tanks is placed the plant for dealing with the tar required for road tarring, &c. A 3000 gallons per day Wilton dehydrating plant has been removed from the Poole Works and re-erected on the new site. Alongside has been erected a new cascade type of plant of 10,000 gallons per day capacity, supplied by Messrs. Clayton & Co. Mixing tanks for preparing a special mixture of tar and bitumen for road surfacing have also been provided; and the storage and delivery tanks for the prepared tar and the tar and bitumen mixture are arranged in line with the general tar plant. These delivery tanks are erected sufficiently high above ground-level to allow of the barrels being filled on a loading platform at the level of the motor lorries which transport the tar. In close proximity to these plants a small tar macadam plant has been erected. This has made the tar macadam used in the works paths and secondary roads, and is now available for making macadam for footpaths for the various local authorities.

Ash Washing Plant.

The ash washing plant, which is constructed in duplicate, is situated on the line of the telpher, and deals with the ashes from both the Poole Works and the Pitwines Works. An inclined rotary cylinder separates the clinker from the coke by means of an internal angle-iron spiral and a descending stream of water. The coke is, by reason of its lower specific gravity, washed to the bottom end of the cylinder, and the clinker is carried to the top of the spiral angle-iron. The water used is circulated continuously by a centrifugal pump, and the fine dust is collected as sludge by sedimentation in settling tanks. This system has proved very effective for many years past in the Poole Works in a plant costing approximately £750. The cost of coke recovery over 22 months (excluding interest on capital) was 3s. 9d. per ton of recovered coke.

Purifiers.

No provision has been made for the construction of additional purifiers for the first section. This is due to the fact that the existing purifiers have a reserve capacity which will serve adequately for the requirements of the Company for the next two years.

Sulphate of Ammonia Plant.

The designs for the sulphate plant and house have been completed, and the contract placed, but no work upon them has been commenced at the time of writing. The whole of the liquor from both works will be treated by this installation, and provision has been made in the general lay-out for three sections, one only of which will be put in at first. The output of this section will be 6 tons of dry neutral salt per day, when working with 8-oz. liquor. Except for two special features the plant, which will be erected by the Chemical Engineering Company, substantially follows present-day standard practice. One of the special features is the placing of the liming or soda ash plant (whichever is in use) at the top of the building, so that the alkali enters the lime still by gravity, thus doing away with the lime pump. The second novel feature is the arrangement for collecting the hot sulphate from the saturator and storing it in a steam-jacketted vessel in readiness for the centrifugal—an arrangement based largely on patents taken out by Dr. Lessing. A microscopical examination of the salt as it came from the saturator and as it left the centrifugal in ordinary practice showed a large increase in the number of very fine crystals, due undoubtedly to the lowering of the temperature of the magma on the draining board. This not only promoted the deposition of fine crystals in the super-saturated solution, but also retarded the subsequent drying operations. To overcome these objections, a steam-jacketted Monel-metal vessel has been designed to hold enough sulphate for one centrifugal charge; and the magma from the saturator is discharged into it. An overflow from the vessel allows the mother liquor to run back to the saturator by gravity. The crystals of sulphate fall through the overlying mother liquor in the receiver, and a certain amount of suspended impurities and colouring matter is thereby washed out. A bottom discharge valve allows the charge of sulphate to run into the centrifugal by gravity. By this arrangement it is anticipated that a hotter charge containing fewer small crystals, and of an improved colour, will be obtained.

Railway Sidings.

The Pitwines Works are situated alongside the main line of the Southern Railway; but until the present works were projected, no sidings were installed. The first stage in the new works was the construction of sidings complete with railway weighbridge, and the provision of a petrol shunting locomotive and a 5-ton curved jib crane. Altogether some 2000 yards of standard gauge sidings have been laid; and coke, tar, acid, oil, oxide, fire goods, and general stores can now be handled direct from truck to their respective stores, or *vice versâ*.

Standardized Plant.

The gas valves throughout the works are Holmes' double-faced "Western" type, turning clockwise to open. The electric generators and all the motors are made by the British Thomson-Houston Company, and all the pumps used are of the Weir type.

Mains.

As the whole of the works stand on ground reclaimed by means of ashes, which would have a serious corrosive effect upon the mains, it has been necessary to protect them very carefully. This has been done by coating them throughout their length with a 6 in. envelope of pugged clay, recovered for the purpose from the relief holder foundations, and mixing with the trench-filling a liberal supply of precipitated chalk from the softening plant of the Company's water-works.

The whole of the reinforced concrete construction (with the exception of that required for the cableway stations and bridges, which were put in by the Mitchell Conveyor Company) together with the making and driving of the piles for the foundations, has been undertaken by Messrs. Thos. Vale & Sons, of Stourport.

In conclusion, I must put on record my indebtedness to Mr. Roy Irving, the Assistant Engineer, who has helped me in the design and erection of the new works. His capacity and zeal have been a very real help, and he has displayed all the keenness that one would expect to find in the son of one of our most respected colleagues.

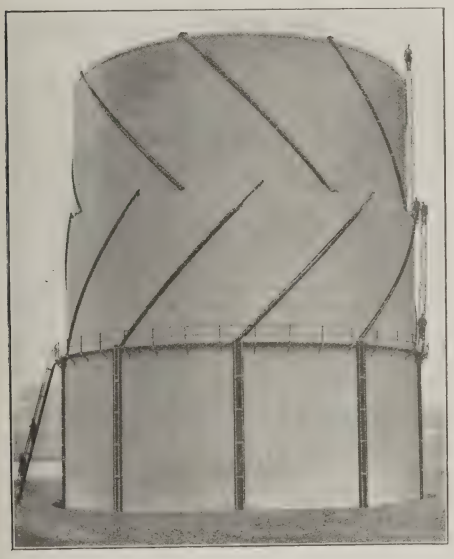
I must also pay a tribute to my Directors for the broad, sympathetic, and understanding spirit in which they have received and considered all the recommendations made to them. I realize that I am fortunate in having as Directors men used to handling big problems—men of outstanding eminence in their own respective spheres, and therefore well qualified to take the broad view and to inspire rather than to hamper their executive officials.

English Gas Men Spend.—This is the title given to the following editorial paragraph, which appears in the issue for March 21 of our American contemporary the "Gas Age-Record:" Miracles come to pass in England. Last year the British gas companies gave £75,000 to provide the marvellous exhibition of gas service and gas appliances that was shown at the British Empire Exposition at Wembley. American visitors were unanimous in their praise of this exhibit, and all concurred in the opinion that it was the best exhibit of the thousands there. We wonder what would happen if American gas men were asked to invest such a sum, equivalent to about $350,000 at the rate of exchange reigning last year, in an enterprise where they could not see the dollars flowing back to repay them for those they had spent. It is a thought to conjure with. And yet we believe that we are the foremost nation in the world when it comes to advertising.

NEW GASHOLDER AT HONLEY.

A large company of representative public men of the Holme and the Colne Valleys assembled at the Honley Urban District Council Gas-Works last Thursday, to participate in the inauguration of the new holder, which is described below. The gas was officially turned on by Mr. G. T. Oldham, J.P. (the Chairman of the Council).

Opening the proceedings, Mr. J. W. Broadhead said they were assembled to celebrate the official opening of Honley's new holder. Apart from the fact that he had the honour of representing there that morning the firm of Messrs. Robert Dempster & Sons, he might say the holder had not been installed before it was wanted. This would readily be understood when he stated that, with a maximum output during the 24 hours of 190,000 c.ft. of gas, there had been available storage of only 42,000 c.ft. How Mr. Harry Marsden (the Gas Engineer) had managed to keep the supply going was, he might say, without flattery, a miracle. Even with the new holder, Honley had only what was considered safe and proper storage for the economical carrying-on of the undertaking. Mr. Marsden would now, without the past anxieties, be able to give the consumers all the gas they required, and at a suitable pressure and of a much more uniform quality than he had been able to do in the past. The new tank held about 4000 tons of water; and it had not a single leak when filled. In connection with the contract, one of Messrs. Bryan Donkin's boosters had been installed. He had pleasure in asking Mr. Oldham, who had taken a great interest in the undertaking, officially to turn on the gas from the holder to the town; and he expressed the hope that the new structure would fulfil all that was anticipated from it, and always give great satisfaction.



The Two-Lift Spiral-Guided Holder at Honley.

The gas was then turned on by Mr. Oldham, who said he had the pleasure of seeing the first rivet put into the tank, and had put one in himself. Everything had gone on most satisfactorily, and now they had a fine holder, which was a credit to Messrs. Robert Dempster & Sons.

Mr. Broadhead asked Mr. Oldham to accept, as a memento of the occasion, a solid silver tea and coffee pot, suitably inscribed. Accepting the gift, Mr. Oldham declared that any souvenir was uncalled for; but nevertheless he should treasure the present, which would serve him well, as would the new holder the town of Honley.

After the ceremony, the company lunched together, when several toasts were honoured. "The Honley Urban District Council Gas Undertaking" was proposed by Mr. F. Littlewood, and responded to by Mr. Oldham. That of "The Contractors" was submitted by Councillor G. Borwell, and acknowledged by Mr. Broadhead. The toast of "The Visitors" was submitted by Councillor J. E. Heap (the Vice-Chairman of the Honley Council), and replied to by Mr. F. H. Robinson, of Harrogate (the President of the Manchester District Institution of Engineers). "The Engineers" was submitted by Mr. A. Whiteley, of Kirkburton—Mr. Marsden responding.

The Holder Described.

The new gasholder is of the spiral-guided type, with two lifts, in a steel tank. It has been constructed by Messrs. Robert Dempster & Sons, Ltd., of Elland, and is fitted with their "Elland" patent ball-carriages, and also their patent ladders. The holder, when fully inflated, stands 85 ft. above the ground—the outer lift being 75 ft. 6 in. in diameter by 30 ft. deep, and the steel tank 77 ft. in diameter by 30 ft. 6 in. deep—and has a capacity of 250,000 c.ft. In order to meet existing local conditions, the inner life throws a pressure of 8 in.

This holder is a further example of Messrs. Robert Dempster & Sons' improved system, which is now becoming well known, of guiding spiral holders by means of balls in place of rollers; and though this principle of guiding spiral holders was only placed on the market by them about two years ago, eight holders have already been completed, the first of which has now been working nearly eighteen months. It so happens that most of these eight holders are placed in very exposed positions, and during the past winter have been called upon to withstand gales of hurricane force. They have earned great praise from engineers who have had the opportunity of observing their very steady working under these trying conditions.

At the risk of repeating our former observations on this type of holder, we feel that a short description of the system would not be out of place. The essential differences in Messrs. Robert Dempster & Sons' improved method of construction of spiral holders lies in the carriages and the rails. Instead of, as in the ordinary system, the spiral rail passing through one or two pairs of flanged rollers, the rail (which has a circular groove on either side) passes between two pairs of case-hardened steel balls 2 in. in diameter. The rail is also provided with a second and smaller groove between the rail flange and the ball-groove, which serves to carry rain-water, &c., into the tank or cup without its having to pass promiscuously over the sheets.

Although this at first sight appears to be putting a gasholder on ball-bearings, this is not essentially true in the accepted sense of a ball-race. In an ordinary ball-bearing, the balls are free to revolve and travel in the direction of the wheel or shaft upon which it is mounted, whereas in the ball-carriage the ball is confined to a cup which prevents the ball travelling in the direction of the rail.

This point, which at first appears to be detrimental to the system, has been turned by the makers to their advantage. The diameters of the cup in which the ball rests, the ball, and the groove in the rail are arranged so that the ball is never in contact at two points diametrically opposite. The result of this is that the ball is continually spinning on an axis at right angles to the rail-face; and this axis, continually changing, prevents undue wear of any parts of the surface of the ball.

The ball-carriages themselves are made of forged steel of extremely heavy sections, and have a very large factor of safety against any stresses which the holder may be called upon to withstand. Another point of note in these ball-carriages is that all sliding parts are eliminated; the expansion and contraction of the holder being allowed for in the movement of the balls. The carriage is also fitted with a double swivel, which causes the balls automatically to set themselves parallel with the rail under any conditions, thus giving an equal bearing.

The rails themselves weigh nearly twice as much as the standard section rails used for spiral-guided holders, and are considerably stronger—special rolls having been mounted for producing them.

The Late Mr. H. E. Jones.—In connection with the funeral of Mr. H. E. Jones, brief reference was made in last week's "Journal" to the memorial service held at the Savoy Chapel, and the names of some of those present were mentioned. It should be added that the Society of British Gas Industries were represented by Mr. Samuel Cutler (Hon. Secretary), Mr. F. G. Cockey, Mr. Arthur L. Griffith (Secretary), and a representative of Messrs. Gibbons.

Treatment of Water Gas Tar.—Mr. J. D. Smith (Engineer and Manager of the Belfast Gas-Works), in a report to his Committee, says: "For a great many years—in fact, since the introduction of the carburetted water gas plant, I believe—serious trouble has been experienced with water gas tar. Very frequently this tar, immediately after leaving the plant, formed into an emulsion; and as it was useless to contractors in this form, we had to devise means for storing it until the tar and water separated. Many attempts were made to get over the difficulty, but all failed. I have had brought to my notice recently a water gas tar dehydrator manufactured by Super-Centrifugal Engineers, Ltd., of London; and the results of tests made by this plant on our tar have been eminently satisfactory. I am satisfied that the plant is efficient, and as the price is only £250 I recommend the purchase of one of these machines." The recommendation was adopted.

SCOTTISH JUNIOR GAS ASSOCIATION.
(WESTERN DISTRICT.)

The ordinary monthly meeting of the Western Juniors was held on March 28 at the Royal Technical College, Glasgow, when Mr. John M'Isaac presided over a good attendance.

The Hon. Secretary intimated that the annual general meeting would be held on Saturday, April 18.

SELECTING AND TESTING WROUGHT-IRON TUBES.

By John M'Intyre, of Glasgow.

All works should see that their tubes receive some test. A neat, reliable, and inexpensive plant can easily be rigged up at the end of the boiler house. Such a plant was in use in Glasgow up to about three years ago, and rendered excellent service. It consisted of a steam connection from a boiler, provided with a screw-down stop valve (as there is no reducing valve, this one serves the dual purpose of a stop and reducing valve), a pressure gauge to read a little above the test pressure, a tee connection with relief cock, a set of reducing couplings to accommodate various sizes of tube, and also a pair of suitable wooden trestles and V blocks with clamp, to hold the tube in a convenient position for working.

Method of Testing.

Take the length of tube to be tested, look over the outer surface, see if it is free from blemish, note the screws at both ends, try-on the coupling, then hold up to the light, look through inside, and see if there are any blisters or scale or anything abnormal. Next screw on to the coupling at the pressure gauge, and fix the coupling with a relief cock. Open the latter, so as to exhaust the air in the tube when the steam is turned on gently. When the air is removed, allow the steam to blow for a few seconds. This acts as a good scourer, and helps to cleanse the inner surface of the tube. Check the steam, close the relief cock, allow the pressure in the tube to rise to the agreed figure—(say) 25 lbs. per sq. in.—then shut-off the steam. Allow pressure to remain on for a little; and any defects will soon begin to show. The outer surface may be tapped lightly with a small hand hammer while the pressure is on, as this may assist in revealing any defect hidden by rust, scale, &c.

Some people dislike steam testing plants for wrought-iron tube, alleging that the steam leaves them wet, and they thereby become rusty. This is not the case.

Tubes at the street mains section were tested by a plant like this until the removal of the Dalmarnock Gas-Works workshops to their new premises about three years ago. Then, with no steam boiler at hand, we had to look around for some other method of testing.

An old ⊐-shaped hydraulic main was set up, and fitted with a fixed rod at the back and two swivel arms, between which a 12 ft. length of tube could be placed. The arms were swung into the box, which was filled with water. Air pressure was applied to the tube, and any defect was made visible by the air escaping causing small bubbles in the water. The tube, if satisfactory, was then removed from the trough and placed in the rack. This worked well, except for the fact that it was laborious to raise the air pressure by hand. However, the results were satisfactory enough to justify the department spending some money on a plant of the same type, but with a power-driven supply of air pressure. This was done, and the plant at present in use at the street mains section, Dalmarnock, was laid down.

The plant consists of a rectangular testing bath of mild steel plate, capable of testing tube up to about 12 ft. long, a large cylindrical receiver in which air can be stored at 30 lbs. per sq. in. pressure, a small air pump belt-driven from a wall shaft, the shaft in turn being driven by a 1½ h.p. Gardner gas engine. The pump belt striker is actuated by a cut-off device made by Messrs. Aerograph, Ltd., of London, which, when the predetermined pressure of 30 lbs. is attained at the receiver, stops the pump, and starts it up again immediately the pressure falls below this figure. When this new plant was put in operation, other items were introduced so that every aspect of the question could be taken into account, and nothing left to chance. These were a measuring rod to check lengths of consignment required of a specified length, a weighing machine to check the weight per foot run, a gauge bar to check the outside diameter, rods to ensure the correct inside diameter, and a plate gauge to test the thickness of the metal. To see how screws fit, a set of average couplings are used as gauges.

Table of Standard Sizes for the Range of Tubes in Common Use in Glasgow.

Nominal Bore. Inches.	Approx. External Diameter.	Screw. Whitworth Gas. Threads. per Inch.	Gas Quality. Thickness. W.G.	Gas Quality. Weight. Ft.-Lbs. Oz.	Steam Quality. Thickness. W.G.	Steam Quality. Weight. Ft.-Lbs. Oz.
⅛	⅜	19	14	0 6½	12	0 7¾
¼	½	19	13	0 9	11	0 11
⅜	⅝	14	12	0 13	10	0 15¾
½	1 7/16	14	11	1 2¾	9	1 6¾
1	1 7/16	11	10	1 9¾	8	2 0¼
1¼	1 11/16	11	9	2 5¼	7	3 0
1½	1¾	11	8	2 14¾	6	3 7¼
2	2⅜	11	8	2 12¾	6	4 14¾
3	3½	11	7	6 5½	5	8 2¾
4	4½	11	7	8 3¾	5	11 8½
6	6½	11	7	13 6	5	17 4

Discussion.

The Chairman mentioned that many people thought all testing was done by the manufacturers, and emphasized the importance of giving the matter serious consideration. The approximate cost of the new machine described by Mr. M'Intyre was £140. Would Mr. M'Intyre give the meeting some data regarding the running costs, number of pipes tested per hour, and the possible output of the machine?

Mr. Simpson (Greenock) was of opinion that all pipes should be tested in a simple manner at the gas-works, before being sent out for fitting. The small expense incurred in setting-up a plant for this purpose would be more than met in the assurance of general safety.

Mr. M'Intyre explained that with the old type of steam testing they were able to handle 10 to 12 pipes per hour; but with the new plant, the output was more than doubled. The cost of testing the pipes was approximately 0·28d. per ft. The output from this machine was estimated at 300,000 ft. per annum. The percentage of condemned pipes would be about 1 p.ct., while he had known of three-quarters of a delivery being condemned for scale and blister, due to bad quality of iron.

THERMAL BALANCE-SHEETS.

By R. F. W. Blakey, of Stirling.

Theoretical Considerations.

The first real investigations of the heat losses in the destructive distillation of coal to form gas, tar, and coke were carried out by Mahler, and later by Euchêne. A survey of their results shows that the decomposition of coal in a gas retort is an endothermic reaction. The loss of heat is calculated as from 2 to 6 p.ct. of the original thermal energy of the coal. It varies with the different types of coals, being greatest with coals of a high oxygen content—a fact which indicates that the oxygen-bearing compounds are responsible for the endothermic character of the coal. Lewes states that the loss of original heat on destructive distillation of coal is about 480 B.Th.U. per lb.

The approximate distribution of the thermal energy in the products of distillation of coal at high and low temperatures is as follows:

1 Ton of Coal = 300 Therms.

	High Temperature.		Low Temperature.	
Gas	72		35	
Tar	17		26	
Volatile matter in coke	3	199	29	223
Coke	196		194	
Loss	12		16	
Total	300		300	

These figures do not take into account the heat supplied externally to effect carbonization.

The loss of heat appears to be greater if the carbonization is carried out at a low temperature; and the reasons given for this are that the loss is augmented by the exothermic reactions predominating during the first period of the distillation, when the rate of evolution of therms is greatest, and that some of this heat is lost as sensible heat, whereas during the process of complete carbonization some of the sensible heat is converted into potential heat.

The gas industry is concerned with the gaseous thermal yield; and the greatest economy must be attained by a method which is not wasteful in volatile therms. The term volatile therm is taken to apply to the total therms in both gas and tar; and to a certain extent these are interchangeable. Partially to convert therms in low-temperature tar into gaseous therms, leaving as residue high-temperature tar, is a reaction which is recognized to take place in every high-temperature carbonization process. This is not to be compared with the interchanging of high-temperature tar therms for gaseous therms. In this instance, cracking of tar to gas is doubtful economy—first owing to pitch troubles; secondly, the yield of therms in the gas which results from this cracking is small. The tar is so altered as to be of little value to the tar distiller.

In horizontal retorts working under the best conditions, with good coal, and at a combustion chamber temperature of 1300° C., it is possible to obtain a high yield of therms in the gas, and also to retain a just proportion in the tar. The gas from this method of working is low in inerts; and consequently the density is lower than that necessary for efficient use for lighting purposes. The calorific value is also higher than is necessary. Carbonization at a still higher temperature would result in a reduction in the calorific value, and would also raise the density of the gas by dilution with the poor gas obtained by cracking the tar; but this method is not to be recommended, since there is a greater loss of the original thermal energy. The yield of therms in the gas may approach a higher figure than by the process of carbonization at moderate high temperature, but only at the expense of the tar. To convert tar into gaseous therms may appear to be good practice; but when

fully considered, it is seen that the game is not worth the candle. There are several remedies at hand to reduce the calorific value of the gas—namely, dilution with water gas, producer gas, or waste gases. By any of these methods good yields of gaseous therms may be obtained, without undue degradation of gas or tar.

Practical Results.

It may be of interest to consider some of the results obtained in Stirling with horizontal retorts and a Humphreys and Glasgow blue water gas plant. The carbonizing plant consists of mechanically-operated horizontal retorts, 20 ft. long and 22 in. by 16 in. cross-section.

Each oven is heated by an internal producer on the discharge side. The ascension pipes are on the discharge side. The plant was erected in 1907-8, and extended in 1910, and is specially adapted for use with the types of coal mined in the district. The average weight of charge per retort is about 8 cwt. The retorts are silica segmental.

The blue water gas plant has a capacity of 400,000 c.ft. per day, and is fitted with exhauster, station meter, and relief holder. It is an independent unit, all the gas being metered; thus control of the proportions of water gas added to the foul gas can be carried out satisfactorily. The coal used in the retorts is a mixture of Bannockburn, Plean, and Lanarkshire in the approximate proportions of 56, 17, and 27 p.ct. respectively, with the following average analysis:

	P.Ct.
Moisture	3·50
Volatile matter	35·08
Fixed carbon	57·50
Ash	3·92

Calorific value of coal as received = 13,803 B.Th.U. per lb.

The foul gas has an average analysis as follows:

	P.Ct. by Vol.
Hydrogen	53·0
Methane	30·8
Heavy hydrocarbons	3·4
Carbon monoxide	6·2
Carbon dioxide	1·3
Oxygen	0·4
Nitrogen	4·9

Average calorific value of gas = 591·4 B.Th.U. per c.ft.

The results taken over a period on the carbonization plant on the basis of 1 ton of coal retorted are as follows:

Volume of gas (corrected 30 in. and 60° Fahr.)	10,500 c ft.
Yield of tar	98 lbs.
Yield of coke	1434 lbs.
Coke used for producers	344 lbs.
Coke used for producers per 100 lbs. coal	15·3 lbs.
Temperature of combustion chambers	1270° to 1300° C.
Temperature of coke as pushed	950° C.

Approximate Thermal Balance.

Therms in 1 ton of coal		309·16
,, in gas	62·10	
,, in tar	15·65	
,, in coke	03·53	
,, in coke for producer		48·84
Therms not recovered—		
Loss from original therms in coal	27·88	
Coke used in producers	48·84	
	358·00	358·00

No allowance is here made for heat recovered in retort carbon.

The water gas is added to the foul gas after cooling to approximately atmospheric temperature.

Average calorific value of water gas	310 B.Th.U. per c.ft.
Water gas in mixed gas	39·9 p.ct.
Calorific value of mixed gas	481 B.Th.U. per c.ft.

Analysis of Mixed Gas.

	P.Ct. by Vol.
Hydrogen	52·4
Methane	19·2
Heavy hydrocarbons	2·1
Carbon monoxide	19·2
Carbon dioxide	2·3
Oxygen	0·4
Nitrogen	4·4
Gaseous therms per ton of coal	84·03
Gaseous therms obtained from coke (per water gas)	21·93

The efficiency of the water-gas plant is taken at approximately 58 p.ct.

The yield of therms per ton of coal retorted has been augmented to the extent of 21·93, at the expense of the thermal energy of some of the coke, and a suitable mixed gas has been obtained. Loss of volatile therms has been avoided by reducing the cracking process at high temperatures to a minimum; and any volatile matter remaining in the coke is partially taken advantage of in water gas manufacture. The conversion of therms in coke into gaseous therms is a process of about 55 to 60 p.ct. efficiency, and could be even higher if waste-heat boilers were employed; while the cracking of tar is only reckoned as 25 p.ct. efficiency at best, and then it is also attended with grave troubles in the retort house.

Thermal Efficiency of Water Gas Production.

Gas made per ton (gross) coke	61,035 c.ft. (corrected)
Gas made per run	2,100 ,, ,,
Coke to generator per 1000 c.ft. of gas made	36·7 lbs.
Dry coke to generator per 1000 c.ft. of gas made	33·03 ,,
Steam to generator per 1000 c.ft. of gas made	38·0 ,,
Dry coke to generator per ton of coal retorted	226·8 ,,
Equivalent in coke for steam raising for generator per ton of coal retorted	27·8 ,,
On basis of 1000 c.ft. water gas made.	
Input of Thermal Energy—	
Therms in coke	4·6879
Therms in steam (70 p.ct. boiler efficiency)	0·5754
Total	5·2633
Output of Thermal Energy—	
Therms in 1000 c.ft. gas	3·1000
Thermal efficiency of plant (excluding steam to drive turbine blower)	58·9 p.ct.

The determination of the thermal efficiency of the water gas plant gives a fairly reliable means of checking the working of the plant as a unit, and it is useful to note the drop in this efficiency as the plant continues in daily use. The steam to the turbine, being of constant value, does not affect the comparative figure given for the plant efficiency.

Dilution of Coal Gas with Air.

Dilution with air is in the above instance not necessary except in such small proportions as are needed for purification purposes; and then it is added at a point where the gas has attained atmospheric temperature. The addition of air in the retort house should certainly be avoided, if the maximum thermal yield is to be obtained. Air admitted at retort doors is particularly wasteful, since it not only dilutes the gas, but causes tar to be subjected to a process of cracking in the ascension pipes. The latter are virtually converted into small tar distilleries, with partial combustion of the products taking place at the same time.

It is not always realized that the conditions of carbonization can be modified to give the required distribution of therms; and it is not a difficult matter to determine the conditions likely to be most remunerative and suitable with existing plant. It would appear that the practice to be adopted is to use charges sufficiently heavy to avoid free space in the retorts, thus preventing the degradation of gas at high temperature, and to carry out the carbonization as rapidly as possible, without making use of excessively high temperature.

The thermal balance-sheet is as important to the successful gas undertaking as the financial balance-sheet, since therms have to be bought, and afterwards sold in a more convenient form. It is a great pity that coal is not purchased on a thermal basis. It has been suggested that the smaller gas undertakings in each district should have a fully equipped technical laboratory available for their joint use. The first duty of this scheme would be to assure the delivery of the therms—and in the proper form, for two coals of the same calorific value are not necessarily of the same gas-making value. The day is not far distant when the smallest of us will demand satisfactory proof that every truck load of raw therms delivered is graded.

I would like to acknowledge the help afforded by Mr. Smith, of Stirling, in allowing me to use all data required for this paper.

Discussion.

Mr. Simpson (Greenock), while appreciating the manner in which Mr. Blakey had dealt with his subject, said he was inclined to differ very much from him. Mr. Blakey had treated his subject entirely from the point of view of coal conservation, while he was of opinion that they in the gas industry should give their first consideration to the financial aspect of the case. The financial balance-sheet was infinitely more important than the thermal balance-sheet; and their first duty should be to sell cheap gas. Efficiency would follow in the natural course of events. With regard to Mr. Blakey's remarks relating to dilution with waste gas and producer gas, he hoped this would not be taken up. He instanced the serious effect this would have on the mains.

Mr. Blakey, in reply, said that he had studied his paper purely from the technical point of view, and thought that gas made from tar instead of coke was not good business. In his opinion, tar was too valuable to break up for the manufacture of gas. With regard to dilution by waste and producer gases, he still thought that this could be carried out in small works where there was no water gas plant.

Books Received.—From Sir Isaac Pitman & Sons, Ltd., we have received the following books: "Low-Temperature Distillation," by Sidney H. North and J. B. Garbe (price 15s. net); "The Carburettor Handbook," by Ernest W. Knott (price 10s. 6d.); and "The Metal Worker's Practical Calculator," by J. Matheson (price 2s. net). The Society of Chemical Industry have forwarded a copy of Volume IX. of their "Annual Reports of the Progress of Applied Chemistry." The price of this is 7s. 6d. to members of the Society, and 12s. 6d. to non-members, post-free.

LONDON AND SOUTHERN DISTRICT JUNIOR GAS ASSOCIATION.

Visit to Woolwich Arsenal.

On Thursday afternoon, April 2, nearly a hundred members of the Association visited the Royal Arsenal, when, under the guidance of their President, Mr. W. Newton Booth, B.Sc., who was ably assisted by Messrs. Manchee, Good, Sheryer, and Ferris, they inspected the principal shops of the Royal Ordnance Factories. A visit to the Arsenal—as Mr. Booth remarked—must always prove of great interest to the Britisher; and when the visitor happens to be an engineer, this interest is doubly strong. The afternoon was thoroughly enjoyed; and all members of the Association must have realized the full meaning of the term "British engineering," when they were brought into contact with the extreme accuracy and superb skill without which the production of the mighty guns would be impossible. Perhaps the thought crept in that all this skill could be used for less irrational purposes; but as the party were representative of a gas, and not an ethical, society, this thought need not be pursued further.

An "Industrial Town."

The Arsenal is an enormous place; its area being about four square miles. To visualize it mentally, one has to adopt the "Beckton" outlook. On first visiting Beckton, one is told that there are about sixty miles of railway track; and on entering the Arsenal, which can well be termed an "industrial town," one learns that the length of track must be reckoned not in tens, but in hundreds, of miles. It will be remembered—certainly by those who endeavoured to fight their way to the 'buses in Beresford Square—that during the war there were employed at the Arsenal no fewer than 120,000 men—a number now reduced to a total of about 8000.

The Shops Visited.

The tour of inspection, which occupied nearly three hours, commenced with a Lancashire boiler house which is used for coal testing. Then, in turn, the members passed through the steel foundries; the forging shops; the heavy turneries, where there are some of the largest lathes in the country; the central power station, in which are installed four 1500-kw. D.C. sets driven by steam generated in Babcock and Wilcox water-tube boilers fitted with mechanical grates; the hydraulic power house; the north boring mills; and the new drop-stamping shop, which is in course of construction. It is intended to equip this shop with gas furnaces—indeed, at the time of the visit, one furnace was already in operation. Then the visitors were shown the pipe-fitting and furnace shop, where some of the small gas furnaces are made and tested. In this shop a small high-temperature crucible furnace was seen under test. Thence the party passed through the gun gantries, where the naval guns are stored, into the light gun factories, which comprise machine and tempering shops. Inspection of the tempering shops and boring mills for the heavy guns, the miscellaneous machine shops, where the intricate parts of the carriages are produced, and the light forges completed a tour which, with its host of vivid impressions, will long remain in the memory of members of the London and Southern District Junior Gas Association.

Thanks to the President.

Tea was then served, after which Mr. A. Broadbent (Hon. Treasurer of the Association) proposed a vote of thanks to Mr. Reginald Townsend (the Chief Superintendent of the Ordnance Factories) and to Mr. Newton Booth and his assistants. Their President, said Mr. Broadbent, must feel very gratified with the excellent attendance.

Mr. A. S. Stainer (Brentford Gas Company) seconded the vote, saying that the visit had been regarded by the Association as a very real privilege.

Mr. Newton Booth said that, to any citizen of the British Empire, a visit to the Arsenal must prove of interest—an interest which must be all the greater when the citizen happened to be an engineer. The standard of engineering work carried out at the Arsenal had a beneficial effect on the quality of engineering generally. After expressing his pleasure at seeing so many present, he said that all such visits should be well attended. Each member owed it to himself and to the Association.

"Safety First."—"Safety First," the official journal of the National "Safety First" Association, is a monthly publication, at the price of 1s. to the public, though to members of the Association it is included as part of the subscription. A feature of the first issue is a "Foreword" by the Home Secretary (Sir William Joynson-Hicks, Bart.), who is President of the Association for 1925. The industrial side of the movement is dealt with in articles by Sir Thomas Legge (Senior Medical Officer, Home Office) and by the Association's Safety Engineer. The address of the Association is 119, Victoria Street, S.W.

CORRESPONDENCE.

[We are not responsible for opinions expressed by Correspondents.]

Spirally-Guided Flying Lifts.

Sir,—With reference to the application for Patent No. 229,128/25 by Mr. William Blakeley for the application of spiral system flying lifts for guide-framed gasholders, extracts from which appeared in your issue for March 18, this is certainly not a new "invention," as Messrs. C. & W. Walker, Ltd., erected in 1897 a four-lift gasholder for the Guildford Gas Company, to designs prepared by the late Sir Corbet Woodall. The inner lift of this was 115 ft. in diameter by 24 ft. deep, and was spirally guided.

The first flying lift was, I believe, introduced by the late Sir George Livesey in connection with the Rotherhithe holder for the South Metropolitan Gas Company, some time before the East Greenwich holder was built; but this was not spirally guided. As a matter of fact, there is no advantage whatever, but several disadvantages, in adding spiral guides to the flying lift of a four-lift standard-guided holder.

R. J. Milbourne.

Lilleshall Old Hall,
near Newport, Salop.
April 6, 1925.

Mr. Philip Moon's Presidential Address.

Sir,—I regret to find that there was an error in the table of my Presidential Address [appearing at the bottom of the second column of p. 40 of the "Journal"] in which it states that a unit of electricity is equal to 3440 B.Th.U. The figure of equivalent therms—namely, 169·4 millions—is worked out on a basis of 3420 B.Th.U. per unit, which is, I think, nearer the accepted equivalent.

Philip G. G. Moon,
General Manager.

REGISTER OF PATENTS.

Coking Batteries.—No. 215,306.

Koppers Company, of Pittsburg (assignees of J. van Ackeren).

No. 22,805; Sept. 11, 1923.

Convention date: May 4, 1923.

This invention relates to coking batteries with heating walls operatively connected in pairs by ducts extending transversely of an intervening coking chamber, and reversible regenerators serving the heating walls. Batteries constructed on the above principle are described in the specifications of Joseph Becker, Nos. 171,117 and 205,459 [see "Journal," Vol. 168, p. 399].

This invention has for its primary object the provision of an oven embodying the transverse connection of heating walls, in a structure that may be operated either with coke-oven gas or as a combination oven, and yet may have the regenerators reduced to about one-half the number shown in the said prior specifications.

The invention provides the following simplifications and conveniences in construction and operation: Elimination of any supporting walls other than the usual pillar walls beneath the coking chambers; a workman is enabled to walk into a regenerator chamber, thereby greatly facilitating repairs and replacements; the heating walls and the coking chambers above the regenerators can be made of relatively great height with a relatively small increase in the height of the battery structure as a whole; and a reduction amounting to approximately one-half of the flow boxes and reversing devices required for controlling and reversing the flow of the various gases through the regenerators and flues.

Thirteen drawings and a full description are included.

Manufacture of Coal Gas and Water Gas. No. 229,042.

Neath, J., and Chaney, W., both of Victoria Street, S.W. 1.

No. 31,454; Dec. 14, 1923.

This invention relates to the manufacture of coal gas and water gas in apparatus of the kind in which one or more horizontal retorts for carbonizing coal is or are arranged to open at one end into a vertical water gas generator.

According to this invention the generator is divided and the two halves thereof with their retorts adapted to be worked alternately. In one phase steam is admitted to the generator at one side to make water gas, and this water gas mixed with rich coal gas is entirely passed to the hydraulic main. In the second phase air instead of steam is admitted to the generator to make producer gas, the main portion of which, together with a small proportion of low-grade coal gas, is passed to the combustion chamber surrounding the retorts, while the main portion of the low-grade coal gas together with a small portion of the producer gas passes to the hydraulic main either direct or through the horizontal retorts; the relative volumes of mixed gases passing to the combustion chamber and to the hydraulic main respectively in this phase being regulated by the pull of the chimney. The other generator and set of retorts are meanwhile working in the first phase. In the combustion chamber the gas meets the secondary air, then passes round the horizontal retorts, down to the bottom of the setting, round the water gas generator, thence to the recuperator, and on to the chimney; while the water gas on the other side either

goes through the horizontal retorts to the ascension pipes thereof, or direct to separate ascension pipes. In order to increase, if necessary, the temperature of the generator which is making water gas, a portion of the producer gas from the other generator, instead of entering the combustion chamber, may be passed into flues at the side of the generator, which convey it to other flues surrounding the bottom of the water gas generator, where a separate supply of secondary air is admitted for combustion.

The preliminary heating of the setting is obtained by means of gases from an outside source—say, from the adjoining bench of retorts, or from a separate water gas plant, so that the setting will not require a producer furnace for continuously heating the retorts with carbon monoxide; and after the setting is heated, no separate blow gases are used, heat being maintained by the combustion of the gas from the generator with a small proportion of coal gas as aforesaid. Inspection doors are arranged in the outer wall of the setting opposite each of the open ends of the retorts. The primary air and steam are both preheated before entering the generator.

Testing Pipe Joints.—No. 229,048.

Ross, D., and Weiser, R. F., both of Newport, and The British Mannesmann Tube Co., Ltd., of Queen Victoria Street, E.C. 4.

No. 32,110; Dec. 21, 1923.

This invention for testing joints in a pipe line relates to apparatus which comprises an expansible circular casing carrying an india-rubber or other resilient band or ring having lateral lips or projections forming in conjunction with the inner face of the piping a closed annular chamber in communication with a pressure gauge, means for expanding the expansible casing so as to force the resilient lips against the inner face to render the chamber fluid-tight, and means for admitting fluid under pressure into the chamber for the purpose of ascertaining from the pressure gauge whether or not there is leakage through the pipe joint.

According to the invention, the expansible circular casing consists of a split ring whose two ends overlap or are tongued; and means are provided for forcing the two ends apart to expand the casing.

The two end portions are provided each with a lug, and alternative devices for expanding the ring are: (1) An eccentric mounted on one of the lugs and adapted to be operated to bear against a part of the other lug and thereby force the two lugs on the end portions of the ring further apart. (2) A hydraulic cylinder and ram, in valved connection with a source of fluid pressure and carried by one of the lugs, the outer end of the ram being pivotally or flexibly connected with the other lug, so that when the ram moves outwardly in respect to its cylinder the lugs will be forced further apart. (3) A right and left hand screw bolt, whose ends are connected respectively with the two lugs, and means for turning the screw bolt in a manner to force the lugs further apart.

Retort Discharger.—No. 229,378.

Drakes Limited and Drake, J. W., both of Halifax.

No. 29,111; Nov. 19, 1923.

This invention relates to the well-known type of pusher discharger. The patentees' original invention, which is now modified, was specified in No. 2553 of 1908 [see "Journal," Vol. 104, p. 212].

According to the present invention, each side of the sectional push bar is formed of two series of links, and the propelling wheel for same has radial projections (which have their driving edges in the form of the teeth of spur wheels), and these projections are made to take between each pair of the two series of links which form the side bars, their positions on the peripheral face of the wheel being arranged for this purpose.

Another feature of the invention is the provision of detachable shoes for the links, which are subject to wear at the parts which slide over the retort surface.

Gas Governors.—No. 229,419.

Simpson, J. F., of Scunthorpe, and Peebles, W. C., of Bonnington.

No. 30,335; Dec. 3, 1923.

The invention relates to station governors, and has for its object to provide means for maintaining, so far as is possible, constant pressure at the points of use under varying demand conditions.

We reproduce a sectional side elevation of one form of the governor according to the invention. The bell A of a well-known type of station governor has a spindle B carrying the usual double-beat valves C, D, which, as usual, control the flow of gas through the valve apertures E, F. In order to isolate the bell A from pressure which surrounds the valves, a small inner bell G is arranged around the spindle B.

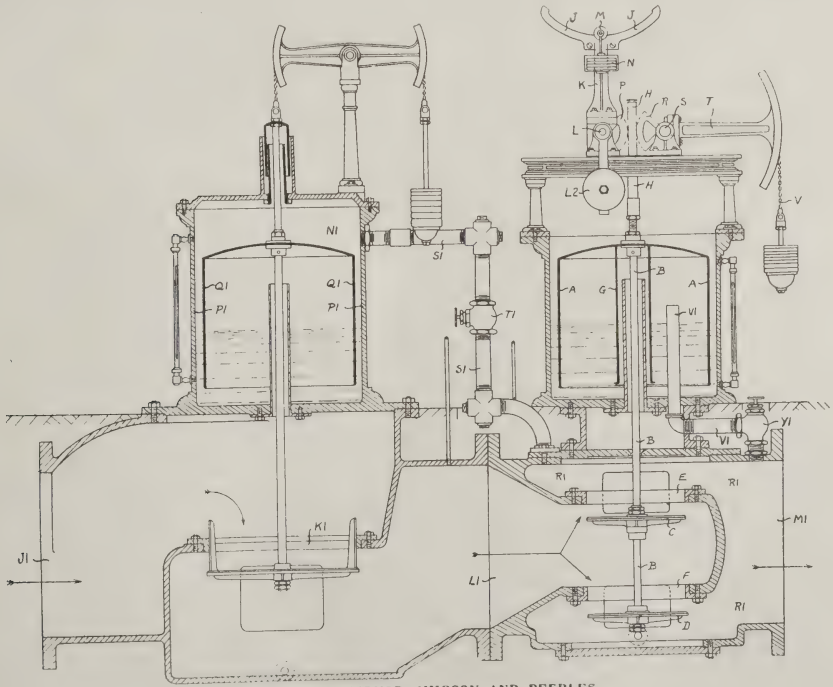
From the bell spindle B there extends upwards and through the bell-casing a toothed rack H; and to this there is operatively connected the weight-control mechanism. This mechanism consists of a curved track J carried on a lever K fixed upon a horizontal spindle L. The lever extends below the spindle, and on it is carried a weight L^2 counterbalancing lever and track. Upon the track runs a trolley M carrying upon a hanger a series of weights N by the removal or addition of one or more of which the pressure of operation can be rapidly adjusted. The lever and track are operatively connected by a tooth quadrant P fast on the spindle L and engaging the rack H with the bell A.

The bell A and its parts are partly counterpoised in the usual manner by a second toothed quadrant R engaging the rack H (which is toothed on two faces). This quadrant R is fast on a spindle S which has also fast on it the usual lever T with its quadrant and dependant chain-and-weight device V.

The effective area past the valve apertures E, F, may be varied by "hit-and-miss" or other devices, which are described and illustrated in the specification and are claimed as combined with the general arrangement.

Placed in series with and before the automatic governor is a differential governor of well-known type of which further description is unnecessary. Gas enters by its inlet J^1 and passes through valve K^1 to the inlet L^1 of the automatic governor, and thence by way of its valves to the outlet M^1 of that governor. The space N^1 within the closed and sealed casing P^1 of the bell Q^1 of this differential governor, is, however, connected with the space R^1 on the delivery side by a pipe S^1 in which is a valve T^1 adapted for fine adjustment and small areas.

The space beneath the bell A of the automatic governor is connected by a pipe V^1 with the outlet pressure by way of a needle valve V^1. Two needle valves in parallel may be provided; a small one for that



A STATION GOVERNOR—SIMPSON AND PEEBLES.

very fine adjustment required when the combination is used, and a larger one for employing the governor as an ordinary static governor. To this end the needle valves Y^1 may also be provided with pointers and dials for indicating their positions.

Control of Water Gas and Other Cyclical Processes. No. 229,399.

Humphreys & Glasgow, Ltd., and Stelfox, J. C., both of Victoria Street, S.W. 1.

No. 29,503; Nov. 22, 1923.

This invention relates to very complete automatic control of water gas plant, &c. The arrangement is described in detail with reference to 15 drawings, and there are 19 claims; so we cannot do more than indicate the scope of the patent by extracts from the introduction.

The patentees say that it is a comparatively simple matter to arrange for the movement of the operating valves by means of hydraulic or other power, and it is assumed that such power is continuously available. The problem is, however, complicated by the fact that not only must the routine opening and closing of the various operating valves be effected in proper time and sequence, but efficient operating conditions must be maintained in the generator, and (for carburetted gas) in the fixing chambers, and (with waste-heat boilers) in the production of the steam, notwithstanding the variations in the quality and character of the solid and fluid gas-making materials, and of the gas to be produced. Above all, there must be no danger of explosion.

To overcome the dangers and disabilities attaching to all previous attempts to operate water-gas plant mechanically, the present invention not only ensures automatic change in accordance with the predetermined cycle of operation, but also repuires that the various valves actually respond to the call of the mechanism automatically directing the operation of the plant, which mechanism may be referred to as the "automatic operator." Thus, if a valve sticks or for any cause does not sufficiently complete its proper movement, the cycle is automatically stopped, so that no succeeding valve can move when any valve has failed to function—thus eliminating the danger of explosion which would otherwise exist. Coincident with the stoppage of the cycle, the supervisor is automatically notified of the stoppage and just what valve has failed, so that the trouble may be promptly corrected without danger or delay in locating it.

Furthermore, in case any valve fails to perform its movement at the proper speed, the cycle is likewise automatically stopped, and the stoppage notified—thus preventing losses and troubles otherwise occasioned by sluggish movement of any valve.

Moreover, in case of the failure of any valve to function properly, the invention also includes the automatic and safe shutting-down of the plant (except the delinquent valve, if otherwise stuck) and notification to the supervisor of such shutting-down and of just which valve has failed. Failure of the power driving the automatic operator may also cause shutting down the plant automatically and safely, notifying the supervisor.

In addition, the timing of movement of any or all of the operating valves may be immediately modified; and any or all of the following operations may be instantly suspended or resumed (or hand controlled), as may be necessary from time to time to attain the most efficient conditions for making water gas (either blue or carburetted to any desired quality), without interference with the inherent safety of the apparatus—namely:

(*a*) Down-running (in accordance with clinkering necessities).
(*b*) Secondary combustion (to govern temperatures in fixing chambers).
(*c*) Secondary combustion (of surplus CO for steam production).
(*d*) Oil supply (in accordance with quality of gas desired).

The invention provides for automatic charging of fuel to the generator, which may be likewise regulated or suspended or hand-controlled at will without interference with the inherent safety of the invention; and also for instant substitution at will of hand-control (with the actual response of each valve completely indicated and preferably in interlocked sequence) for automatic operation of the plant.

Gas Meters.—No. 229,512.

Kirkewhite Engineering Co., Ltd., and Goldspink, G. E., both of Nottingham.

No. 6680; March 15, 1924.

This invention relates to the means for attaching gas-meter diaphragms to the rim. A binding wire is used which has turned ends engaging holes in arms which are mounted on a hinge pin fixed to the rim. These arms are connected to each other by a screw or bolt which is adapted to draw the arms together and tighten up the binding wire.

As a combination with the above, the patentees claim a post in the diaphragm plate provided with a sleeve at its outer end at right-angles to the main part, and a "flag" or arm having its end jointed to the post by means of a joint pin passing through the sleeve and bearings on the flag or arm, so that the latter can be disconnected by removing the joint pin.

PARLIAMENTARY INTELLIGENCE.

HOUSE OF LORDS.

Progress of Bills.

Bills read the third time, passed, and sent to the Commons: Horley District Gas Company (Electricity Supply) and the Rochdale Corporation.

Hoylake and West Kirby Urban District Council Bill: Reported from the Select Committee, with amendments.

A Select Committee has been appointed to consider the Mansfield Corporation Bill, and will meet on Wednesday, May 13.

HOUSE OF COMMONS.

Progress of Bills.

Bills reported, with amendments: Gas Light and Coke Company, Stockton-on-Tees Corporation.

Bills read the first time, and referred to the Examiners: Horley District Gas Company (Electricity Supply), and Rochdale Corporation.

Gas Regulation Act.

Copies were presented of drafts of Special Orders proposed to be made by the Board of Trade under section 10 of the Act, on the application of the East Grinstead Gas and Water Company and the Slough Gas and Coke Company.

Bye-Products.

Colonel Crookshank asked the Secretary for Mines whether he could furnish any information as to the possible value of the oil and other important bye-products obtainable from coal; and if there was any reasonable prospect of their being successfully extracted, in view of the waste represented in this direction.

Colonel Lane-Fox said that, if the question related to processes of low-temperature carbonization, he would draw attention to the reply on Feb. 10. The value of these processes obviously depended upon the extent to which they could be operated commercially at a profit; and the Government would spare no efforts to assist in developing them and endeavouring to make them a commercial success.

Motor Spirit and Benzole.

Mr. D. Grenfell (for Mr. George Hall) asked the President of the Board of Trade whether he could give the total number of gallons of motor spirit, including benzole, used in the British Isles in 1913 and 1924; and the total number of gallons of home-produced benzole used as motor spirit in 1913 and 1924 respectively?

Mr. A. M. Samuel, in reply, said that precise information as to the consumption of motor spirit, including benzole, could not be furnished. From such particulars as were available, it might, however, be estimated that the consumption in 1913 was approximately 120,000,000 gallons, and in 1924 approximately 500,000,000 gallons. The information available did not enable a similar comparison to be made of the consumption of home-produced benzole as motor spirit.

HORLEY DISTRICT GAS (ELECTRICITY SUPPLY) BILL.

(*Concluded from p.* 66.)

Tuesday, March 24.

Mr. Tyldesley Jones, continuing his address to the Committee, said that nothing had been more striking than the way the scheme of the Gas Company had altered since its original conception. It had been said by Sir Harry Courthope-Munroe that the utilization of waste heat was the keynote; but when Mr. Seabrook had given evidence, they had found that it was nothing of the sort, because it was not at first the intention to utilize waste heat. The whole Bill was an attempt to put a restraining hand upon the activities of any electrical undertaking which might be introduced into this district. The site of the generating station had been altered since the original conception, and it was now proposed to erect the station on the gas-works site, which, he suggested, was already overcrowded. Even if the Bill were passed, the Gas Company would have to get the consent of the Electricity Commissioners to the erection of the generating station; and before the Commissioners gave their consent, they would require plans. The real matter the Committee had to consider was under which scheme would the consumer benefit most. The Gas Company proposed to charge 10d. per unit for electricity, and this was the maximum price asked for by the Electricity Company, so that there was nothing between them as to price. But, whereas the Electricity Company had a strong incentive to effect economies and reduce the price, in order to increase business, the Gas Company had not, because increases in the sale of electricity would to some extent be at the expense of gas. The gas undertaking was operated under the sliding-scale, by which increased dividends could only be paid if the price of gas were reduced; but no such sliding-scale was attached to the electricity undertaking. If the Gas Company kept-up the price of electricity, they would get more money from the electricity consumers, and, at the same time, would place gas in a more advantageous position to compete with it. With regard to the Gas Company's estimates, he said that the estimated cost of generation in the first year was £373. Of this, £300 represented maintenance and repair of plant, and wages, and £73 represented the cost of fuel for generating one-quarter of the electricity produced. He suggested that the cost of the fuel would be another three times as much, so that £220 should be added; and this would make the total generating costs £593. Also, nothing had been credited to the gas-works for the value of the waste heat which would be used, and nothing had been allowed for insurance, which latter was a big item. As to the

statement that 21 gas companies had been granted electricity powers, he said that many of them had not supplied electricity until some years after they had received powers. Even the Yorktown and Blackwater Gas and Electricity Company had not supplied electricity until twelve years after receiving powers. He suggested that the reason why these companies had at last given a supply was that, if they had not done so, their powers would have been revoked, and they would have had to face competition. A suggestion had been made to obtain a bulk supply at Horley from the Southern Railway Company; and when the railway was electrified, as it would be, no doubt the proper thing would be to get a supply in bulk. Then the advantages of generation of electricity by the utilization of waste heat would not exist. The very fact of the opportunity of obtaining a bulk supply later would be a good argument for the Gas Company to do nothing.

Mr. *R. L. Norris* (Chairman of the Electricity Company, and a member of the Reigate Rural District Council) gave evidence as to the need for electricity in Horley, and the formation of the Company by the local residents. £10,400 had been subscribed; and if the Electricity Company's scheme were not proceeded with, their money would be thrown away.

Sir Harry Courthope-Munroe, cross-examining, pointed out that it was equally true that, if the Bill were refused, the Gas Company's expenditure would be wasted.

Evidence was also given as to the need for a supply, and as to the formation of the Electricity Company, by Mr. J. H. Robinson, Mr. C. G. Selfe, and Mr. A. C. Rowson—all Directors of the new Company, and residents of Horley.

Mr. *C. R. St. John* (Consulting Engineer, Westminster) said he was invited to attend a Committee meeting in Horley on Feb. 12, 1923, and was asked to advise generally with regard to the electricity supply in Horley and the neighbourhood. The scheme which had been prepared previously by another engineer had been rejected, because he had reported that it was on far too small a scale for Horley; and he was asked to submit an alternative one. After surveying the district, he had concluded that alternating current was the proper method of supply. It was desirable to obtain a bulk supply if possible, and his negotiations had been delayed as the result of his attempts to obtain it; but these attempts had not been successful. When the railway was electrified, places such as Horley would be able to get a bulk supply from the Southern Railway Company, and his plan was an endeavour to tide-over the period before that. His scheme consisted of a generating plant driven by an oil engine on a site near the railway station, and the distribution system was 415 to 240 volt, 3-phase, 4-wire, 50-cycle. His report was adopted by the Committee, and the decision was then made to form the Company. They had decided to proceed with the Company from the end of July, 1924. He then handed-in tables showing the estimated results and expenditure involved by his scheme. In the first year he estimated 120 consumers, in the second year 220, and in the third year 300; and the total estimated revenues for those years, including units sold, meter rents, wiring sales, and hire service, were £2200, £3900, and £5600 respectively. In the first year there would be a deficit of £335, in the second year all charges would be met, and in the third year a profit would be made for the first time. His estimated gross profit for that year was £1250. With regard to capital expenditure, this was estimated at £12,800 for the first year, £6800 for the second, and £2400 for the third. As to the charges for current, consumers would have the option of taking lighting at 10d. per unit, and power for heating and cooking at 2½d., or of paying a fixed quarterly sum for the installation, based upon the floor space of the house, *plus* 1½d. per unit for all current used for any purpose. The latter system would enable duplicate wiring to be avoided. This system had worked-out successfully in other undertakings of which he knew. It was proposed that the Company should have power to undertake the wiring of houses; and he regarded these powers as necessary where it was desired to develop a district rapidly. He knew of no undertaking which had made a profit in the first year. He was quite satisfied that the Company could give a satisfactory supply for as long as the supply was generated locally, and was so favourably impressed with the proposition that he had made an offer to subscribe one-half of the capital, or, if less than £10,000 were subscribed, to find £5000. He was also prepared to take his consulting fees to a large extent in the form of shares.

Cross-examined by Mr. Abady, he said he had been connected with a scheme for electric supply in the Wirral Rural District, where the Electricity Commissioners had held an inquiry to consider competitive schemes; and he agreed that this was an example of the fact that, where there were competitive schemes, it was usual to hold an inquiry. Mr. Abady also cross-examined with regard to an estimate of sales in the Company's prospectus, the estimate in witness's report put before the Electricity Commissioners, and the estimate now put before the Committee, to show that they all disagreed. Counsel suggested that there was practically no evidence from existing undertakings to support witness's optimism that he would sell 225,000 units in the third year, as he had estimated.

Mr. *John C. Dalton* (Ministry of Transport) gave evidence with regard to the Order made by the Electricity Commissioners in favour of the Electricity Company. Asked by Sir Harry Courthope-Munroe why the Order had been promulgated without the Gas Company being heard, he said that the Commissioners had had to consider the Electricity Company's scheme alone because the Gas Company had merely said that the Directors had had under consideration the question of obtaining powers to supply electricity, and had submitted no scheme of their own.

Mr. *M. J. Collins* (representing the Electricity Commissioners) said that the only application before the Commissioners was the application of the Electricity Company. The Gas Company had raised objection, but had given no reasons beyond the fact that they were competitors of the scheme. Objections had been raised by others with regard to the site for the generating station; and an inspector visited Horley to inspect the site, and had given the objectors an opportunity of being heard. He believed one of the objectors was the Chairman of the Gas Company, and he had had a notice that the inquiry was being held, so that the Gas Company must have known.

Sir Harry Courthope-Munroe stated that the Commissioners had been informed that the Gas Company had definitely decided to apply for powers

Witness remarked that the present position was probably unique, in that there was one application before the Commissioners and another before Parliament, for supplying the same area.

Sir Harry Courthope-Munroe suggested that, had the matter been before the Board of Trade, who dealt with these matters before the passing of the Electricity (Supply) Act, 1919, instead of the Electricity Commissioners, they would not have made the Order, but would have shelved it until they had ascertained what was the intention of Parliament.

Witness was of opinion that the Board of Trade would have acted in the same way as had the Commissioners.

Sir Harry Courthope-Munroe, in reply to the Chairman, said that the Gas Company had had no notice of the inquiry at Horley. This had nothing to do with the scheme, and it was not an inquiry under the Electricity (Supply) Act; it simply had to do with the site.

Mr. *W. Sidgwick* (Messrs. Rees & Freres, Parliamentary Agents) said there were cases in which a department had done what the Electricity Commissioners had done in this case—namely, dealt with the Special Order without waiting for the decision of Parliament on the Bill. The Order, if sanctioned by the Minister of Transport, would have to be confirmed by Parliament, so that the latter would have an opportunity of considering the two together. The Electricity Commissioners could only consider the scheme before them.

Sir Harry Courthope-Munroe said it seemed that, though the Gas Company had lodged an objection to the Electricity Company's Order, they had not stated that they wished to be heard upon it, notwithstanding that the Order was in competition with the Gas Company's Bill. Surely it was not thought that the Gas Company did not wish to be heard.

In his final speech to the Committee, Sir Harry said that the suggestion made by the Electricity Company, that the Gas Company made their application in order to restrain electrical development, was ridiculous. Development in the realm of electricity was a post-war matter. Mr. Randall had joined the Board of the Company in 1922, holding very strong views on the desirability of joining-up electricity and gas supply, and at that time had no knowledge of the first scheme prepared by the Electricity Company. He had heard about it afterwards, and this had accentuated his view that the time was ripe for the Gas Company to apply for powers. The Gas Company were first in the field, and had stolen nobody's case. It had been said that the most important matter was the interest of the consumers, and he was absolutely in agreement with that view; it was the test upon which the Bill should stand or fall. It was beyond dispute that the existing Gas Company, if the Committee thought they honestly intended to give the supply, were infinitely better fitted to carry it out than the new Company. The Electricity Company had been able to call only one engineer, whereas the Gas Company had the support of eminent engineers in Mr. Broadberry, Mr. Gill, and Mr. Seabrook. The capital to be raised by the Gas Company for the electricity undertaking would have to be sold by auction, and the premiums obtained as a result would be used for the purposes of the electricity undertaking without any charge upon it. He quoted at length from the evidence of witnesses on behalf of the Gas Company, and asked the Committee, having regard to the nature of that evidence, to allow the Bill to proceed.

After the Committee had consulted in private,

The Chairman asked how long it would take the Gas Company to complete the undertaking, in order that a supply of electricity could be given.

Sir Harry Courthope-Munroe said that it would take twelve months from the date of Royal Assent to the Bill.

The Chairman said that in that case the Committee found the preamble of the Bill proved, but that it be an obligation upon the Gas Company to complete the works so that the supply could be given in the compulsory area in twelve months from the date of Royal Assent.

The Gas Engineer advising the Electricity Company was Mr. Arthur Valon (Messrs. W. A. Valon & Son, Civil Engineers, Westminster), but he was not called upon to give evidence.

STOCKTON-ON-TEES CORPORATION BILL.

This Bill was considered by the Unopposed Committee of the House of Commons, presided over by Mr. James F. Hope (Chairman of Ways and Means), on Wednesday, April 1, and was ordered to be reported for third reading. The purposes of the Bill are to enable the Corporation to purchase by agreement the undertaking of the Haverton Hill-on-Tees Gas Company, Ltd., which Company supply gas in part of the Urban District of Billingham, adjacent to the existing gas supply limits of the Corporation; to extend the limits of supply of the Corporation to include so much of the Urban District of Billingham as is not already within their limits, and the township of Cowper Bewley; and to confer further powers upon the Corporation with regard to the supply of electricity and consolidation of rates (see "Journal" for Jan. 14, p. 83).

Mr. H. Gibbon Pritchard (Messrs. Sharpe, Pritchard & Co., Parliamentary Agents) said that the purchase had been undertaken with the agreement of the Billingham Urban District Council. In reply to the Chairman, he said that the whole of the area of the Company was outside the Borough of Stockton, but about half of the Urban District of Billingham was at present within the limits of supply of the Stockton Corporation.

Mr. *Arthur Valon* (Messrs. W A. Valon & Son, Civil Engineers, Westminster), who advised the Corporation in connection with the purchase, said he had examined the Haverton Hill Company's undertaking, and was satisfied that the price proposed to be paid for it—namely, £24,155—was a favourable one for the Corporation. He had made a valuation of what it would cost to replace the plant (works, mains, meters, and stoves) at the present time, and his figure was £33,286.

A series of reports on the Bill from the Board of Trade, Home Office, and Ministries of Health and Transport was then dealt with.

One suggestion in the Board of Trade report, relating to the extension of the gas limits of the Corporation, was that, if any part

of the extended limits of supply was at present supplied with gas by a non-statutory undertaking, the Corporation should be restricted from supplying gas in such area until they should have come to an agreement with the non-statutory undertaking. Mr. Pritchard said that the only recognized company really supplying gas was the Haverton Hill Company. He understood, however, that there were one or two private streets in the new area of supply which were now supplied by Messrs. Dorman Long & Co., Ltd. The Corporation did not propose to supply there unless this firm wished them to do so, but there was a provision in the Bill enabling the Corporation to enter into an agreement with the firm, or any other persons who happened to be supplying gas within the Corporation's limits, to purchase the mains and pipes, and the goodwill attaching to the business, or to pay compensation to those persons for giving up their rights to supply. In reply to Sir Ernest Moon, K.C. (a member of the Committee), Mr. Pritchard said that Messrs. Dorman Long & Co. had not raised any objection. They were well acquainted with Parliamentary procedure, and, therefore, he assumed they were satisfied with the Corporation's proposals.

Another clause to which reference was made in the Board of Trade report was that relieving the Corporation from the obligation to supply gas for other than lighting or domestic purposes from any main the capacity of which was insufficient; and the report pointed to the negotiations now taking place between the National Gas Council and the railway companies, with a view to arriving at an agreed form of clause. The form of the clause inserted in the present Bill, said Mr. Pritchard, was that which the railway companies had asked for in the Barnsley Order and the Chesterfield Act two years ago, but the railway companies had since discovered a further objection to the clause. In view of the negotiations referred to above, the Corporation had given an undertaking to the London and North Eastern Railway Company that they would accept any clause which the railway companies and the National Gas Council might agree upon. In the meantime, he asked the Committee to allow the clause already in the Bill to remain; and the Railway Company raised no objection to this. Asked by the Chairman when the new clause was likely to be settled, he said he could not hazard a statement on this, though he had seen what he believed was practically the final form of the clause. The Corporation had, however, given the Railway Company an undertaking that, should the matter not be settled by the time it was necessary to petition against the Bill, if they wished to, in the other House, the Corporation would raise no objection to the Railway Company's depositing a petition.

The Committee agreed to this suggestion.

Another clause to which reference was made in the Board of Trade Report was to enable the Corporation to refuse to supply gas or electricity to any person whose payments for the supply of either were in arrear, whether such payments were due to the Corporation in respect of a supply to the premises in respect of which such supply was demanded, or in respect of other premises. The Board of Trade report stated that the clause was much wider in its scope than clause 32 of the House of Lords Model Bill, and would enable the Corporation to cut off the supply of gas and electricity in the event of payments being in arrear in respect of either commodity supplied to any premises, occupied by the same consumer, irrespective of the circumstances under which, and the period for which, the payments might be in arrear.

Mr. Pritchard said that the Corporation supplied both gas and electricity, and wanted to deal with the consumer who (say) was taking a supply of electricity and did not pay for it, and who, when back payments were demanded, said he would not take any more electricity but would have a supply of gas. If that consumer were prepared to enter into a contract with the Corporation for a supply of gas, the Corporation were at present bound to enter into that contract, and to expend the capital necessary to enable the supply to be given. There was also a report from the Home Office which raised this point, and which stated that similar provisions were disallowed in the Chesterfield and the Swanage Gas and Electricity Bills of 1923. The matter had been threshed out at great length recently by a Committee of the House of Lords (presided over by the Earl of Clarendon) in the Hoylake and West Kirby Urban District Council Bill (see "Journal" for March 25, p. 749). The Director of Gas Administration at the Board of Trade had laid his objections before that Committee, but the Committee had unanimously granted the clause, and had granted it again in the Nottingham Corporation Bill.

The Chairman asked the effect of the model clause.

Mr. Pritchard replied that it provided that, if a consumer of gas had not paid his accounts, then the gas authority might refuse to supply him with gas. It did not meet the case of the consumer who would not pay his bill for one commodity, and demanded a supply of the other.

Sir Ernest Moon, K.C., pointed to a statement in the Home Office report that Committees had generally taken the view that the powers of one undertaking should not be used as a lever to obtain payment of money due in respect of the other.

Mr. Pritchard, in reply to the Chairman, said the consumer was safeguarded, because, if the Corporation cut off the supply of either gas or electricity, and it was found that there was good reason why the consumer had not paid his bill, then the Corporation were liable for heavy damages.

The Chairman announced that the Committee did not raise objection to the insertion of the clause.

A stand-by clause in the Bill, which the Board of Trade suggested should be amended to follow as far as possible the provisions of the Electricity (Supply) Act, 1922, with a view to uniformity, was withdrawn by the promoters.

With regard to a clause giving the Corporation power to specify the size and material of the pipes and fittings between the main and the consumer's meter, the Board of Trade suggested that there should be substituted a clause usually inserted in special Orders in accordance with the recommendation of a conference at the Board of Trade on Feb. 8, 1923, at which representatives of local authorities and of gas undertakings were present. Mr. Pritchard said that the clause in the Bill at present was taken from the House of Lords Model Bill, and only dealt with pipes and fittings between the main and the consumer's meter, which was all the Corporation desired to have power to deal with. The clause suggested by the Board of Trade would enable the Corporation to deal with pipes and fittings throughout the consumer's premises, but, to do this, they had to advertise in the "London Gazette" and in two local newspapers; they were subject to a reference to an independent gas engineer; and, if he thought fit, a local inquiry would be held, before the Corporation could do anything under the clause. The Corporation were content with the lesser power, in order to avoid that trouble. Incidentally, the consumers in Stockton had had no notice of a suggestion that the Corporation should be entitled to deal with the fittings in their houses, and it would scarcely be fair to the consumers for the Corporation to take this power.

The Committee agreed to the Corporation's proposal.

There was some discussion with regard to the suggestion in the report of the Ministry of Health that the period for repayment of the £24,155 to be borrowed for purchasing the Haverton Hill undertaking (40 years was inserted in the Bill) was too long.

Mr. Pritchard suggested that that period was not too long. In the case of the Hoylake and West Kirby Urban District Council Bill the period asked for in respect of money borrowed for purchasing an undertaking was 60 years, and the Ministry of Health had suggested 40 years. The Stockton Corporation asked for 40 years, and the Ministry suggested 35, and it was to be inferred that the Ministry always suggested a shorter period than that asked for by promoters. In the present case the Corporation had been very moderate. The undertaking to be purchased had a large future before it, and there were big prospective profits to be earned. Thus, the future ratepayer would have more revenue than the present ratepayer for meeting the repayments of sinking fund and interest on the loan, and it seemed a little hard that the present ratepayer should be burdened, as he would be if the period of repayment were reduced, when he would not have the benefit of the revenue from the undertaking.

The Chairman asked what the profits on the Haverton Hill undertaking were at present

Mr. *Valon* said the profit in 1924 was £2084, and in 1923, £2209.

Mr. Pritchard pointed out that the Corporation had agreed to reduce the price of gas.

Mr. *Valon*, in reply to Sir Ernest Moon, said the present price in the Haverton Hill Company's area was equivalent to 13·5d. per therm; after transfer the price would be 9·2d. per therm—a drop of over 4d. Asked if the plant were up-to-date, he said that the Corporation would manufacture gas at Stockton, but would use the gasholders, mains, meters, and small plant of the Haverton Hill Company. This plant was quite good. Many mains had been laid recently, and they were larger, on the whole, than one would expect to find in an undertaking of the size.

The Committee agreed to allow a period of 40 years.

As to the period of repayment of the loan necessary to defray the costs and expenses incidental to the transfer of the undertaking, for which 40 years was asked originally, the Ministry of Health suggested a shorter period. Mr. Pritchard said that he understood there was very little physical work to be carried out, except for connecting up mains, and the Corporation were prepared to accept 20 years.

Mr. Thomas Downey (Town Clerk of Stockton) proved the preamble of the Bill, which, as stated, was ordered to be reported.

BEXHILL CORPORATION BILL.

One of the objects of this Bill is to empower the Bexhill Corporation to acquire compulsorily, or by agreement, the undertaking of the Bexhill Gas and Water Company (see "Journal" for Jan. 14, p. 83). There was a petition deposited against the Bill by the Company, but when it reached a Committee of the House of Lords, presided over by the Earl of Clarendon, on Wednesday, March 25, Sir Lynden Macassey, K.C., (for the Corporation) said he was very glad indeed to be able to say that, as the result of negotiations which had taken place between the Corporation and the Company, agreement had been arrived at. Provision would be made by that settlement for the transfer of the undertaking to the Corporation, and the main terms of the agreement had been negotiated. He suggested that the Committee should allow that part of the Bill dealing with the transfer to proceed in its original form, and, when the Bill reached the Lord Chairman, and the agreement was finally reduced to formal language, the promoters would ask the Lord Chairman to include it in the Bill in substitution for the compulsory clauses. The Lord Chairman would be asked not to report the Bill to the House until that had been done.

Mr. Jacques Abady (for the Bexhill Gas and Water Company) agreed to this course.

ROCHDALE CORPORATION BILL.

This Bill has been under consideration by a Committee of the House of Lords, presided over by the Marquess of Bath, and has been ordered to be reported for third reading.

The clauses relating to the gas undertaking of the Corporation remain as indicated in the "Journal" for Jan. 28, p. 210, with the exception of one clause. This provided that if, in the opinion of the Corporation, any waste of gas or injury or risk of injury to person or property was caused, or likely to be caused, by a defective fitting, the Corporation could carry out the necessary repairs, at the expense of the consumer or house owner. The terms of the clause (it was set out fully in the "Journal") were considered by the Board of Trade to be too wide; and the following clause, which gives the Corporation power to compel repairs only in case of danger, has been substituted:

> If the Corporation shall at any time serve notice upon any consumer to the effect that an officer or servant of the Corporation has reported, after inspection of any internal piping or gas-consuming appliance or fitting on such consumer's premises, that he is of opinion that any such internal piping or gas-consuming appliance or fitting is in such a condition as to be dangerous to the occupiers of the premises, such consumer shall forthwith

carry out such works as may be necessary to remove the cause of danger. If the consumer shall fail forthwith to carry out such works as aforesaid, the Corporation may stop the gas from entering the premises of such consumer by cutting-off the service pipe or by such other means as the Corporation shall think fit. Any expenses incurred by the Corporation in cutting-off the gas from such premises may be recovered by the Corporation summarily as a civil debt.

WOLVERHAMPTON CORPORATION BILL.

One of the objects of this Bill (which was considered by the Local Legislation Committee of the House of Commons recently) was to authorize the Corporation to carry out various street works. A petition was deposited against it by the Wolverhampton Gas Company, with a view to securing protection for their apparatus; but opposition was withdrawn on the insertion of a protective clause. This clause provides that before commencing any authorized work in any street or road within 10 ft. of any of the Company's apparatus, the Corporation are to give fourteen days' notice to the Company, and to deliver plans of the work for reasonable approval. If no objection is raised by the Company within fourteen days, they shall be deemed to have approved. The Corporation are also to give the Company any further information reasonably required. If it appears to the Company that the execution of the proposed works would interfere with or endanger their apparatus, or unreasonably interfere with access thereto, or impede the supply of gas, they may, within the fourteen days, give the Corporation notice to alter the position of such apparatus as may be reasonably necessary, any difference as to the reasonable necessity of such alteration or the manner of carrying it out to be settled by arbitration. Such alterations are to be carried out by, and at the expense of, the Corporation, with as little detriment and inconvenience to the Company as the circumstances will admit, and to the reasonable satisfaction of the Engineer to the Company.

The Corporation are not to remove or displace any apparatus, or do anything to endanger it, impede the passage of gas through it, or interfere with access thereto without the consent of the Company, or in any other manner than the Company shall approve, until they have substituted other apparatus, at their own expense, and to the reasonable satisfaction of the Engineer of the Company.

Whenever, by reason of the exercise of the powers conferred on the Corporation, any apparatus other than that for which new apparatus has been substituted is rendered derelict or unnecessary, the Corporation are to pay the Company the agreed value of that apparatus, or the value as determined by arbitration; and the apparatus is to become the property of the Corporation. The Corporation are also to pay the reasonable cost of cutting-off that apparatus from other apparatus.

The Corporation are to make good any damage done to apparatus, or to make full compensation to the Company for any loss, damage, costs, or expenses which the latter may sustain. The Company may carry out alterations if they so desire, at the expense of the Corporation, if they give seven days' notice.

LEGAL INTELLIGENCE.

AN OXYGEN DISPUTE.

Judgment.

On Monday, Mr. Justice Romer delivered judgment in the action brought by the British Oxygen Company, Ltd. [See *ante*, p. 67.]

His Lordship said the plaintiffs were manufacturers and sellers of oxygen, and the defendants were manufacturers and sellers of plant capable of manufacturing oxygen gas. In December, the defendants approached Tanks & Drums, Ltd., with a view of inducing them to purchase plant by which they could manufacture oxygen for themselves, instead of purchasing it from the plaintiffs. To counteract this move, the plaintiffs offered to supply Tanks & Drums, Ltd., with oxygen at a reduced price, and stated that if the offer was not accepted by a certain date the price would be greatly increased. Unfortunately, this letter was handed by the Manager of Tanks & Drums, Ltd., to a representative of the defendants; and they caused twelve photographic copies to be made, one of which was sent to a London stockbroker for the purpose of showing what the plaintiffs were prepared to do to try to obtain customers. The plaintiffs, when they discovered the use to which the letter was being put, brought their action for an injunction, on the ground that their copyright was being infringed, and that the letter was confidential. The jurisdiction of the Courts to grant such relief was settled as long ago as the time of Lord Hardwick. It had been urged on behalf of the defendants that the letter was not a literary work; but he did not agree with this submission. He thought the plaintiffs had a copyright in the letter, and to make copies of it was an infringement of their right. A further point taken on behalf of the defendants was that no relief could be granted, as the act of the plaintiffs was against public policy and in restraint of trade. Plaintiffs were justified in endeavouring to retain their customers by offering a reduction in price so long as these customers took all their oxygen from them. It was further said that the defendants' object in doing what they did was to clear themselves, and to vindicate their character. He thought, however, it was clear that the object was not to vindicate themselves, but to attack the commercial character of the plaintiffs' Company. The act of the defendants being unlawful, he must grant an injunction restraining them from publishing, printing, circulating, or exhibiting, or causing to be published, printed, circulated, or exhibited, the letter in question, or from otherwise infringing the plaintiffs' copyright therein.

As the parties had agreed to treat the motion as the trial of the action, there would also be an order for delivery up to the plaintiffs of any copies of the photographed reproduction of the letter in the possession of the defendants; and the defendants must pay the costs.

MISCELLANEOUS NEWS.

GAS REGULATION ACT APPLICATIONS.

There have appeared in the "London Gazette" the following notices regarding applications to the Board of Trade under the Gas Regulation Act.

SPECIAL ORDERS.

Devizes Corporation.

The Corporation are applying to the Board of Trade for a Special Order to authorize them to use scheduled land for gas purposes and to purchase additional lands; to define the limits of supply; to enable them to borrow further money; to establish the thermal basis of charge; to make regulations in connection with the supply of gas; and for other purposes.

Newark Corporation.

Application is being made by the Corporation for an Order under section 10, to empower them to acquire the undertaking of the Newark Gas Company; to construct a railway siding to the works; to define the limits of supply; to borrow money; and to confer various other powers upon them in connection with the carrying-on of the undertaking.

Ormskirk and District Gas and Electricity Company.

A Special Order is being sought by the Company, to give them authority to borrow further money; to enable them to set aside sums for a capital redemption fund; and to confer general powers.

GAS REGULATION ACT ORDERS.

The Director of Gas Administration has forwarded a copy of the following further Order made by the Board of Trade under section 1 of the Gas Regulation Act.

Aberdeen Corporation.

The Order is in the usual terms, but with no price figure inserted. [March 27.]

SOUTH METROPOLITAN GAS COMPANY'S BASIC PRICE.

Suggested Revision Application by the L.C.C.

At last week's meeting of the London County Council (replying to questions by Mr. J. D. Gilbert), Mr. Cyril H. M. Jacobs (the Chairman of the Public Control Committee) stated that the Committee would submit a report to the Council concerning the notice issued by the South Metropolitan Gas Company relative to the price of gas. The report, which appeared in this week's agenda, is in the following terms.

A question was raised in the Council on March 25, 1925, regarding the recent increase from 8d. to 8¾d. a therm by the South Metropolitan Gas Company in the price of the gas supplied by them, such increase to take effect as from the date of reading the meters for the Lady Day quarter. As the matter is one of public interest we report the facts.

Successive reductions were made by the Company in question in the price charged for gas between Michaelmas, 1922, when the price stood at 11½d. a therm, and Michaelmas, 1923, when the price reached 8d. a therm. The Company attribute the necessity for the recent increase in price to the heavy fall in the receipts from bye-products, and to the increase in wages paid from the beginning of the year.

The price charged for gas is primarily dependent on the cost of production and distribution. No advantage is likely to accrue to the shareholders of the Company by reason of an increase in the price charged, since the dividend is limited by Act of Parliament. Under the South Metropolitan Gas Act, 1920, the price charged may include provision for a dividend of 5 p.ct. on the existing ordinary stock, and 6 p.ct. on any new ordinary stock which may be issued in future; but any addition to these dividends must be accompanied by a reduction of the price of gas below the "basic" price, which was fixed by the above-mentioned Act at 11d. a therm. The Act provides that, after allowing for the above authorized dividends, any "surplus profits" may be divided in the proportion of three-quarters to the consumers (in reduction of price), one-eighth to the stockholders, and one-eighth to the employee co-partners of the Company. The amount of the "surplus profits" is arrived at by calculating the sum by which the total amount payable by consumers during each year or half-year has been less than the amount which would have been payable if the gas had been charged for at the "basic" price. The sum so calculated is called the "consumers' share," and the amount of the "surplus profits" is a sum of which the "consumers' share" is three-quarters.

If the Company had paid the full dividend allowed by the provisions of the Act, the increase in price now made would involve a reduction of dividend. The actual dividends paid in recent years, however, have been considerably below those allowed by the Act. Under the Act, the Company would have been entitled to pay a dividend of 8·2 p.ct. on the ordinary stock for the year 1924; but the actual dividend paid was only 5¾ p.ct., a sum of £16,500 (equal to a further ¼ p.ct.) being allocated to the reserve fund, and £66,074 (equal to 1 p.ct. on the ordinary stock) to the co-partnership fund.

Under the Company's Act of 1920, the Council have a right, in the present session of Parliament, to ask for a revision of the "basic" price (at present 11d. a therm), and the necessary action is being taken accordingly. Any reduction in the "basic" price which may be obtained, however, will not necessarily affect the price which may be charged by the Company for gas, as this depends mainly (as explained above) on the cost of production and distribution. The effect of a reduction of the "basic" price will be to reduce the amount of the dividends which the Company would be *authorized* to pay, and the amount of the bonus which may be awarded to the employee co-partners of the Company.

NORTHAMPTON GAS ORDER.

Mr. H. C. Honey (Director of Gas Administration at the Board of Trade) inquired into the application of the Northampton Gas Light Company for a Special Order under section 10 of the Gas Regulation Act, on Monday, March 30, at the offices of the Board. The purpose of the Order is to extend the area of supply of the Company to include a large number of parishes in Northamptonshire.

Objections by the London, Midland, and Scottish Railway Company, the Grand Junction Canal Company, and the Weedon Gas Light, Coke, and Coal Company, Ltd., were met by the insertion of protection clauses; and the only objection remaining to be dealt with at the inquiry was that of the Northamptonshire County Council, who asked for protection beyond that afforded by general legislation with regard to roads and bridges, on the ground that the general legislation is out-of-date.

The Company were represented by Mr. S. E. Cash (Messrs. Vizard, Oldham, Crowder, & Cash, Parliamentary Agents); and the County Council by Mr. Parker (Messrs. Sharpe, Pritchard, & Co., Parliamentary Agents).

Mr. Cash dealt first with the clause releasing the Company from the obligation to supply gas from any main for other than lighting and domestic purposes, if the capacity of the main is insufficient. This was the subject of objection by the London, Midland, and Scottish Railway Company, who pointed out that the form of the clause is at present under discussion by the National Gas Council and the railway companies. As the Railway Company did not propose to attend the inquiry, he did not know whether they were relying upon the promoters not to insert the clause, or whether they were leaving it to the Board of Trade to decide whether to grant the clause or to let the matter stand over for the time being.

Mr. Honey said he had received a letter from the Railway Company to the effect that, as the promoters had agreed to wait until the clause had been settled between the National Gas Council and the railway companies, and then consider whether the clause should be inserted, it was not deemed necessary for them to be present.

Mr. Cash said he would prefer to drop the clause altogether, rather than wait for the agreement to be reached, because he gathered it would not be decided for some time.

Mr. Honey said he hoped that was not the case, because the matter had gone on long enough.

Mr. Cash, dealing with the objection of the County Council, said it was stated that the existing Acts and Orders of the Gas Company incorporated the provisions of the Gas-Works Clauses Acts, 1847 and 1871; but the provisions of those Acts, and of the existing Acts and Orders, were not sufficient for the protection of the County Council. At the time the Gas-Works Clauses Act, 1847, became law, the circumstances with regard to roads and traffic were very different from the circumstances prevailing to-day; and the provisions contained in the existing Acts and Orders were not suitable to meet the requirements of present-day traffic. It was submitted, therefore, that further provision should be made for the protection of the County Council in relation to main roads and county bridges and other works, both with regard to the existing area of supply of the Company (so far as it was within the county of Northampton) and the new area. Among other things, provision should be made for requiring works of the Company to be laid in suitable positions in roads and across bridges; for enlarging the period of notice under section 8 of the Gas-Works Clauses Act, 1847; for making further provisions as to the submission of plans for the approval of the County Council; for prohibiting interference with, or damage to, the structure of bridges; for saving the right of the County Council to widen, improve, or alter main roads and county bridges, and for relieving them from expense in connection with such widening, improvement, or alteration, arising out of the existence of pipes of the Company; for prohibiting the stopping of traffic in consequence of the operations of the Company; for requiring the Company to bear all costs due to congestion of traffic arising out of their operations; for exempting the County Council from liability in respect of damage or injury done to the works of the Company laid at an insufficient depth; and in other respects. Also, to refer differences to an arbitrator.

In their reply, the Company submitted that the provisions of the Gas-Works Clauses Acts, 1847 and 1871, which were incorporated in their existing Acts and Orders and in the proposed Order, had up to the present time been found to afford ample protection to the objectors, and that the circumstances with regard to roads and traffic had not materially altered since the passing of the Northampton Gas Act, 1919. The existing protection to county councils was afforded by general legislation; and they submitted that any change in the protection should be made by an alteration of the general law. It was also stated that the Company were informed that a meeting had been arranged to take place at an early date between the National Gas Council, in conjunction with other sub-surface users of roads, and the County Councils Association, with a view to discussing the question of the legal position of county councils as highways authorities; and they did not therefore propose to offer any further observations on the objections until after this meeting had been held.

Mr. Cash said the meeting referred to had not yet taken place; and he submitted that there was no reason why the Company should be asked to include special protection for the County Council in a matter which, after all, was governed by the general law. Although he was aware that the method of road construction had changed considerably, the provisions of the Gas-Works Clauses Act, 1847, broadly speaking, would seem to be sufficient. The question of road construction had been before Parliament on more than one occasion, and Parliament had not seen fit up to the present, by general legislation, to make any special provision with regard to mains and pipes. The Company were in Parliament as recently as 1919; but the County Council had not asked for protection then, and he did not think the Council could say that they were not then aware of the position in regard to road making. Broadly speaking, the kind of protection asked for by the Council in their objections had been declined by Committees of both Houses of Parliament from time to time in a number of Bills; but, of course, there were Bills in which certain clauses appeared. The great majority of these clauses, however, had been inserted by agreement, and had not been imposed on the promoters by Parliament. He understood that an electric lighting authority in the neighbourhood of Northampton had recently obtained an Order with regard to their undertaking, and that the County Council had not asked for similar protection against them. It was somewhat important, therefore, seeing that the Company were always in competition with electric lighting, that they should not have a burden cast upon them. Further, he believed it was an unknown thing for a clause of this kind to be imposed in respect of an existing area of supply on an application only for an additional area.

Colonel *G. S. Eunson* (Engineer and Manager to the Company) gave details as to the area to be added to the existing limits of supply.

Mr. Honey intimated that he would insert the usual clause to provide that, if the Company failed to supply within five years, their powers might be transferred. The Board of Trade did not want the Company to put a sort of "dead hand" on any of these parishes, so as not to supply themselves, and not to let anyone else do it.

Cross-examined by Mr. Parker, witness said he had always been on very friendly terms with the Surveyor to the County Council, and there had been no difficulty hitherto with regard to mains. He agreed that there might be difficulties in the future, if the Surveyor to the County Council, or his successor, were unreasonable. Asked if it would not be cheaper to settle differences that might arise by reference to an arbitrator, instead of to the Justices (reference to the Justices is provided by the Gas-Works Clauses Act), witness said he did not know how that would work out. *Prima facie* he saw no objection to going to arbitration.

Mr. Parker, referring to the statement that the County Council had not put forward clauses for their protection in 1919, explained that at that time the Council were very short-handed.

As to the period of notice to be given by the Gas Company to the County Council before carrying out works on county roads, witness said that the notice required by the Gas-Works Clauses Act was three days; and he agreed that this was rather short. He did, in fact, give the Council two or three weeks' notice; and when it was suggested that the County Council were moderate in asking for ten days, he replied that he did not think there was anything in this point. He agreed it was reasonable that the Company should be required to submit plans within seven days. As to county bridges, when requiring to carry a main over a bridge he always discussed the matter with the County Surveyor, and did not want to go through the actual structure of the bridges. It was not unreasonable to ask that the Company should not interfere with the structural part of the bridge without the consent of the Surveyor; it being provided that the Surveyor's consent should not be unreasonably withheld.

Replying to further questions, he said the Company should not be required to bear the expense of moving or deepening mains as the result of road widenings. Whether or not it was necessary to deepen a main, depended upon the circumstances. He had put mains at a certain depth at the request of the County Council; and he considered that, once a main was put in at a certain depth at the request of the Council, the Company's liability should cease. After a number of further questions had been put to him, he agreed that it would be of benefit to the Company if a main were removed to a position in which it would not be damaged when widening a road, assuming the question of cost did not arise.

Asked if it would not be reasonable that the County Council should be in the position to take the Company to arbitration if the Company wanted to stop-up the whole of a road, and for the arbitrator to decide whether it was in fact necessary to stop-up the whole road, he said that the possibility of the Company's wanting to stop-up a road wholly would be so remote that there would be no necessity for arbitration. He also maintained that damage to mains caused by steam-rollers operated by the County Council was a matter for which the Council should be responsible.

Mr. Parker then pointed out that general legislation in regard to gas mains was enacted in 1847, whereas that relating to electricity was enacted in 1899; so that the latter was more up-to-date than the former.

Witness replied that the Company did not mind restrictions, provided they applied to all sub-surface users of roads.

Mr. Parker then disputed Mr. Cash's statement that Parliament had declined to give such protection as the County Council were asking for, and said that for the most part decisions of Parliament had been in favour of this protection. Having ascertained from witness that he did not want the passage of the Order delayed, he asked, supposing the meeting between the National Gas Council and the County Councils Association agreed that, to some extent, the protection now asked for was reasonable, and the Order had already been approved, what would be the position of the County Council. Seeing that the Company did not agree to give to the County Council what witness had admitted was reasonable, would he agree to hold-up the Order?

Witness said it must be held-up, but this would inconvenience the people who wanted gas.

Re-examined by Mr. Cash, witness agreed that, if the Company now gave the County Council the protection they asked for, and it was ultimately decided that what they asked for was unreasonable, or that some lesser protection should be given, the Company would be in a worse position than any other public utility company.

Mr. Honey said he believed the view of the Board of Trade would be that they had had enough experience of holding-up Orders pending agreements by outside bodies, and that they must go on with the Order. If they were to wait for an agreement between outside bodies, the Order might drag on for another two years.

Witness, in answer to further questions in re-examination, said it did not matter very much whether general legislation with regard to gas and electricity mains was enacted in 1847 or 1899, because the necessity for the present methods of road construction had not arisen even in 1899. There was no heavy motor traffic then. He preferred to go to the Justices for the settlement of differences, rather than to arbitration, from the point of view of expense.

This concluded the case for the Order.

Mr. Parker, addressing Mr. Honey, said he had a clause which

he would like to submit, without prejudice. He did not wish to be tied to the terms of this clause.

Mr. Honey said in that case he did not want to see it. He could not take a clause submitted to him without prejudice, but would consider the clause required by the County Council.

Mr. Parker said that, if the Board of Trade would give a decision as an opposed matter on his clause, he was content; but the practice of the Board had always been that they would not decide these clause matters, and if there were no agreement between the promoters and the objectors they would not insert a clause in an Order. Therefore the position was that if the Company would not accept a clause, it was useless for him to fight for it at that inquiry, and he must take other steps to secure it. In previous cases the Board had strongly recommended the promoters to try to effect an agreement with the objectors; and he suggested that Mr. Honey might use his good offices in this case, and try to persuade the Company to accept the provisions which their only witness had agreed were reasonable. In the absence of agreement with the Company, and in the absence of Mr. Honey using his good offices to influence them to come to an agreement, he could do nothing. The County Council had no objection to the Order, in principle, subject to reasonable protection, which had been agreed to or given by Parliament in hundreds of cases. While the Company and the Council were very good friends at present, they might not always remain so; and it seemed that the best thing to do would be to arrive at a simple way of disposing of differences that might arise—namely, by arbitration. He suggested holding-up the Order for a short period, to give the parties a chance of coming to an agreement.

Some discussion then took place as to the difference between the legislation relating to gas and electricity mains.

Mr. Parker, in reply to Mr. Honey, said that the Electric Lighting (Clauses) Act, 1899, incorporated the Gas-Works Clauses Act, 1847, but superimposed other conditions. Asked how the Electric Lighting (Clauses) Act added to the provisions of the Gas-Works Clauses Act, he said he was informed that, among other things, it provided for a month's notice instead of the shorter period of three days.

Mr. Cash read an extract on the subject from the sixth edition of Michael and Will's "Gas and Water," and said he did not see any very material difference.

Mr. Honey said the case the County Council had made out was not a case for dealing with this matter in anticipation of general legislation, because their case was that, so long as they had a reasonable surveyor, and so long as the Company's officials were reasonable, they had no difficulty.

Mr. Parker said he had not put it quite so high as that. He had said that there had been no difficulty in the past, but there was no guarantee that there would not be in the future. Reasonable men sometimes fell out. His position was that it was necessary to deal with this matter here and now; otherwise they could never impose these conditions on the Company with regard to the powers it was proposed to give them under this Order.

Mr. Honey said the general view of the Board of Trade on these clauses was that, in the absence of agreement, they would not make any alteration of the general law which ought to apply to all classes of undertakers who had power to break-up roads. The County Council were asking the Board to make an alteration in the general law applicable to a single undertaking, and to put them under different statutory conditions from any other undertaking of the same kind in the county, and any other undertaking of a different class—such as electricity or water—in the county. This the Board of Trade were not prepared to do. If it could be shown that there was a case as regards this individual Company for special treatment, it was open for the County Council to do so, and the point would be considered; but they must not ask the Board to do, in respect of an individual undertaking, what ought to be done, if at all, by general legislation applicable to all undertakings.

Mr. Parker thought it would be found, if the matter were gone into, that the majority of undertakings in the county had similar provisions to those now asked in relation to the road authorities.

Mr. Honey said that all the County Council had done was to say the existing law was insufficient, and that they wanted better protection; but when they were asked what protection they wanted, they would not tell him. They were asking for an undefined alteration of the general law.

Mr. Parker said he did not attempt to differentiate the County Council from any other county council in relation to any other gas undertaking; and he did not say he had a special case in relation to this Company. His contention was that the Act of 1847 was not good enough for to-day; and this position had been recognized by, he believed, every gas company he had come across until this one. It did not seem to him to be of any use going into the details of his clause at the inquiry, because he frankly confessed that his case was not a peculiar one to this Company. The position taken up by the Board of Trade made it necessary for the County Council, if they could not agree with the Company, and if the Board of Trade could not persuade the Company to meet them further, to reserve their opposition for another place.

Mr. Honey pointed out that the County Council's objection did not comply with the provisions of the Gas Regulation Act, inasmuch as it did not state precisely the additions or modifications of the Order asked for.

Mr. Parker intimated that he would agree to be tied to the clause he had referred to previously, if Mr. Honey were prepared to go into it in detail.

Mr. Honey said he did not think he could re-open the matter; it meant starting the inquiry all over again.

Messrs. Ashmore, Benson, Pease, & Co., Ltd., of Parkfield Works, Stockton-on-Tees, have secured a contract for the construction and erection of a large gasholder for the Metropolitan Gas Company of Melbourne, Australia.

At the annual meeting of the Wellington (N.Z.) Gas Company, Ltd., the Chairman (Sir Harold Beauchamp) mentioned that a contract for a gasholder of a capacity of 2 million c.ft. had been placed with Messrs. R. & J. Dempster, Ltd., of Manchester.

INAUGURATION OF COAL-HANDLING PLANT AT NEW MILLS.

Gas engineers from various parts of the country attended the official opening, on March 28, of the retort charging and coal handling plant which, at a cost of £2000, has been installed at the gas-works of the New Mills Urban District Council. The advantages of the machine were explained by Mr. Herbert Spriggs, of Messrs. Herbert Morris, Ltd., of Loughborough, who have installed the plant. Following the inspection, the firm entertained the guests to luncheon at the Town Hall. Councillor Harry Yates (Chairman of the Gas Committee) presided, and was supported by members of the Council.

The Chairman, responding to the toast "Success to the Gas Undertaking," said that during the last few years no small amount of work had been done, though much remained still to be done. They had converted two beds of seven retorts from generator fired and luted lids to regenerator fired with self-sealing mouthpieces, and in addition had taken out a bed of five retorts (direct-fired), replacing them with a bed of seven retorts. They had also replaced an 8-in. cast-iron foul main by a 14-in. steel main, had installed a new Cornish boiler, replaced an exhauster of 8000 c.ft. per hour by one capable of dealing with 30,000 c.ft., repaired the purifiers, and, among other things, installed a 20-ton weighbridge. Extensions contemplated, at an estimated cost of £17,000, included a gasholder of 250,000 c.ft. capacity, four purifiers, washer, scrubber, and a station meter.

Mr. Spriggs, on behalf of Messrs. Herbert Morris, Ltd., presented to the Chairman, as a memento of the occasion, a silver bowl, on which was inscribed: "Presented to Councillor Harry Yates by Messrs. Herbert Morris, Ltd., Loughborough, on the occasion of the opening of the retort charging and coal handling plant, Gas-Works, New Mills, March 28, 1925."

Councillor R. Bradley (Vice-Chairman of the Gas Committee), proposing the toast "The Contractors," paid a high tribute to the firm of Messrs. Herbert Morris.

Mr. Spriggs, responding, spoke of the advantages of the new plant, which, he said, would be cumulative. In a reference to the Council's Engineer, Mr. J. S. Brown, he said they had a man of the right engineering capacity and the right energy.

TRADE NOTES.

"Renrut" Specialities.

Messrs. David Grant & Co., of East Crosscauseway, Edinburgh, have been appointed sole Scottish agents for "Renrut" patent high-pressure service cleansers, syphon pumps, &c., under arrangement with Messrs. Abbot, Birks, & Co., of No. 113, Newington Causeway, London, S.E., who are sole concessionaires.

New Plant for Belfast.

On the recommendation of the Gas Engineer (Mr. J. D. Smith), the Belfast Corporation have accepted the following tenders: Three vertical water-cooled condensers, Messrs. R. & J. Dempster, Ltd.; two Livesey washers, the Whessoe Foundry and Engineering Company, Ltd.; two horizontal scrubber-washers, the Whessoe Foundry and Engineering Company, Ltd.; and three 250,000 c.ft. per hour exhausters, Messrs. Geo. Waller & Sons.

CONTRACTS OPEN.

Vertical Retort Bricks, &c.

The Corporation of Glasgow are inviting tenders for the supply of vertical retort bricks, spurs, and tiles. [See advert. on p. 138.]

EXTENSIONS.

New Plant for Burnley.

The Burnley Town Council have adopted the recommendation that the Town Clerk, Gas Engineer, and Borough Surveyor shall take the necessary steps to prepare and submit as soon as possible a complete scheme for the erection of the first unit of the new gas-works at Old Hall to the Unemployment Grants Committee of the Ministry of Health.

New Plant for Blackburn.

On April 2 the Blackburn Town Council decided to embark on schemes for the relief of unemployment, including the erection of a holder at the Greenbank Works, and the provision of oil gas plant.

Blyth Gas Company.

The Company have in view important extension schemes. These include the erection of a 300,000 c.ft. holder at the Bedlington Works and a water condenser to deal with one million c.ft. of gas per day at the Blyth Works.

Coventry Gas-Works.

The Coventry Gas Committee recommend the City Council to approve of the second section of the scheme of extension at the gas-works at Foleshill being proceeded with at an estimated cost of £266,310, and that application be made to the Board of Trade for a Special Order under the Gas Regulation Act authorizing the borrowing of £350,000 for this purpose, and for the purpose of mains. The total scheme, which involves an estimated cost of £425,000, was originally approved in 1919, when it was decided to carry out the work of extending the plant at the gas-works in two sections. The work which it is now proposed to proceed with includes the installation of vertical retorts of 2½ million c.ft. capacity per diem, at a cost of £96,000, and a 5 million c.ft. holder, at a cost of £90,000. In addition, it is proposed to extend the railway sidings at the works at an estimated cost of £18,500.

NORTH-EAST COAST COAL TRADE.

From our Own Correspondent.

Apart from an increased demand for prompt shipments of Northumberland steam coals, which is of little interest to gas coal consumers, the market was again featureless in the past week. There are very few signs generally of the usual rush to fill requirements before the holiday, and shippers have no anxiety about finding ample supplies to get their boats away.

Gas coal trade is no brisker, and, while the better sorts still manage to maintain fairly good prices, much more trade could be dealt with.

Wear Special makes indicate 20s. 6d. f.o.b., and best qualities 10s. 6d. to 20s. Seconds and others are 17s. to 17s. 3d., with considerable competition even at these prices.

COAL TRADE IN THE MIDLANDS.

From our Local Correspondent.

Some of the gas-works managements are beginning to sound the market with regard to new annual contracts from midsummer. Collieries have been invited to state their terms on the assumption that they will be willing to make substantial concessions if they can assure themselves of outlets for any considerable proportion of their potential production. Reductions of 2s. to 3s. on current contract rates are looked for, though some of the consuming interests put the depreciation at a higher figure. Unless the position undergoes some unforeseen change between now and June, contracts will be on a smaller scale than those made last year, when recent difficulties with regard to deliveries led engineers to seek an unusually ample margin of safety. Consumptive demand having fallen short of calculations, there is every likelihood of considerable balances being carried over from the current contracts into the new period. These balances will modify any savings which gas undertakings may effect by the bargaining which has now begun. Conditions in the coalfields show no improvement. The outlook is so uncertain that many collieries cannot see their way to make ends meet on a lowered earning capacity. However it may be with the newer pits, which, from their natural advantages and modern equipment can get coal economically, the prospect is menacing for many properties.

There are signs of slackening in the active demand that has ruled for a long time past in the best grades of house coal; individual collieries notifying a reduction of 2s.

YORKSHIRE AND LANCASHIRE COAL TRADE.

From our Local Correspondent.

Gas coals under contract in Yorkshire and Lancashire are easy, and it is anticipated that there will be some concession in regard to renewals during the next two or three months.

House coals remain steady, with indications of slightly reduced figures after Easter.

Industries are still quiet, with little business available for the lower-grade fuels at discounted prices.

Export remains dull; but there are indications of a slight recovery, orders at low figures being on the market at the present time.

At Hull at the week-end Humber bunker and export prices (f.o.b. usual shipping ports) were: South Yorkshire: Hards, Association, 19s. 3d.; screened gas coal, 19s. 6d.; washed trebles, 20s. 6d.; washed doubles, 17s. to 17s. 6d.; washed singles, 17s.; washed smalls, 13s. to 13s. 3d.; unwashed doubles, 15s. 9d. to 16s. 3d.; rough slack, 11s. to 11s. 6d.; smithy peas, 20s. to 21s. West Yorkshire: Hartleys, 17s. to 19s.; screened gas coal, 19s.; washed trebles, 17s. 6d. to 18s. 6d.; washed doubles, 16s. to 17s.; washed singles, 16s.; washed smalls, 12s. 6d. to 13s.; unwashed trebles, 18s.; unwashed doubles, 13s. 6d.; rough slack, 11s.; coking smalls, 10s. 3d. to 10s. 9d. Derbyshire and Nottinghamshire: Top hards, 19s.; washed trebles, 18s.; washed doubles, 17s. 6d. to 18s.; washed singles, 17s.; washed smalls, 12s. 9d.; unwashed doubles, 15s.; rough slack, 10s. 6d. to 11s. Yorkshire, Derbyshire, and Nottinghamshire: Screened steam coal, 15s. 3d. to 18s.; gas coke, 21s. to 23s.; furnace coke, 17s. 3d. to 18s. 6d.

In Lancashire, best qualities of slack are in good demand at prices ranging up to 16s. 6d. per ton, but common slacks are weak.

Gas Cookers for Stoke.—The Stoke-on-Trent Corporation Gas Committee are seeking sanction to a loan of £10,000 for the purchase of gas cookers.

Southend Gas Company.—It was stated in the report adopted at the annual meeting of the Company that the consumption of gas last year was 10 p.ct. more than in 1923, and that, in spite of considerable recent expenditure—a new holder, purifiers, &c., having been installed—the capital per million c.ft. of accounted-for gas was a satisfactory feature, and suggested that the Company occupied a strong position. The Chairman (Mr. J. H. Burrows, J.P., C.A.) pointed out that the gas sales last year reached nearly 902 million c.ft., and that the 10 p.ct. increase then recorded followed upon an increase of 17½ p.ct. for 1923. Ten years ago the sale of gas did not reach 440 million c.ft. "I am," remarked the Chairman, "greatly indebted to Mr. J. T. Randall, your Secretary, of whom it may be said 'Ever faithful, ever true.' I am also similarly indebted to Mr. T. F. Canning, a man who has overcome substantial difficulties, and of whom we can assert that each successive year's experience contributes additional justification of our choice of him from a short list of strong applicants." Dividends were declared on the original consolidated and new ordinary stocks at the rate of 6⅜ p.ct. per annum, on the new ordinary "B" stock 5¾ p.ct., and on the redeemable preference stock 7 p.ct., less income-tax.

CURRENT SALES OF GAS PRODUCTS.

The London Market for Tar, Tar Products, and Sulphate.

London, *April* 6.

A little more business is offering in the London tar products market in pitch, and the price is firm at about 42s. per ton in bulk at makers' works.

Creosote is rather quiet at about 7¼d. per gallon net and naked at works.

Solvent naphtha 95/160 is quite firm at about 1s. 8d. per gallon; other spirits remaining unchanged.

Tar Products in the Provinces.

April 6.

The markets for tar products are unaltered.

Pitch is still very dull, and even the low prices quoted to-day do not induce manufacturers on the Continent to purchase. They might possibly be interested in some quantity for next season at to-day's prices, but quite naturally the manufacturers feel the market is so low that they can do no harm by waiting.

Creosote is unaltered. There is a fair home demand, and a renewed inquiry for export is looked for at an early date.

Benzole is a little easier, doubtless due to the disappointment that an advance has not taken place in the price of petrol.

Solvent naphtha is steady, and the majority of manufacturers are well sold. Heavy naphtha is dull and difficult to sell.

Carbolic and cresylic are entirely neglected.

Naphthalene is almost unsaleable.

The average values for gas-works products during last week were: Gas-works coal tar, 29s. 3d. to 34s. 3d. Pitch, East Coast, 40s. to 41s. f.o.b. West Coast—Manchester, 35s. to 36s.; Liverpool, 36s. to 37s.; Clyde, 39s. to 40s. Benzole, 90 p.ct., North, 1s. 6½d. to 1s. 7¾d.; crude, 65 p.ct., at 120° C., 9¼d. to 10¼d., naked at makers' works; 50-90 p.ct., naked, North, 1s. 1d. to 1s. 2d. Toluole, naked, North, 1s. 7½d. to 1s. 8¾d., nominal. Coal-tar crude naphtha, in bulk, North, 7½d. to 8d. Solvent naphtha, naked, North, 1s. 5d. to 1s. 6d. Heavy naphtha, North, 1s. 1d. to 1s. 2d. Creosote, in bulk, North, liquid, 6¼d. to 6¾d.; salty, 6¼d. to 6¾d.; Scotland, 6d. to 6¾d. Heavy oils, in bulk, North, 6⅝d. to 7d. Carbolic acid, 1s. 6d. to 1s. 7d. prompt. Naphthalene, £12 to £15; salts, £4 to £5, bags included. Anthracene, "A" quality 3d. per minimum 40 p.ct., purely nominal; "B" unsaleable.

Exhibition at Brighouse.

Great interest was taken in an exhibition which was organized by the Gas Department of the Brighouse Corporation, and held from March 2 to 7. All types of cookers were on view, including the Standard Cooker of the National Gas Council (exhibited by the Parkinson Stove Company, Ltd.), which is supplied on simple-hire terms by the Brighouse Gas Department. Among other cookers were the "New World" and "New World Junior," of Radiation Ltd., and the "Chef" cooker by Messrs. William Sugg. As to fires, these were well represented by the "Cosie" of the Parkinson Stove Company, the "Cinderella" of Messrs. R. & A. Main, Ltd., and a number of excellent examples manufactured by the Cannon Iron Foundries, Ltd. An interesting exhibit was that of the Gas Department in collaboration with a local firm, which was a successful attempt to show a first-class bathroom fitted with geyser, heated towel-rail, and a novel shaving fitting. A portion of the exhibit was devoted to coke, and samples of various grades were shown. Excellent results were the outcome of the week's publicity—results which reflect great credit on Mr. C. R. Ingham, the Engineer and Manager. The value of the sales was approximately £1000, which is about the normal annual sale of appliances by the Department. The great value of the exhibition, however, lies not in the actual sale of appliances, nor in the increased consumption through these new appliances, but in the increased consumption through existing apparatus, as the result of the educational work.

Dundee Gas-Works.—At a recent meeting of the Dundee Gas Committee it was reported that tenders for 100,000 tons of coal had been accepted at an average price of 21s. 6d. per ton—a drop of 5s. 6d. per ton on last year's purchases. A report by Mr. James Dickson, the Gas Manager, was read. In this he states that the storage capacity is now 4¼ million c.ft., and the maximum daily output 7¼ millions. The ratio of storage capacity to daily output is, he considers, low. With regard to the maintenance of gas appliances, he recommended a systematic visitation, and estimated that sixteen men, working on eight districts, could cover the city, and pay at least two visits per annum to each consumer.

Londonderry Gas Light Company.—Some trenchant criticisms of the Electricity Department of the Londonderry Corporation were passed by Mr. R. H. Smyth (Chairman) at the annual meeting of the Gas Company. It was now three months, he said, since they drew attention to the pamphlet issued by the Electricity Department in which it was stated that under their so-called "free wiring scheme" electricity was the most economical form of illumination. The Gas Company stated the actual facts—viz., that, so far from being the most economical illuminant, electricity, under this scheme, was actually 100 p.ct. dearer than gas. In justice to themselves they could not let the statement regarding the cost of the respective illuminants go unchallenged, but a more serious question was involved from the ratepayers' point of view, as to which the Company, as one of the largest ratepayers in the city, had a right to protest. To inaugurate the scheme, many thousands of pounds of the ratepayers' money was to be spent in laying cables, supplying expensive prepayment meters, wiring, and fitting in the smaller houses in the city. When the householder found that his lighting expenditure was increased, he would revert to gas. In another portion of his speech Mr. Smyth mentioned that 250 consumers had been added during the year. Reduction in prices represented £8000, or 17 p.ct. less than last year, which had been balanced by reduced expenditure. The new manufacturing plant had been completed, and was giving entire satisfaction. New mains and replacements would shortly be completed.

STOCK MARKET REPORT.

The financial crisis in France dominated the situation on the Stock Exchange last week. The rumour early in the week that the note circulation was to be increased was dissipated by M. Herriot's denial, which was followed by the resignation of the old and the appointment of the new Minister of Finance. At the moment it is impossible to say what effect the change will have on the financial policy of France. There was, however, a fair amount of selling of French Rentes and railway sterling bonds. The success of the Conversion Loan should be very gratifying to the taxpayer, as the annual saving of about £100,000 indicates a possibility of a still greater relief in the future, although perhaps not in the immediate future.

On the whole, the week closed more cheerfully, and the general tone was steady, although business was on a small scale. The Industrial and Miscellaneous Markets were rather subdued, and the Gas Market depression continued. There was renewed interest in the Newspaper group; Allied Newspapers and Daily Mirrors being prominent. Breweries were in demand, and there was a big jump of 55 points in Guinness to 610. Tobaccos also were well supported; Imperials, on rumours of another bonus, and Carreras on the remarkable expansion of business, were both marked up.

Brentford "A" and "B" stocks dropped another 3 points to 100-105; Commercial 4 p.ct. and 3½ p.ct. stocks 1 point and 2 points respectively. Dividend proximity accounted for the further rise of 1 point in Imperial Continental ordinary.

The following transactions were recorded during the week:—

On Monday, Aldershot "C" 79, Alliance and Dublin 70⅜, Bournemouth "B" 12⅜, Continental Union 7 p.ct. preference 91, European 7¼, 7⅜, Gas Light and Coke 89¼, 89½, 89⅜, 3½ p.ct. maximum 63½, Imperial Continental 181, 181½, Primitiva 8s. 4½d., 8s. 10¼d., South Metropolitan 94½, 94⅜, 95, Tottenham "B" 99½, 100. Supplementary prices, Brentford 6 p.ct. mortgages 98½, Cheltenham 5 p.ct. maximum 78¾, 4½ p.ct. debenture 61, Gloucester consolidated 89¼, 89⅜.

On Tuesday, Alliance and Dublin 69, Bombay 5¼, Brentford "A" 100, British 113½ *ex* div., Gas Light and Coke 88½, 89, 89½, 89⅛, 3½ p.ct. maximum 64, 4 p.ct. preference 79½, 79½, 3 p.ct. debenture 60½, Imperial Continental 179, 180½, 181, Ottoman 5s., Primitiva 8s. 9d., South Metropolitan 94½, 95, 3 p.ct. debenture 59½, 60½, 61½, Tottenham "B" 98.

On Wednesday, Alliance and Dublin 69, 69⅜, 69⅜, British 113 *ex* div., Commercial 3 p.ct. debenture 58, European 7⅜, 7½, Gas Light and Coke 88½, 88⅞, 89¼, Imperial Continental 181, Liverpool 7 p.ct. preference 105½ *ex* div., Primitiva 8s. 9d., 4 p.ct. 1st debentures 80¾, San Paulo 6 p.ct. preference 77½, 77⅝. South Metropolitan 94½, 95, 3 p.ct. debenture 61¼, Southampton 84, 84½. Supplementary prices, Hartlepool 5 p.ct. maximum 89⅜, Uxbridge Maidenhead 4 p.ct. debenture 75, 75⅛.

On Thursday, Aldershot "C" 79½, British 112, 113, Gas Light and Coke 89¼, 89⅜, 3½ p.ct. maximum 63, 4 p.ct. preference 79½, Imperial Continental 181, 182, Montevideo 65½, 65¾, South Metropolitan 95⅛, 95¼. Supplementary prices, Dover 5¼ p.ct. debenture 102½.

On Friday, Alliance and Dublin 4 p.ct. debenture 66, 66½, Bombay 5⅛, Bournemouth "B" 12⅜, Continental Union 37, Gas Light and Coke 89, 89⅛, 3½ p.ct. maximum 63, 4 p.ct. preference 79½, 3 p.ct. debenture 60, Imperial Continental 180½, 181, 181½, 182, Liverpool 7 p.ct. preference 104⅜, 105⅛. Primitiva 8s. 6d., 8s. 11¼d., South Metropolitan 94⅜, 95, 95⅛, South Suburban 5 p.ct. 99, 101, Tottenham "B" 99, 100. Supplementary prices, Aldershot 7 p.ct. bonds 105⅜.

Extremely easy conditions existed in the Money Market at the close of the week. Old day-to-day loans were continued at 3½ p.ct., while fresh money was available at 3 p.ct. Discount quotations remained weak in tendency, but the average rate at which Treasury Bills were allotted—£4 5s. 7·15d. p.ct.—had a hardening influence.

The feature of the Foreign Exchange Market was the erratic movement in the French franc in consequence of the Government's financial position. The Paris cheque closed on Friday at 92.55; but on Saturday the rumours of restorative measures to be introduced in the Chamber had a salutary effect, and the rate moved in favour of France to 91.85. Sterling was quiet but firm at 4.78¼. Belgian francs closed at 94.05, and Italian lire at 116⅞ on Saturday.

Silver was quiet, and the price remained at 31 7/16d. per oz. Gold was also unchanged at 86s. 6d. per oz.

The Bank Rate is 5 p.ct., to which it was raised from 4 p.ct. on March 5. Bankers' deposit rates are 3 p.ct. The deposit rates of the discount houses are 3 p.ct. at call and 3¼ p.ct. at notice.

THE FLOW OF GASES and PROPORTIONING GAS MAINS.

By

F. SOUTHWELL CRIPPS, Assoc.M.Inst.C.E.

WALTER KING, Ltd., "Gas Journal" Offices, No. 11, Bolt Court, Fleet Street, E.C.4.

New Company.—The Geyser Manufacturing Company has been registered, with a capital of £1000.

Maryborough (Queensland) Gas and Coke Company, Ltd.—The Directors' report for the half-year ended Dec. 31, 1924, showed a profit of £1943. Out of this the Directors recommended the payment of the usual dividend of 6 p.ct. per annum, together with a bonus of 1 p.ct.

Wandsworth Gas Company's Price Increase.—The Directors of the Wandsworth, Wimbledon, and Epsom District Gas Company regret that they are compelled to raise the price of gas by ⅜d per therm (approximately 2¾d. per 1000 c.ft.) from the taking of the meter indices at the Lady Day quarter; and this will apply to all consumers in the various areas supplied by the Company. This increase, which is due to the heavy fall in the values of residuals and the extra cost of living allowance, not only reduces the dividend payable to the stockholders, but also has the effect of reducing the profit-sharing bonus payable to the workmen.

Wembley Gas Exhibit.—Alderman George Ratcliffe (Chairman of the Leeds Corporation Gas Committee) emphasized the value of advertising, in the experience of the Gas Department, in the course of discussion on a grant to the Wembley Gas Exhibit, at a meeting of the Leeds City Council on April 1. He said he had always been a believer in advertising as a stimulus to trade, but he had never observed such remarkable results as during the past eighteen months in connection with the Leeds Gas Committee. They had had a surplus of more than 20,000 orders in the department within the past six months—every one of them for new consumers of gas. The Council agreed to grant £500 towards the new Wembley Gas Exhibit.

South Metropolitan Gas Bill.—In connection with the South Metropolitan Gas Company's Bill, the Croydon Town Clerk reports having obtained an undertaking from the promoters' agents: (1) To add a provision to clause 2, that any agreement therein authorized relating to working arrangements between the South Metropolitan Gas Company and certain other gas companies, shall be submitted to the Council of any county or county borough within which any part of the area of a party to the agreement is situate; and such council shall be entitled to make representations to the Board of Trade and be heard thereon before any such agreement is approved by the Board. (2) To add a new clause (7*a*) providing that the South Metropolitan Gas Company shall give notice by advertisement of the submission to the Board of Trade of any scheme for amalgamation or purchase under their Acts of 1876 or 1920 outside the Metropolis; that copies of such notice and scheme shall be sent to the county and county borough councils in which any part of an undertaking proposed to be amalgamated or purchased is situate; and that the Board of Trade shall receive any representations of such Councils thereon.

Inquiry at Blackburn.—On March 24, an inquiry was held by Mr. R. C. Cox, of the Ministry of Health, into an application by the Blackburn Corporation to borrow £60,000 for the installation of gasholders and other plant at the Greenbank Works. Sir Lewis Beard (Town Clerk) said that in 1916 the yearly output was 769 million c.ft. At present it was 1027 millions.

The Stoke-on-Trent Corporation Gas Committee are to spend £300 on repairs caused by storm damage at Etruria Gas-Works.

The Belfast Corporation have granted the free use of the Ulster Hall for a gas exhibition in September next.

The manufacture of gas has ceased at St. Anne's Works. Both plants in the borough of Lytham-St. Anne's (now amalgamated) are thus out of action.

Messrs. Tilley Brothers have, for family reasons, converted their business, which has been in existence for over a century, into a limited company, with head offices at No. 39, Victoria Street, Westminster—the premises at No. 53, Kingsland Road, E., having been disposed of.

At the annual meeting of the Tamworth Gas Light and Coke Company, Alderman G. Hoskison (Chairman of Directors) announced that the Company were going on satisfactorily. He moved that the usual half-yearly dividend of 7½ p.ct. on the old shares, and 5¼ p.ct. on the new shares be paid. Mr. Hunt seconded, and it was carried.

Speaking at a meeting of the Darlington Corporation on April 2, Mr. S. Long, Chairman of the Gas Committee, said that, though the Committee had given nothing this year towards the rates, they had benefited the town in many ways. They had found a considerable amount of work for the unemployed, and the price of gas had been extremely low.

The members of the Football Team of the Portsea Island Gas Light Company's Athletic Club played a semi-final match on the Fratton Park Football Ground against the Royal Marines on Wednesday last. Mr. Carmichael, the Engineer, and several members of his staff were interested spectators of a most exciting match, which ended in a victory for the Company's players by 2 goals to 1. Sound defence was a characteristic feature of the team.

At a social gathering at the Bridge Hotel, Newcastle, on April 3, five old servants of the Newcastle and Gateshead Gas Company, who have retired, were the recipients of presentations in the form of cheques. Two of the recipients, Mr. F. Lunn and Mr. J. Golightly, had almost 100 years' service between them, while the remaining three, Mr. W. Ellison, Mr. J. Farbridge, and Mr. C. Lloyd, had a total of over 80 years. They were all members of the Distribution Department. Mr. R. W. Copeland, President of the Welfare Club, presided, and the presentations were made by Mr. R. Fairless, Chief Inspector of the Distribution Department, who spoke in appreciative terms of the services rendered by the recipients.

"JOURNAL" Publications.

"Journal" Diary and Gas Calendar, 1925.
Size: 7″ × 4¾″
Price 7/6 post free.

Gas Salesman's Diary and Handbook, 1925.
Size: 8″ × 5¼″
Price 3/6 post free.

Transactions, Associations of Gas Engineers and Managers.
Size: 8¾″ × 6⅛″
Price 10/6 post free.

The Rating of Gas and Water Undertakings.

EDITORIAL NOTES.

The Coming Institution Meeting.

THE prospects for the Annual Meeting of the Institution of Gas Engineers, from June 9 to 12, are of a conspicuously attractive character. There may be good reliance upon the President, Mr. J. Ferguson Bell, M.Inst.C.E., to make the week technically profitable and otherwise enjoyable to the members and all visitors. Of the latter, there is expectation that we shall have the felicity of welcoming several from abroad. The mornings and afternoons of both Tuesday and Wednesday and the morning of Thursday will be devoted to the consideration of technical and business matters. But, dealing first with the lighter side of the programme for the week, there will be on Tuesday evening a reception and dance at the Connaught Rooms at the invitation of the President and Mrs. Bell; and after the morning sitting on Thursday there will be relaxation for everyone during the remainder of the week. On Thursday afternoon those who are in search of scientific and technical interest will have a choice of alternative visits. They may explore the almost boundless activities and the marvels of the equipment of the National Physical Laboratories at Teddington; they may go and investigate the plant under construction at the Fulham Works of the Gas Light and Coke Company; or the thorough character of the work constantly proceeding in, and the fine equipment of, the Chemical and Physical Laboratories and Burner Department of the South Metropolitan Gas Company will be open to inspection. This will be a magnetic feature of the afternoon's engagements. To both the Teddington and the Old Kent Road visits, ladies are invited, and at both places they may be sure of receiving a very cordial welcome. On Wednesday and Thursday evenings, there is confidence in saying that Wembley will draw numerous visitors from the gas men and their ladies assembled in London.

A glorious programme of interest and enjoyment has been arranged by the President for Friday. The only thing over which he has no control is that unruly element the weather; but we shall all pray that Friday above all days of the week will in this respect be of a propitious character. A special non-stop saloon train will early in the morning leave St. Pancras for Derby—the scene of the President's daily professional life. Not only will the Litchurch Lane and Cavendish Street Gas-Works, the Gas Offices, and the Showrooms be open for inspection, but the Locomotive, Carriage, and Wagon Works of the L.M. & S. Railway will be on view; and the ladies—and they only—are invited to visit the Royal Crown Derby Porcelain Works. We feel sure that such an opportunity of inspecting the processes and products of this world-famed place will not be missed by them. At lunch, the visitors will be the guests of the Chairman and Directors of the Derby Gas Light and Coke Company, who are proud of the position to which their General Manager and Chief Engineer has attained in the professional and administrative work of the gas industry; and they will be equally proud of his large following whom they will have the happiness of welcoming. This does not finish the pleasures of the day, for in the afternoon there is to be a motor coach drive to the celebrated Haddon Hall. The details of all these engagements were given in our issue for April 1, p. 59.

Regarding the meetings, honour is to be done to that prominent technician and administrator in the industry, Dr. Charles Carpenter, C.B.E., by the presentation to him of the much coveted and prized Birmingham Medal. The technical work which will engage the members is of a high order, and appropriate to these progressive times for the industry. There will be the President's Address, which is bound to be far-reaching in thought regarding current problems, of which he has a notorious aptitude for keeping abreast. Important items in the programme will be the reports of the Educational Advisory Committee, the Gas Investigation Committee, the Wrought-Iron Tubing Committee, the Joint Refractory Materials Research Committee, the International Commission on Illumination, and the Gas Research Fellowship. As to the papers, these are not numerous; there are only five, but they will—the names of the authors warrant us in saying—be of a quality which will give scope for excellent discussion regarding matters upon which we all require to know more and more, or to which closer and more serious attention should be directed. There will be from the members a rousing welcome for the President of the Société Technique de l'Industrie du Gaz en France (M. L. Rolland d'Estape) when on Tuesday he submits his paper on the "Tankless Gasholder at the Etablissements Arbel, Douai, France." The subject is one which has very live interest among gas engineers in this country. It is well known that a number of these tankless holders, of small and large capacity, are in existence on the Continent. But about them there is information British gas engineers would like to have. Among the questions that may be asked will be: Are they going to save capital expenditure in foundations, tanks, and iron or steel work by adopting the rigid form of holder in preference to the tank column-guided or spiral-guided forms? To what extent and in what ways are such holders likely to affect the cost of maintenance? If, on balance, this type of holder design (given equal capacities) does not save money, does it offer advantages superior in character and in the aggregate which would justify preference in their favour? There will be many inquiries—some critical; but we have no doubt that those engineers who have made a study of these holders will be able to satisfy their interrogators. Then Mr. W. M. Carr will present a paper on the "Selection, Design, and Construction of New Carbonizing Plant at Stretford." The subject is one which will give latitude for discussion. The members are again to have the pleasure of the presence of Prof. C. V. Boys, F.R.S. (one of the Metropolitan Gas Referees), who will submit a paper on "Developments in Gas Calorimetry," and not a few members will then hope to hear when they may expect that the new recording gas calorimeter will be prescribed by the Referees for adoption under the Gas Regulation Act. Another subject which demands from gas men earnest consideration is that of "Town Gas for Motive Power;" and this question will be submitted for consideration by Sir Dugald Clerk, K.B.E., F.R.S., who is pre-eminently qualified to infuse into the minds of gas men the desire for stronger activity in defending and expanding the position of the industry in this regard. Finally, there will be a paper by Mr. George Evetts, M.Inst.C.E., on the "Economics of Gas Production on the Thermal Basis." The mere mention of the

name of the author of the paper is sufficient assurance that what he presents will be a thorough investigation of the matter in hand. We heartily congratulate the President and Council of the Institution upon the technical programme and the attendant arrangements for the forthcoming meeting.

Cost of Inspection and Maintenance.

Scotland has taken a good part in the lead for the adoption of an "all-in" policy in respect of the inspection, adjustment, and maintenance of gas-consuming appliances, charging only for the material used. We are strongly convinced that the protagonists in this matter, whatever their geographical quarter, are right, and that they are doing a genuine service to the industry by pegging-away on all possible occasions at this really vital matter—especially those who practise to the full what they preach, and so can speak from experience. At three or four meetings of the North British Association of Gas Managers, the question has been under consideration, and is being kept to the front as a policy essential to the industry. Those who are the strongest advocates are those who have not only intimate knowledge of the old conditions of allowing the ways and means of utilizing gas to take care of themselves, as the indifference and ignorance of consumers permit, but have had experience of the advantage of supervision. We are confident that the relating of these experiences will do more to influence those who are still reluctant to adopt this policy than all the arguments, though irrefutable, without experience. Both arguments and experiences can be obtained from the valuable papers read by Mr. J. W. Napier, of Alloa, and Mr. George Keillor, of Greenock, which we published last week, and the notable statement by Mr. J. W. M'Lusky, of Glasgow, which we report this week. Of the facts of the question, all three have long experience as the foundation of their advocacy; all three tell us plainly that—proud as we may be of the progress the industry is making—there is in more cases than has even been dreamed of by many responsible gas men a condition of things existing the other side of domestic and industrial meters of which we cannot be proud, and which, with neglect of adjustment and maintenance in other cases, is the worst enemy to the stability of the industry which it has to face in these competitive times.

We do not wish on this occasion to labour the seriousness of the position; what we do wish is that those gas managers who have not yet made survey of the internal conditions in their area of supply, should do so, and then determine their policy, having regard to the keener competition which gas has to meet through electricity undertakings desiring the fuller development of, and greater diversity in, their loads. The gas industry has got to resist this by the best means at disposal; it has at the same time to develop its own load. As to the former, the most effective method is to incorporate in the trading policy an inspection and maintenance scheme, and that is also one of the best roads to the development of business. With the large connection the gas industry already possesses, it is more difficult than formerly to get new customers; but with competition surrounding, and with neglected lighting, heating, and cooking appliances giving indifferent service, it is easy to lose old customers. It is therefore an absolute necessity, in order to obtain increased custom through existing services, that there shall be satisfaction on the part of the consumers with their present appliances. That is so obvious that it is almost superfluous to write it; and yet apparently its significance is not appreciated by some administrators. Mr. Napier, Mr. Keillor, and Mr. M'Lusky, one after the other showed that inspection, adjustment, and maintenance, and the greater personal contact between consumers and competent representatives of their undertakings have brought about a larger demand for gas appliances which should be credited to the inspection and maintenance system—even though it is impossible to make a positive financial assessment to set against the cost of periodical house-to-house visitation to establish and maintain high efficiency. Beyond this there is a material credit in the retention of old customers, who, when once they have borne the cost of effecting a change, do not feel disposed to make a return, although they learn there is not the same economy and efficiency as under the older system when properly treated.

The question of the cost of adopting the policy of inspection, adjustment, and maintenance, is one that has perhaps, through a mistaken idea, caused much halting and deferment in adoption. The gas industry is the debtor to Mr. M'Lusky for the enlightening information he has from time to time furnished as to the financial aspect of the policy. Each time he has spoken in regard to it, the case has been better than on the previous occasion. The secret of this is that, as development of the application of the system proceeds, the cheaper it is per 1000 c.ft. or per therm to carry it on. We are also inclined to think that, as the rough places are made smooth in an area of supply, inspection, regulation, and maintenance become an easier matter; and, moreover, the competence of the men in the work becomes greater. These are in our view factors which operate to bring about a lower cost. It will be remembered that, after the work had started in a trial area in Glasgow, with its ghastly revelations as to what existed, Mr. M'Lusky estimated the cost at 1¼d. per 1000 c.ft. After a time, the actual cost was 1¼d. But now with the spread of the system, the elimination of what was bad, and the greater efficiency of the men through experience of the work, the cost has come down to 0·592d. per 1000 c.ft.—constituted of: Labour, 0·375d.; material, 0·084d.; and overhead charges, 0·133d. Per therm, the figures are: Labour, 0·08d.; material, 0·018d.; and overhead charges, 0·028d.—a total of 0·126d. It is estimated that in Glasgow there are 1,250,000 appliances in 213,447 premises; and now 995,038 burners and appliances are being maintained as compared with 410,000 appliances when Mr. M'Lusky reported upon the position last September. The number of appliances has increased by 140 p.ct.; and the expenditure has been reduced as stated from 1¼d. to 0·592d. per 1000 c.ft. There might be a slight increase in the cost in more restricted areas; but there may be good confidence, based on the experience of Glasgow, that the initial costs per 1000 c.ft. or per therm or per appliance will be reduced to a modest figure. The question is, Is the result worth the expenditure? Our reply is positively in the affirmative. What is the cost of the loss of custom and a heavy complaint list in comparison? Does the Glasgow consumer object to paying 0·126d. per therm more to realize a higher efficiency, a lower gas account for an equivalent amount of work, and greater satisfaction? The expenditure pays the consumer, as it certainly does the gas undertaking.

Coking Experts and the Coke Competition.

The question has been put to us whether technical men engaged in coke-oven practice are eligible for participation in the Coke Competition. We may say at once that welcome will be given to contributions from any source which in any way contain suggestions of value in respect of coke to the gas industry; and this applies to the technical men engaged in the coking industry. There are various reasons why they should come in as participants. There is no question from what is seen to-day in respect of the business relations between the coke-oven industry and the gas industry that—gradually it may be, but certainly—the two industries will have to draw together closer and closer. In respect of the question of the co-ordination of the utilization of the fuels of the country, we have the growing transfer of coke-oven gas to suitably situated gas-supply undertakings; and the millions of cubic feet so purchased annually is a largely growing quantity, and this is likely to continue to be so. Also in respect of sulphate of ammonia and benzole, the two industries are co-operatively concerned in propaganda and sales. Thus the tendency is for closer identity between the two industries; and, looking forward, it is easy to conceive that in time they will present a still more united and common front. Furthermore, the difficulties of the coke industry in regard to the demand for metallurgical coke being far short of productive capacity have, through industrial depression during the past few years, been very great; and the prospect is that, with the return of better conditions on the Continent, there may be a further substantial decline

in the requirements of other countries for our furnace coke. Therefore, naturally, the coking industry has been looking round to ascertain in what way it can extend its markets for coke; and it is now well known that there are coke-oven plants which are producing coke suitable for domestic and industrial purposes. Taking all these things into consideration, we could not shut out from the competition the ability and talent which exists in connection with coke production in the related industry. But, in saying this, our friends of that industry will bear in mind that the object of the competition is primarily to encourage improvement in the production, handling, and utilization of domestic coke, though this is not the sole aim.

Publicists and the Coal and Power Problem.

No excuse need be offered for referring to this subject so soon after the Southern Association meeting, because the gas industry (as has been frequently emphasized in these columns) is so deeply concerned in altering, to the advantage of the nation at large, the threatened trend of things. We are sorry to see that so many of our publicists who are influences in shaping public opinion, are, through nescience and misunderstanding, helping to do the shaping in the wrong direction. These publicists require to be educated to see the error of their ways in this particular. Take as an example Mr. G. L. Garvin, whose articles in "The Observer" are always widely read. In the course of a recent outpouring on the subject, he alluded to electricity and oil as being the great solution of our problem. Whittling down what he said, we come to super-power stations and low-temperature carbonization. He predicts that the World Power Conference at Wembley last year taught us many lessons; but we fear that, in the multiplicity of counsels, Mr. Garvin has lost his way. He also credits Mr. Lloyd George with having rendered better service on this subject than any other public man, though he made the incidental error of mixing democratic emotion with a severely technical subject. We feel that Mr. Garvin's view should have a wider application than to Mr. Lloyd George; perhaps it might with excellent validity be applied personally. We agree with him absolutely that, "if we mean to be again a progressive and thriving and confident nation," we must undertake "a technical revolution on a national scale by making a modern use of our basic product coal." But our views distinctly disagree as to the nature of the "technical revolution." Mr. Garvin submits that coal should be converted at super-power stations partly into electric current available for "machine force," transport, heat, and light throughout the country; partly into fuel oils and other valuable derivatives. It would be interesting to know the fundamental data upon which this moulder of public opinion bases his ideas of what should be done.

For our own part, we object to coal being used, especially for producing electricity for general heating, at super-power stations at from only 18 to 20 p.ct. efficiency, the energy being transmitted about the country at heavy cost and loss. These are technical matters that popular writers do not understand, nor can they be expected to do so. "A clean and smokeless civilisation" is not to be obtained through the uneconomical means Mr. Garvin suggests—uneconomical to both the nation and the individual. The gas industry can show a better way; and if Mr. Garvin will only study the economics of the question from all points of view, we are confident he will become a convert to the proposal for an examination of the whole question from all points of observation, and not from the single one which appears to be so popular in the lay mind. The same thing might happen if the Minister of Transport and Minister of Mines would study the problem from other aspects than the one on which they have been steadfastly keeping their eyes, as though there was no possibility of there being any other. The Minister of Mines, states Mr. Garvin, recently described "the new use of coal" as our one ray of hope; and he went on to remark: "I have authority to say that the Government "are going to spare no money, no energy, and no effort "to bring this process to perfection." It is to be hoped in the national interests that they are going to do no such foolish thing. As a nation we cannot afford it. We want economy, and not a blind headlong rush into greater uneconomy.

As to the low-temperature coal carbonization process, it has a lower thermal efficiency than the high-temperature one; and the present state of the markets for the secondary products ought to be a warning to the visionaries that any pre-carbonization of coal by low temperatures would not reduce the generating costs of electricity, but would raise them to a figure which would make the electricity industry rock with anger against those who had, through stupidity and resistance to full inquiry, led it into such a mess. Our advice to publicists such as Mr. Garvin is that they should make certain they have the basic facts, and not accept the hypothetical assurances of any non-technical person who comes along with a superficially plausible tale, or persons interested in particular processes or plants. The same comments apply in major part to a paper read by Mr. Johnstone Wright, the Belfast Corporation Electrical Engineer, at a recent meeting of the local Association of Engineers. In the course of this, he stated that of the strictly technical problems of the future, so far as electricity production is concerned, the first is a more complete realization of the value of fuel. The change in the last few years in the value of fuel—not only measured in terms of currency, but in terms of human effort—has turned upside down all our previous conceptions. Mr. Wright thinks it is probable that the solution lies more in selective low-temperature carbonization with recovery of useful products. But we will give him credit for realizing the speculative side of the proposal; and the effect this would have in causing uncomfortable oscillations in the cost of generating electrical energy. The element of speculation is, in fact, formidable to Mr. Wright; and, in his opinion, might alarm investors and affect the facilities for raising capital. In view of this, he submits that an ideal distillation scheme is wanted—one which would enable the user to vary rapidly the classes of bye-products, so as to meet changing markets, and, to ensure success, one that would be financially safe, even if a large part of the products were used for power generation. It is something to find in one quarter a recognition of the element of speculation. Having got so far, Mr. Wright should explore the commercial aspects, and perchance he will find that the whole range of secondary products from coal carbonization has dropped considerably in market value, and that unfortunately simultaneously. In such circumstances, it is impossible to see how even the ideal system that he has adumbrated in his own mind would, through the varying of the products according to the state of the markets, ensure success. There can be no assurance of success. The position is altogether different with the high-temperature process, the gas therms from which have a large constant market at a much lower cost than low-temperature gas or electricity can offer.

It may be charged against us that we are prejudiced in favour of high-temperature carbonization, and, in the interests of the gas industry, of a better co-ordination of the utilization of our national fuel supplies. If there is prejudice, it is born of the knowledge of the economic advantages in comparison with the situations occupied by the various vague and unsubstantiated schemes which have been put forward. No one is asked to accept our statements without the fullest investigation. It is such investigation that the gas industry desires shall be made in the national interests before it is too late. If our publicists desire to take a hand in some really good work, it should be in urging such an inquiry, and not accepting as being of proved soundness and validity such ideas as are confidently put forward by Mr. Garvin, and as pointed to as directive by Mr. Wright. The days have passed for piecemeal treatment of such a highly important matter; the days are here when thoroughness and comprehensiveness should be showered upon the solution of the fuel, power, and heat problem of this country.

Wembley Opening.

The former announcement as to the opening of the British Empire Exhibition has been cancelled. The day is now fixed for Saturday, May 9; and the ceremony will be performed by the King, who will be accompanied by the Queen.

London Gas Price Advances.

As was foreshadowed at the recent annual meetings of the proprietors, the London Gas Companies have had to raise the price of gas. This has been absolutely essential, in view of the serious fall in the values of secondary products, and the higher wage payments. The necessity for an increase of price having arisen, it is good policy not to defer it, in view of the fact that, in the lighter months of the year, the consumers will feel the increase less than they would during the winter season. In the case of the Gas Light and Coke Company, the increase is from 8·6d. to 9·4d. per therm. The South Metropolitan Company have raised their charge from 8d. to 8¾d. per therm. The Commercial Gas Company's price has ascended from 8½d. to 9⅝d. The Wandsworth Company have advanced the differential prices ruling in their areas by ⅜d. per therm.

Industrial Rating.

Regarding the rating of industrial establishments, the gas industry will have much sympathy with the views of the Federation of British Industries which were at a recent interview laid before the Minister of Health. The basis of assessment at the present time differs as between area and area; and this is distinctly inequitable from the point of view of competition in different trades. The gradual extension of the assessment basis has also added to the burden of rates borne by industry. The recommendations of the Inter-Departmental Committee appear to propose to establish by Bill the present basis of assessment, with the proviso that only a proportion of process machinery is to be included for valuation purposes. To these recommendations the Federation are strongly opposed; mainly on these grounds: (1) Equity in comparison with other classes of rateable property; (2) equity between industries; and (3) uniformity. The Federation hold that uniformity can only be obtained by accepting the net rental value as the basis of valuation. To assess this rental value, they submit there should be taken into account only land, structure, and first motive power producing plant, and that this rental value should be adjudged taking into account the normal working hours of the particular industry concerned. In view of the great divergencies of practice in different factories for power purposes, the Federation suggest that the power plant should only be taken as far as the control of the first producing plant. Where energy is purchased from an outside source, there should be no assessment of the power plant unless a converter or transformer is used. It is, however, left open as to whether gas-engines should or should not be assessed where gas is purchased from an outside authority. The Federation are of opinion that the policy they recommend would be a distinct incentive to manufacturers to employ the most up-to-date plant, and to make the replacement of out-of-date plant a subject less to be feared than it is at present. This naturally would result in a general improvement of industrial efficiency.

The Factory Bill.

It is understood that the Government have decided that the Factory Bill shall not be deferred to next year, as formerly intended, but shall be introduced as early as possible after Easter. It is said that the measure contains about 140 clauses. Though largely a Consolidating Bill, it incorporates several new proposals, some of which are calculated to arouse considerable controversy.

Co-partnership Bill.

The Co-partnership Bill was recently introduced for second reading in the House of Commons; but there seemed to be little enthusiasm over it. Indeed, after the mover and seconder had spoken, the opponents—Labour-Socialists and an Arch-Communist—fired volleys of platitudes at it, with the result that the measure was talked out.

The Vauxhall Colliery Lesson.

A short time ago we referred to an interesting experiment which is being made by the miners at the Vauxhall Colliery, near Wrexham. It will be remembered that owing to output and costs and lower market values, the owners determined to shut down the pit; but the men are now proving that, if they choose to exert themselves, they can not only earn more money, but can convert a losing concern into a paying one. They entered into an agreement with the owners to work the pit rather than be thrown out of employment. The conditions included a guarantee that the men should bear any loss. To protect themselves, a guarantee fund has been raised by them. Some of the miners at other collieries have subscribed towards the fund; and the men have been encouraged by promises of contributions from other quarters. The fund, however, is purely for protection purposes; and it is hoped it will not be required. So far the men are perfectly contented. They are working full time; but their wages have already increased. Very few coal getters in the district are receiving the minimum wage of 9s. 6d. per day; but the week before last, the wages book of the Vauxhall men showed they were earning from 12s. to 18s. per day. The North Wales Miners' Association appear to be troubled as to the line of action they should adopt towards these members, who have dared to labour in a way which is to their personal advantage, but opposed to the policy of the Union. We can understand the Executive of the latter being disturbed by the proof that is being given as to the ability of the men to work to greater productivity, and so gain an increased rate of pay. The Executive of the Union proposed that the men should be expelled for three months; but they have gone on despite the excommunication threat. There is some uncertainty, too, as to the attitude over the matter of all the miners in the area, some of whom have gone so far, as already said, to subscribe to the guarantee fund. We like the sportsmanlike spirit that this shows; it throws into stronger relief the pernicious policy of the Union. No decision, however, has yet been arrived at as to Union membership of these men who are looking after themselves rather than be slaves to the policy of the obscurant Union rulers.

Synthetic Nitrogen.

In the House of Commons recently, questions have been asked as to the purchase from the Government of the nitrogen "factory" at Billingham by Messrs. Brunner, Mond, & Co., Ltd. The suggestion is that the terms were unduly advantageous to the firm. There is not the slightest foundation for this, judging from a letter from Colonel G. P. Pollitt, a Director of Synthetic Ammonia and Nitrates, Ltd. When taken over, the factory consisted of a number of fields, not drained, and only partially provided with roads and railways. Not a single building other than contractors' temporary huts and sheds for stores had been erected. The general stores on the site, the contractors' plant, the roads and railways, and the contracts entered into by the Government were finally agreed by the representatives of the firm and of the Disposals Board at £495,000. The Company have carried out to the full the wish of the Government that the synthetic nitrogen industry should be established in this country. As a consequence, it is claimed that not only have they largely increased the supply of fertilizers at less than pre-war prices in this country, but they have also rendered it independent of Chilian nitrate as the chief source of our national explosives supplies. It is added that anyone familiar with the precariousness of the position with regard to fixed nitrogen in the last war will realize that this achievement is of the highest national importance.

Poplar Wages Surcharges.

The Poplar Borough Council have had to climb down in connection with their extravagance in the payment of wages; and they are now in a serious dilemma. It will be remembered that the District Auditor made a surcharge of £5000 on members of the Council in respect of wage payments during 1921-22. The matter has been contested in the Courts; and the House of Lords has upheld the surcharge. Now the Council have been brought to their senses, and have resolved to consider the whole question with the view to bringing wages into conformity with the decisions of the Courts. As the same time an appeal has been made to the Ministry of Health, asking that the surcharges be remitted; the grounds being that the matter has been one of great difficulty, and one which was novel and of vital importance. It is also desired that the costs of the proceedings shall not be made the subject of a surcharge. It is evident, however, that the Council are unrepentant, as they say that, under protest and with great reluctance, they propose to consider the whole question of wages with the view

:o conforming with the decision. They plead that they are in i quandary owing to the fact that neither the Court nor the Auditor has stated what wages can be paid. Detailed consideration is therefore required; and they are prepared to promise there shall be no unnecessary delay. It should be easy enough for the Council to ascertain what is paid for similar work by councils who have not been surcharged. Anyway, the Poplar Council have now learned that ratepayers must be protected against the extravagance of partisan councillors.

PERSONAL.

Mr. J. Hood, Chief Technical Assistant to the Shrewsbury Gas Light Company, has been appointed Assistant Engineer and Works Manager to the Cheltenham Gas Light and Coke Company. Last year Mr. Hood was awarded a First-Class Diploma in Gas Engineering under the Education Scheme of the Institution of Gas Engineers; and he has since been elected a full member of the Institution.

Mr. F. Allen, B.Sc., has been appointed Assistant Engineer to the Bedford District Gas Company. Mr. Allen graduated at Leeds University in 1923, since when he has been assisting Mr. F. A. West, of the Newark Gas Company.

Mr. H. Taylor, formerly a member of the staff at the Central Laboratory of the Birmingham Gas Department, has taken up the position of Chief Chemist to the County Borough of Blackburn Gas Department.

Mr. W. G. S. Cranmer, Manager of the Willenhall Gas-Works, has been re-elected a member of the Short Heath Urban District Council.

Mr. Albert Whiteley (the Manager and Secretary of the Kirkburton Gas Light Company, Ltd., near Huddersfield), has been appointed a Director of the Shelley and Shepley Gas Light Company, Ltd., Shelley, near Huddersfield.

The Megiun Vertical Rotary Retort.

Mention is made by "Engineering" of the rotary low-temperature retort of the Megiun A.-G., at Butzbach, which, it is stated, differs from others chiefly in one respect. The retort is externally heated; but the vapours liberated collect in the central portion of the retort, where they are protected against over-heating by a double shell of steel and the coal under carbonization. The retort consists of a vertical drum rotating at a rapid rate within the setting. Inside this drum revolves a second drum, at a slower rate. The two drums are supported on the same vertical shaft. The outer surface of the inner drum is fitted with a helical conveyor fin, and the coal descends on this helix in the annular space between the two drums. Owing to the rapid rotation of the drum, the coal is thrown against this shell, which is exposed to the furnace flames, especially in the upper portion. The lower portion of the furnace is not heated. The inner shell is perforated, and the vapours liberated pass through the perforations into the inner space of the retort, which is much wider than the annular space. From this inner space, the vapours are withdrawn upward. Experiments which have been continued for several years in a small plant show, it is said, that a superior low-temperature tar is produced, fairly free from dust. The further product is a good semi-coke. Experiments have been made with various coals and lignites; and a point of interest is that coal dust and lignites high in earthy constituents, otherwise not amenable to retort treatment, have been carbonized.

Institution of Chemical Engineers.—At a meeting of the Institution to be held in the hall of the Chemical Society, Burlington House, Piccadilly, on Wednesday, April 22, a paper entitled "Continuous Distillation of Petroleum" will be presented by Mr. A. M. O'Brien, F.I.C., M.I.Chem.E. The President of the Institution (Sir Arthur Duckham, K.C.B.) will take the chair at 8 o'clock.

Eastern Counties Gas Managers' Association.—The President (Mr. F. A. West) will receive the members and guests at the Gas-works, Barnbygate, Newark, at 11.45 next Wednesday (April 22), on the occasion of the half-yearly meeting; and they will afterwards be entertained at luncheon by the Chairman and Directors of the Newark-on-Trent Gas Company, in the Clinton Arms Hotel, Market Place, at 1.30. At 2.45 the business meeting will take place in the hotel; the agenda including the President's Address and a paper by Mr. C. B. Donkin, associate member, on "Gas for Industry." In the evening there will be the annual dinner; and for the following day a drive has been arranged from Newark to the Chesterfield Works of Messrs. Bryan Donkin & Co., Ltd., where special furnaces to be described in the paper already referred to will be shown. The members will be the guests of the firm at luncheon.

ELECTRICITY SUPPLY MEMORANDA.

In the work of the Electrical Development Association, Mr. R. Hardie, of the Glasgow Corporation Electricity Department, has become quite a favourite person since electric cookers were let on hire in that city. In the

Cooker Hire Charges.

"Memoranda" last week we referred to his paper at the last (for the session) Salesmanship Conference in London. Since then he has been in Leeds lecturing at a local Salesmanship Conference. His subject on this occasion was "Electric Cooking Problems"—the same old problems, in a new dress of words. In his prefatory observations, the lecturer emphasized the fact that the questions of installation costs, hiring charges, and (most important) running costs, weigh very heavily with consumers in coming to a decision in regard to electric cooking. As to the hire charge, he stated that for the first year it was £1, and 10s. per annum afterwards; and this sum includes special wiring, which costs £2 10s., together with a kettle and kettle-board, which cost £1 10s. This brings the total capital outlay to approximately £16. It seems to us that, the capital outlay amounting to £16, the hiring charges will not liquidate the sum before the expiration of 31 years, to say nothing of interest and depreciation. There may be some explanation; but, as we read the reports of the lecture, the user pays £1 the first year, leaving £15 to be discharged at the rate of 10s. per annum thereafter. If this is so, then one can fairly say that the apparatus will be worn out or obsolete long before the capital has been wiped-out by the hire rates mentioned by Mr. Hardie. The Department, it appears, have been in a bit of a quandary regarding the correct hire charge to make. In the initial stages they imposed a charge of £2 per annum; and it is acknowledged that they had many grumbles in respect of this because in Glasgow gas cookers are installed free. Hence the reduction. Mr. Hardie also admits that, in spite of the attractive tariff, they have occasionally received complaints of excessive running costs, which, of course, he alleges are due to extravagant and improper use.

Satisfactory, and Yet Not So.

The lecturer proceeded to state with confidence that the modern electric cooker is satisfactory in the hands of the average careful operator, owing to the improvements which have been effected during the past three or four years. But as we read on, it is found that the hotplate, which is the largest absorber of electrical energy, is still in an unsatisfactory and inefficient state. How can there be complete satisfaction with this defect in a vital part? Mr. Hardie holds that the oven and the grill are both good features—in fact, like a good honest electrical salesman, he says that these features are superior to any competitive apparatus. But as to the hotplate, he says: Surely there is sufficient ability in the electrical ranks to provide one which will embody improvements suggested from time to time by experts! He goes further and suggests that the "E.D.A.," or the "I.M.E.A.," or the "B.E.A.M.A." might offer a substantial money prize to the producer of a cooker boiling-plate which would at once be speedy and indestructible; one condition being that the minimum efficiency shall be 50 to 60 p.ct. For many years the manufacturers of electric cookers have been trying their utmost to secure precisely what Mr. Hardie now advocates a prize should be offered for; and they have not succeeded. Had they done so, the indestructible and highly efficient boiling-plate would now be part of the ordinary electric cooker. There are many physical and other difficulties in this regard—difficulties due not only to the heating medium itself, but to the use to which the boiling-plates are put by householders. It is not an easy matter; and Mr. Hardie knows this quite well, otherwise we are confident that he would make a memorial for himself by producing the thing required. However, this gentleman, as we showed last week, is of a most ungenerous disposition, and cynical where gas is concerned. He seems to be particularly fond of trying to besmirch the gas cooker with all the calumny which prejudice can suggest, which is dangerous. In this particular lecture he says that the gas industry has taken thirty years to produce what it describes as the "perfect" cooker; and it gained its knowledge not only by workshop or laboratory tests, but by experience with apparatus under actual working conditions. In the interim, in spite of the "imperfect" apparatus, it has succeeded in building-up an enormous cooker business. If anything, that statement is (though unintentionally so) against Mr. Hardie himself, in view of the fact that, notwithstanding the "imperfections" of the gas-cooker, the electricity supply industry has not been able to build up an enormous cooking business. The public are evidently the better judges of the relative perfections or imperfections of the two systems of cooking; they certainly know on which side is to be found household economy in respect of money, time, and range of utility. Hence the 5½ million of gas cookers and grillers which are to be found in use in England, Wales, Scotland, and Ireland.

A Heavy Capital Expenditure.

Of course, one great obstacle to the development of the electric cooker is its very high price. Mr. Hardie points out that while a gas cooker costs about £4 the electric cooker costs £12 10s. We would add that the extent of the capabilities of a gas cooker which costs about £4 are a long way ahead of those of an electric cooker which costs £12 10s. It is admitted that it may be reasonably expected that the electric cooker will cost more than a gas cooker, but our Glasgow friend thinks that three times more is too much, and therefore a reduction of price is imperative. An important point is made in this connection. The capital expenditure involved in the hiring-out of electric cookers at such prices as those now ruling would be immense if the business developed in any substantial measure. In our opinion, such capital expenditure will be avoided by the limitations set on demand by the electric cooker itself. In Glasgow, for example, Mr. Hardie states they have at present on hire 1400 cookers which involved a capital expenditure of over £20,000. Our friend appears to have been shocked by what results from multiplying that figure by five, inasmuch as he describes it as "appalling." Multiplied by five, the number of cookers only becomes 7000; but the capital expenditure £100,000! Mr. Hardie thinks that little can be done in cheapening the cost of electric cookers unless a factory is provided and equipped for mass production. He is afraid that at present the majority of firms engaging in this class of output regard it as purely a side line.

Electric Cables and Street Explosions.

In the "Journal" for March 25 (p. 751), paragraphs appeared referring to two street explosions. The first related to an explosion at Notting Hill Gate, which sent into the air six electric light distributing boxes, and damaged about 300 ft. of pavement. The other explosion was at Acton, when four men were injured. The explosion wrecked the bars and blew out the windows of a public house. Regarding the latter uncomfortable incident, Mr. G. L. Jennings, of the Brentford Gas Company, in our issue for April 1, pointed out that this explosion was not in any way connected with the gas supplied by his Company. It was caused by the fusing of a long length of electric cable, which gasified some of the bitumen coating. The gas so generated was the cause of the trouble; coal gas not being in any way concerned. The unpleasantness with gas electrically generated from the bitumen coverings of cables is an old-standing one; and it was a fortunate thing for the gas industry when explosions up North and in the Midlands caused the identification of the real culprit in the matter. Prior to these occurrences, it was always charged to the gas supply that leakage of gas into electric cable culverts was the actual cause of street explosions. But now, as in this Acton case and in the Notting Hill Gate one, it is frequently possible definitely to prove that the electric cables themselves are solely responsible for these happenings. In the "Electrical Review," Mr. W. Love, writing on the Notting Hill Gate upheaval, alludes to the common assertion that such incidents are caused by leakage from adjacent gas-mains, and he says that no other cause has hitherto been suggested. Of course, in this he is totally mistaken. However, he advances another theory for some of these explosions. He says he is deliberately of opinion that they are attributable to electrolytic decomposition of water or humidity, and the ignition of the resultant gases by short circuit, &c. To this conclusion he has been led by the fact that such explosions are always extremely violent—a constant characteristic of the inevitably correct proportions of oxygen and hydrogen produced by electrolytic decomposition. On the other hand, an explosion of gas might occur with wide variations in the proportions of gas and air. Anything above or below the critical mixture considerably weakens the explosion which at its best or worst is mild in comparison with the violence of the absolutely correct mixture produced by electrolysis. To know the cause is the first step towards finding the remedy. We hope in the public interests the remedy will be found.

The "E.D.A."

The Electrical Development Association appear to be making somewhat slow progress in increasing the membership. To this opinion we are led by statistics which appear in the annual report of the Council of the "B.E.A.M.A." for last year. As a matter of fact, the net accretion in membership of the Development Association was only from 1166 to 1172 during the year. Of this number, municipal undertakings represent 100, companies 87, manufacturers 244, contractors 741; but some of the concerns have raised the amount of their annual subscription. It is also learned that, in addition to the ordinary revenue of the organization, nearly £25,000 was contributed last year by 264 supply undertakings towards the display organized by the Association at the British Empire Exhibition. The latter figures show that the administrations of a considerable number of supply undertakings refused to dip into their funds to help in the co-operative display at Wembley. We know too that prior to the Exhibition of last year, as well as during its course, there were several hints in the electrical Press regarding the difficulties that the Association had had in raising the sum necessary for making an effective display during the six months.

Local Exhibitions.

In the same report there is a reference to exhibition policy. The managements of electrical undertakings seem to be unanimous in the opinion that the manufacturers of electrical appliances have unlimited resources—financially, and in respect of spare goods. Before the question of exhibiting at Wembley last year was talked about, there had grown up in the electricity industry a large demand on the part of undertakings for local exhibitions, with the view of stimulating the business of their enterprises. These exhibitions were promoted by both municipal and private concerns. They overlapped as to subject, and there was conflict in date—in fact, there was no system of any sort in their organization. Naturally, this created a great deal of perplexity among those firms who would wish to be of assistance in such matters, but who were debarred by the real complexity of conditions from doing what they would otherwise have done. The report before us states that even before Wembley closed its doors last October, this movement had been revived, and had since grown almost to an epidemic. It is said that the taking a hand in such exhibitions by members of the "B.E.A.M.A." is, by a clever system of "snowballing," rendered almost an obligation upon them. But the Council of the Association now feel that the whole position will have to be reviewed. They are wise in this. The appliance manufacturers connected with the gas industry would be equally averse to being assailed in the same manner—amounting almost to persecution. Certainly what is described is an unfair drain upon the resources of the various electrical firms.

April 1.

On this date "Electrical Industries" published a paragraph, "Gas Refused." In the course of it the remark was made: "If we were so inclined, we might call the attention of the 'Memoranda' contributor of the 'Gas Journal' to this awkward bit of news, and ask him to explain it away with his pretty wit; but we do not like to ruffle anybody unduly—so we won't mention it." The writer of "Gossip" in our contemporary need not be afraid of hurting the feelings of the writer of the "Memoranda," and particularly in connection with the matter in hand. It refers to the ventilation of a certain section of the offices of the Glasgow Corporation Gas Department, and to a proposal to instal electric lighting in it. We need not re-enter into this matter, in view of the fact that, on the same date as our contemporary appeared with its invertebrate paragraph, the position of this question was explained in two paragraphs in the "Memoranda" under the headings of "Circulating Falsehood" and the "Present Position." If the writer of "Gossip" will refer to those paragraphs, he will obtain some useful enlightenment.

Gaseous Fuels for Furnace Heating.

In a recent paper before a meeting of the West of Scotland Iron and Steel Institute by Prof. R. V. Wheeler, the author discusses the relative merits of carbon monoxide and hydrogen for furnace heating. Though both have the same calorific value, a carbon-monoxide flame radiates nearly 2½ times as much heat as a hydrogen flame burning the same volume of gas. On this score alone, therefore, a high content of carbon monoxide is preferable to a high content of hydrogen in a producer gas for furnace work. The rates of burning of hydrogen and of carbon monoxide in contact with heated surfaces are widely different. Surface combustion, though it can be usefully promoted in certain circumstances, may prove deleterious in an ordinary furnace, in view of the fact that the production of local high temperatures is harmful to the furnace walls, and materially shortens their life. Hydrogen when mixed with air is far more susceptible than carbon monoxide to the catalytic effect of heated surfaces. For this reason the destruction of brickwork in a steel-melting furnace is more rapid, and the wastage of material in a reheating furnace is greater, when the producer gas used contains a high proportion of hydrogen. With regard to the use of coke-oven gas for furnace heating, the methane and, to a lesser extent, the carbon monoxide stabilize the flame; and the hydrogen and carbon monoxide, by reason of their wide limits of inflammability, ensure the "adaptability" of the gaseous fuel. The chief advantage claimed for coke-oven gas is that the working temperature of the furnace can be increased so that about 25 p.ct. increased output can be obtained; while difficulties encountered in its use are the tendency of the flame to rise to the furnace crown and fuse the brickwork (because of its low density compared with that of producer gas), and the low luminosity of the flame (owing to the freedom of the gas from tarry vapours) which renders difficult observation of the conditions in the furnace. Both difficulties can be overcome by using tar in addition to the gas; and, since the use of coke-oven bye-products in this manner dispenses with gas producers and simplifies the construction of the furnaces, no doubt the practice will spread.

EFFICIENCY IN GAS-WORKS.

A New Point of View.

By "Psychologist."

The word "efficiency," when used in relation to the working of gas undertakings, is usually associated with technical advances, and in general little heed is paid to what may be termed the human side of the question. Large sums of money—quite rightly—are spent annually on purely scientific research, but too little effort is made to increase efficiency by studying the conditions under which the gasworkers do their work. From time to time, of course, improvements are made in working methods in (say) the repair shops of the larger concerns, but these improvements are casual, and are not based on a real appreciation of the existing conditions. It is only by intimate contact with, and careful examination of, the particular work and the particular circumstances that the defects of an existing system can be realized; and the management, who perhaps only spend a few minutes in the shops each day, cannot grasp them. It is impossible for them to discover the means by which working conditions can, in small ways, be so changed as to increase the efficiency and happiness of the worker, and, through this, the output of work per man.

Those Little Things.

What are regarded as the trivialities of life are often, in the mass, of far more importance than the events which appear outstanding; and so it is in work—the minor and so-called unimportant details are in the aggregate of major consequence. The scientific outlook has resulted in amazing progress in every field of the gas industry's activities; and it is suggested—and the suggestion is based on results—that industrial psychology can do much to increase efficiency in other directions in all these fields. In this short article it will suffice to take two examples of the application of psychology to the gas industry—first, in a stove and meter repair shop; secondly, in the selection of suitable workers for the industry.

National Institute of Industrial Psychology.

The work is being carried out by the National Institute of Industrial Psychology. The first thing they do is to send an investigator to the job, so that he may find out exactly what are the physical and mental requirements of the work. No recommendation is made to the management until the investigator has spent at least a month in the particular shop which is under test, and has thus become intimately acquainted with the work and the prevailing conditions. In the meter repair shop of a large gas company, it was found that the handles of the soldering irons were two inches too long—a small point to the management, certainly; but not a triviality to the man who has to use the tools every day of his working life. This defect was rectified, and the results were amazing. Then it was discovered that the workers were much less tired at the end of a day's work if they were provided with wooden footboards which allowed free circulation of air. It was also found that by attention to efficient lagging, the workers were far less affected by the heat from the soldering-iron stoves. In the stove repairing shop similar small changes were effected, or new apparatus introduced. Brushes, tools, devices for lifting, and many other points were examined closely, and improvements were made. These improvements, in themselves small, were, taken together, of first-rate importance; not only did they increase the efficiency and output of the shops, but also, by relieving discomfort and doing away with unnecessary expenditure of energy, made the workers much happier.

Square Pegs for Square Holes.

In any industrial concern it is easy to appreciate the difference in value between an efficient and an inefficient worker. It is not as though the inefficient worker were merely a nuisance to himself; he is a nuisance to everyone around him, and lowers the working rate of his associates. Two or three men who are obviously unfitted for their work can often spread discontent throughout a shop. The object of the National Institute of Industrial Psychology is to assist in the choice of the right type of man for a particular job. First of all the mental and physical requirements of the job are found—in some work, for example, manual dexterity and keen eyesight are demanded. Then apprentices, &c., are chosen who have the necessary qualifications. This selection is much better than the ordinary procedure of examination and interview. Psychological investigations have been carried out in polytechnics in London on tests for the admission of apprentices to the various branches of engineering work; and these are now being applied practically and with success in two large Manchester works. Definite occupations require well-defined qualities in the youth who intends to take up the work. A meter inspector, for example, should have a memory for figures. In the case of a draughtsman, apart from the technique and conventions of drawing, the ability of "seeing into the solid" is essential for this type of worker. The same ability is a necessary factor in the sheet-metal trades. There the men start from the flat to work the metal to the three dimensional. True, they may work to templates, but these should be for testing and correcting in the majority of cases. The work in the main depends on a particular ability of space perception. So one could continue; but sufficient has been said to indicate that increase of efficiency in the gas industry does not depend wholly on technical considerations, and that probably the incorporation of psychology will form the starting point of new advances.

COAL AND CARBONIZATION.

A meeting of the Birmingham and Midland Section of the Society of Chemical Industry was held on Tuesday, March 31, at the University of Birmingham. Prof. G. T. Morgan (Chemistry Department, Birmingham University) presided, and there was a good attendance of chemists and others interested in the chemistry of coal, oils, and other minerals.

Dr. R. Lessing read a paper on "The Inorganic Constituents of Coal." He pointed out that no less than 25 million tons of non-combustible material are annually distributed in Great Britain. Leaving out of consideration the potential value of iron, sulphur, and building materials, which may in the future be recovered from the coal minerals, the inorganic constituents are worse than useless, and involve the nation in a non-productive expenditure of millions of pounds, absorbing, for example, 10 to 15 p.ct. of the mineral traffic of the country.

Dr. Lessing proceeded to classify the mineral constituents according to their origin from plant material, decomposed rock, saline deposits, before, during, and after coal formation, and their products of interaction. He referred to the work of Dr. Marie C. Stopes on the constitution of coal, and to his own work, as well as that of Sinnatt and others, on the mineral matter in coal. He showed from detailed analyses that clarain and vitrain contain only original plant ash, and that durain is a mixture of small plant entities such as spores and cuticles. He showed that the largest proportion of ash was derived from the roof, floor, and dirt-bands of coal seams, and that the inherent ash of pure coal did not exceed 3 p.ct.

The lecturer then described and demonstrated experimentally his method of separating coal quantitatively into its ingredients by his combined elutriation and float-and-sink method. He pointed out that this method afforded a means of coal classification on a rational basis. He insisted that the ash content should be allowed for in any method of classification. Dr. Lessing proceeded to demonstrate the significance of his experimental results for practical coal problems. He pointed out that the elucidation of the morphological structure and chemical constitution of coal was a first condition for success in solving these problems.

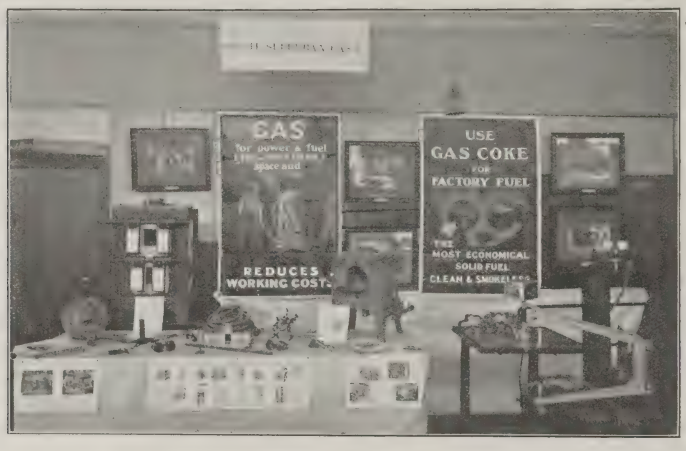
He described his method of mining coal chemically with the aid of sulphur dioxide in substitution for explosives, and referred to the trials carried out in this country and America which had already demonstrated that this reagent could be used underground with absolute safety and without discomfort to the workers. He then showed the importance of the inorganic constituents in the preparation of coal for the market, particularly in coal washing, and foreshadowed an extension of the scope of coal refining beyond the reduction of the ash content to the commercial separation of grades for definite purposes—such as coking, gas-making, smokeless-fuel producing, boiler firing, and domestic use. He referred to the difficulties of commercial sampling, due to the uneven distribution of mineral matter in coal, both as regards percentage and chemical composition. The effect of the ash on the combustion process, its fusibility, and physical properties were next dealt with, and the lecturer sounded a warning that, for the successful development of powdered fuel firing, reduction of the ash must be effected, so as not to substitute a dust menace for the vanishing smoke nuisance.

Dr. Lessing then gave an account of his work on the influence of catalysts on carbonization. With the aid of lantern slides, the results from experiments showing the effect of inorganic addition to sugar, cellulose, and coal were demonstrated; and Dr. Lessing indicated that the present empirical processes of carbonization will have to be modified or replaced by methods allowing the carbonizing equilibrium to be influenced at will towards solid, liquid, or gaseous products.

The lecture was illustrated by experiments, and a great number of specimens of coal ingredients and ashes showing the distribution of mineral matter.

An Invitation.—Members of the Institution of Gas Engineers are invited to attend a meeting on Wednesday, May 6, at 6 p.m., at the Institution of Civil Engineers, when Mr. J. Carnaghan will introduce for discussion "A Standard Code for Tabulating the Results of a Heavy Oil Engine Trial." The chair will be taken by Captain H. Riall Sankey, C.B., C.B.E., Chairman of the Special Committee tabulating the results of Heat-Engine Trials.

CO-OPERATIVE DISPLAY BY JUNIOR ENGINEERS.



SMOKE ABATEMENT.

COAL CONSERVATION.

A good idea comes to us from Dartford, which may be suggestive, from the educational point of view, to junior engineers engaged in different branches of the profession. Organized by the North Kent Section of the Institution of Junior Engineers, a very successful engineering exhibition was held on a recent Saturday, in the dining-hall at the works of Messrs. J. & E. Hall, Ltd., at Dartford. A number of firms, including the South Suburban Gas Company, entered heartily into the co-operative display, and made interesting contributions, as will be indicated presently. Over these the junior engineers in the different branches of the profession lingered, and sought much information from their fellows.

The exhibition was opened by Mr. H. J. Ward, Chairman of Messrs. J. & E. Hall, Ltd. In the course of his remarks, he made it clear that in his opinion the education of the younger members of the engineering profession should receive most careful attention, and that every opportunity should be given them to improve their knowledge, as the future of the engineering industry depended upon the juniors. In his view local exhibitions of this kind were a very great help in stimulating the interest which is so necessary. He also spoke of the loss of British orders to foreign shipyards, but stated that he felt convinced that brighter days were in view.

The following firms contributed exhibits:

Messrs. J. & E. Hall, Ltd.	Refrigerating machinery, machine tools, "Todd" oil fuel burners, &c.
Messrs. Vickers, Ltd. (Dartford)	Shells, bomb carrier for aeroplane, &c.
Messrs. Vickers, Ltd. (Erith)	Machine guns, high-speed twist drills, &c.
Messrs. Vickers, Ltd. (Crayford)	Aero engine (9 cylinder BR), gun parts, &c.
Messrs. Vickers, Ltd. (Creek Works) ...	Specimens of ply wood.
Messrs. Mitchell Bearings, Ltd.	Ball bearings, &c.
Messrs. Heath, Ltd. ...	Optical and surveying instruments.
Messrs. Walker Crosweller	Thermometers, CO_2 recorders, &c.
Messrs. J. C. Beadle ...	Wireless apparatus.
Messrs. Fraser & Chalmers	Turbine parts.
Messrs. Elliott Bros. (London)	Electrical apparatus, voltmeters, &c.
Messrs. Aveling & Porter	Steam steering engine of the rotary-valve type.
Captain J. C. De Wardt	Wireless apparatus.
Marconi & Western Electric Company ...	Wireless apparatus.
Westinghouse Morse Chain Company ...	Model chain drive, &c.
The Swedish General Electric Company ...	Single-phase electric motor.
Pneumatic Plate Tightener Sales Company	Plate tightening gear.
Higham Engineering Company	Speed reduction gear.
Messrs. Johnson & Phillips	Switch boards.
Messrs. Callanders Cable Company ...	Electric cables and insulators.
Messrs. Pitter Gauge Company (Woolwich)	Gauges.
South Suburban Gas Company	Smoke abatement, furnaces, and oxy-coal gas cutting.

The Gas Company's exhibit comprised a stand dealing with smoke abatement and conservation of coal; the exhibits being supplied by the British Commercial Gas Association. The furnaces shown were supplied by Radiation Limited and Messrs. Fletcher Russell & Co. They included open-oven, high-speed steel, and muffle furnaces. There were also shown the Keith-Blackman method of mixture control, and Messrs. Hancocks' oxy-coal gas cutting and welding plant. Demonstrations were given on these, in which keen interest was taken. This exhibit was organized by, and under the charge of, Mr. E. L. Oughton, the Sales Superintendent of the South Suburban Gas Company.

SPENT OXIDE AND SPENT OXIDE BURNERS.

One of a series of papers submitted at a joint meeting on April 7 of the Chemical Engineering Group and the Birmingham Section of the Society of Chemical Industry, was by Mr. P. Parrish, A.I.C., M.I.Chem.E., on "The Combustion of Sulphur Containing Materials in Hand and Mechanical Burners."

The author said there can be no doubt that burners which admit of a continuous feed of sulphur, either in granular form or as molten sulphur, are to be desired from all points of view. Labour costs are reduced appreciably, burner gases of any concentration from 5 to 15 p.ct. can be obtained with uniformity, and the plant to which the burner or set of burners is attached can be operated with clock-like regularity. The efficiency of combustion exceeds 99·5 p.ct. One need not hesitate to instal mechanical sulphur burners, because there is no dust problem such as arises when spent oxide and pyrites are the raw materials. Although the initial cost of hand burners is somewhat less than mechanical burners, labour expenses are heavier, and the same uniformity of conditions cannot be maintained. For oleum plants combustion in mechanical burners is ideal from several points of view.

It is interesting to note that increasing quantities of brimstone are being used in this country, as is revealed by the following figures, which also show the relative importance of the other two principal sources of sulphur dioxide.

Sulphur Containing Materials Used in the United Kingdom.

	1923.		1923-24.
Pyrites	800,000	..	350,000
Spent oxide	110,000	..	148,000
Sulphur	3,000	..	66,000

The table given above indicates that the quantity of spent oxide used in this country has increased by approximately 35 p.ct. during the last decade.

Spent oxide is a complex mixture of a large number of bodies and contains varying quantities of moisture, tar, sulphur, and ferrocyanides. The following analysis, taken from "Cyanogen Compounds," by H. E. Williams, affords an idea of the complexity of the material:

Analysis of Spent Oxide.

	P.Ct.
Free sulphur	44·70
Moisture	17·88
Ferric monohydrate	5·26
Ferrous monohydrate	0·25
Basic ferric sulphate	1·25
Ferric ammonium ferrocyanide	2·80
Ferrosoferric ammonium ferrocyanide	2·50
Ferric pyridic ferrocyanide	1·20
Organic matter, peat fibre	4·68
Tar	1·21
Silica	1·05
Naphthalene	0·72
Pyridine sulphate	0·77
Ammonium sulphate	2·05
Calcium sulphate	0·12
Ferrous sulphate	0·02
Ammonium thiocyanate	1·30
Sulphur otherwise combined	1·33
Organic matter soluble in alkalis (humus)	1·54
Combined water and loss (by diff.)	2·36
	100·00

It is not economical to deal with spent oxide containing less than 40 p.ct. of sulphur. Indeed, buyers usually specify a minimum content as 45 p.ct. of sulphur, and not more than 10 to 12 p.ct. of moisture. Large quantities of material are available containing 50 to 55 p.ct. of tar-free sulphur.

Purification of Coke-Quenching Water.

Quoting from a contemporary, in the section dealing with progress in gas technology, the "American Gas Journal" says that water from coke-quenching apparatus contains notable quantities of hydrogen sulphide and hydrocyanic acid, and may be purified by passing through rough filters containing coke, which retain 85 p.ct. of the acids present. Final treatment with concentrated bleaching powder solution, to which sodium carbonate has been added, is recommended. The amount of bleaching powder required may be determined by adding 3 or 4 drops of a sulphuric acid solution of indigo-carmine to 200 c.c. of the water, and titrating with alkali hypochlorite solution until the blue colour disappears.

Midland Association of Gas Engineers and Managers.—The spring general meeting of the Association will be held at Oxford on Thursday, May 7.

Institution of Gas Engineers.—The Right Hon. Sir Philip Cunliffe-Lister, K.B.E., M.C., M.P., President of the Board of Trade, has accepted an invitation to luncheon with the Institution of Gas Engineers, at the Royal Automobile Club, on Wednesday, June 10 next.

NORTH BRITISH ASSOCIATION OF GAS MANAGERS.

The portion of the proceedings at the Spring Meeting of the Association in Edinburgh which was given in last week's "Journal" included two papers on the subject of maintenance —one by Mr. J. W. Napier and the other by Mr. George Keillor. Interposed between these was an address by Mr. J. W. M'Lusky, of Glasgow, on the same subject. A report of this follows.

MR. M'LUSKY ON MAINTENANCE.

Mr. M'Lusky said many gas managers to-day were losing business, and many were destined to lose business, because they had not yet realized that they were not doing half enough for the gas consumer. Generally speaking, the conditions found in the trial district in Glasgow were, in a more or less degree, applicable to the other districts. Whether or not it was from fear of being charged excessively for repairs to gas appliances and piping, some consumers seemed quite content to jog along with any makeshift. This question of makeshift fittings had been brought home to them very forcibly in Glasgow as the outcome of practical experience. Frankly, they did not know anything like one-half of the situation until they went out in the city to investigate and explore. Indeed, he was so impressed with what had been discovered that he wanted to ask his brother gas managers if they were familiar with the actual conditions in their own particular districts. Just by way of challenge, he desired to ask them how much more they knew about each house of their own district since last September, when he submitted a report as to what was then being done in Glasgow.

Going over some of the districts that were being maintained, and seeing the condition of piping—especially in the poorer and business parts of the city—one did not really wonder at Mr. Butterfield's warning in his report to the Board of Trade. Indeed, in order to emphasize this point, he had that day brought with him a few typical examples of what had been discovered. In a large factory using high-pressure gas, which was visited in the course of maintenance, complaint was made of very poor lighting and big gas accounts. The complaint of poor lighting was justifiable from the illumination provided—scarcely one burner was in proper order—and the firm were considering the question of changing over to another form of lighting. Maintenance fitters were soon on the job; and when the overhaul had been completed, the remark was made that the firm had not had such splendid lighting for years. The trouble in this case was that whoever had the work of annually overhauling the system did not seem to understand the type of burner, and in almost every case the injector hole had been enlarged to nearly six times its original diameter. For the inspection of his colleagues, he had brought with him a specimen of the injector used. That was only one instance of trouble with high-pressure gas. So far, in Glasgow, they had dealt with fifteen installations; and the results had been satisfactory.

Then he proposed exhibiting at this stage a piece of compo piping with about a foot of red indiarubber tubing tied to it. This was cut from a gas supply to a bracket in a bedroom where an old lady had been lying ill for years. It was found behind the window-shutter, where the supply pipe was running. The old lady said she always noticed a smell of gas. There was a bad leak; and the patient had certainly little chance of recovering while this piping was in use. Then he produced another contraption which was supplying a gas ring. It was a piece of compo piping to which was attached a bit of asbestos and rubber tubing, on which a Glasgow Gas Department crane was fixed. There was connected to this again a piece of flexible metallic tubing. Again, there was a specimen of a ¼-in. crane fixed to a piece of ⅜-in. compo piping by means of a cloth wrapping. These, he might point out for the information of the meeting, were only a few cases out of hundreds dealt with.

Proceeding, Mr. M'Lusky explained that between the month of June last and the end of February of the present year—during two months of that period maintenance was suspended —no fewer than 2300 consumers in the city of Glasgow were requested by maintenance fitters to call-in plumbers to deal with escapes of gas in private pipes. When a maintenance fitter found an escape of gas in private piping, he requested the consumer to call-in a plumber. At the same time he recorded this fact on a card provided for the purpose. The arrangement was that the inspector should call on the consumer within a week, and inquire if the escape had been duly attended to. If not, an appeal was again made to the consumer to summon a private plumber.

The radiator, though one of the most serviceable gas-heating appliances, was also one which had more abusive language showered on it than any other gas-heating agent; and yet the appliance was not to blame. In Glasgow their experience of radiators which had been fitted by maintenance men was that in nearly every case the apparatus had been entirely neglected. Some of them were even allowed to burn day after day without having a drop of water added. Of course, this sort of thing was bound to result in defective loops and inoperative

diaphragms. The automatic check action regulating the gas supply was rendered useless, with the result that big gas accounts were incurred. In Glasgow all hired radiators were thoroughly overhauled a year ago, and when met with during maintenance private radiators had been dealt with. During the past winter, in order to ensure that these appliances were efficient, a squad of men had been constantly employed watering and reporting defects, with the result that this most useful appliance had come into its own. The piece of sheet iron, shaped like a diaphragm, which he held in his hand, was what they had met with repeatedly in radiators. Leather and zinc were also found in use. The poor appliance was often blamed by the consumer, and yet the private tradesman had rendered his account and drawn his money for repairing it A small piece of glass tube which he exhibited represented part of an alleged gauge glass tube from a radiator. It was a piece of glass tube for a baby's feeding bottle. Gas fires of antiquated design were met with regularly; and it was only by a system of maintenance that consumers could be shown the disadvantages of their use. Old-type gas fires were, therefore, gradually being eliminated.

In regard to gas lighting burners, fitters and inspectors alike reported on the general satisfaction of consumers once lighting burners had been overhauled. Of course, in certain cases, burners were past useful service and repair, and sometimes the service of the maintenance fitter did not show any improvement. Maintenance had, however, brought before them in Glasgow the fact that, had the system been in vogue ten or fifteen years ago, they would to-day be counting among their lighting consumers many who introduced other lighting agents because of unsatisfactory illumination from their gas burners. To-day, in Glasgow, they were holding consumers who, but for the introduction of the maintenance service, would have been lost to the industry. They realized, when on maintenance, that every factory, workshop, hall, church, school, and public institution had not gone over to electricity; and by their efforts they expected to see gas retained wherever it was now used. It might be said that it was a costly business to replace globes and gas mantles broken by maintenance fitters; but the experience in Glasgow showed that it represented a small item. The number of lighting appliances overhauled between June, 1924, and January, 1925, was 317,845. During this period, the number of mantles and globes broken and replaced was: Gas mantles, 449, equal to 0·14 p.ct. of burners; and globes, 52, equal to 0·016 p.ct. of burners. Further experience had shown that maintenance fitters made good salesmen—from June, 1924, to January, 1925, no fewer than 2631 orders were taken for cooking, heating, and lighting appliances.

Mr. M'Lusky said that, on the question of expenditure, he was now in a position to give some interesting figures. When he reported first of all to his Committee on the Glasgow trial scheme, the figure of 1¾d. per 1000 c.ft. was mentioned. He was told that it could not be done for that, but eventually he was tied-down to 1¾d. Of course, it might be said that officials could produce figures to prove anything; but he would remind them that a balance-sheet was, after all, a balance-sheet. Experience showed that, after a certain period, they were able to report to the Committee that the cost was about 1¾d. per 1000 c.ft. The latest figures, however, revealed the cost as being 0·592d., or just over a halfpenny, per 1000 c.ft. Sometimes he did feel he was a brave man, and imagined he could start a good business in Scotland, and actually make a fortune, if he set out to maintain gas appliances at 1d. per 1000 c.ft. If he spent a halfpenny to make a halfpenny, this surely was good business. The cost per appliance for labour was 4·46d.; for material, 1d.; and overhead charges, 1·58d.—making 7·04d. per appliance. The details applicable to the cost per 1000 c.ft. were: Labour, 0·375d.; material, 0·084d.; and overhead charges, 0·133d.—giving a total of 0·592d. Applicable to the cost per therm made, the details were: Labour, 0·080d.; material, 0·018d.; and overhead charges, 0·028d.—a total of 0·126d.

These were marvellous figures, and the gas industry in Scotland had to admit it. In Glasgow they estimated that they had 1,250,000 appliances contained in 213,447 premises. They were at the moment maintaining 995,038 burners and appliances. In September last he reported that there were being maintained 410,000 appliances, so that in the past six months they had increased 140 p.ct. By so doing, they had reduced the expenditure from 1¾d. per 1000 c.ft. to 0·592d. In these figures he thought there was sufficient to show that, the bigger the maintenance scheme became, the cheaper it got. If fitters broke mantles or globes in the course of their examination, these were replaced. Since the Glasgow scheme was inaugurated, the percentage of broken mantles was 0·14, and the percentage of broken globes 0·016.

In conclusion, Mr. M'Lusky urged upon every member of the Scottish gas industry the importance of bringing this question of maintenance before company and corporation in some shape or form. If it was not practicable to get a whole town mapped-out on a scheme of maintenance, it might be feasible to experiment on a particular area or on a municipal ward. Something, however, ought to be done to drive home the thin end of the wedge, and there should be a general insistence on the policy that the gas industry in the future was not going to proceed on the old lines.

[The report of the ensuing discussion will be published next week.]

CAUSE OF LONDON FOGS.

A paper on "Modern Atmospheric Conditions," with special reference to London, was read recently before the Royal Society of Arts by Dr. J. S. Owens (Superintendent to the Advisory Committee on Atmospheric Pollution, Air Ministry), in which he advanced a new explanation of the cause of smoke fogs. He pointed out that during a thick smoke haze, and assuming an upper limit of 300 to 400 ft., there would be something like 200 to 250 tons of soot suspended over London. Further, the whole of this soot can be produced in about three hours by the fires lighted on a winter's morning. Thus, if Nature's provision for scavenging fails for a few hours, there is ample material for a dense smoke haze. The popular conception of such a condition in London is that there must first be a water fog, and that the globules of water are condensed around smoke particles, while the outer surface of such globules becomes coated with a film of tarry oil, which is supposed to account for their failure to disappear by evaporation, although the air may not be saturated. This, Dr. Owens believes, is an entire misconception; and therefore he put forward, as a more satisfactory explanation, and more in accordance with the facts, the theory that the "London Particular" is caused by a more or less complete replacement of water particles by smoke particles; the water droplets being partially evaporated by the higher temperature, and their place taken by smoke. In support of this view, he quoted various observations; adding that the bearing of this contention upon prevention is evident, since one is driven to the conclusion that, if smoke were not supplied to take the place of the water, London would be more free from fog than its surroundings.

THE HONLEY SPIRAL-GUIDED HOLDER.

PRESENT AT THE INAUGURATION

In last week's "Journal" a report was given of the proceedings at the inauguration of the spiral-guided gasholder at Honley. The above photograph of those present at the official "turning-on" of the gas by the Chairman of the District Council (Mr. G. T. Oldham, J.P.) came to hand too late to include with the report.

ELECTRIC POWER PLANT FOR GAS-WORKS.

Operating Dynamos in Parallel.

By Hugh P. Vowles, M.I.Mech.E., M.A.Min.E.E.

Introductory.

The writer has had twenty-five years' experience in the manufacture, installation, and operation of electric power plant, including several years on a large gas-works. These notes have been compiled in the hope that they will provide some guidance for those who, faced with the question of installing such plant, have had little time or opportunity to acquire the knowledge necessary to ensure the work being carried out satisfactorily. Let it be stated at once that it is not sufficient to rely entirely upon power plant contractors for guidance. The reasons for this statement will be made clear.

A greater diversity of technical knowledge is required on a gas-works than perhaps in any other branch of the engineering profession. It is necessary to have not only civil and mechanical engineering knowledge; one must be something of a chemist as well. It is only natural, therefore, that, with such a wide range of knowledge already required, many gas-works engineers should feel the need of enlightenment concerning the problems peculiar to electrical power plant. They realize that electricity will be used more and more on modern gas-works for such purposes as the operation of retort stoking machinery and telphers, and the driving of exhausters, scrubbers, pumps, and other plant. The difficulty is to select just that portion of electrical engineering data which will meet their needs without involving an exhaustive study, taking up time which cannot well be spared from other matters. To meet this requirement, the writer proposes to deal only with those electrical details which are of immediate practical gas-works interest. A bare knowledge of elementary electrical principles will be assumed, but beyond this the ground will be covered as fully as the scope of a necessarily brief article allows.

It may be noted here that, so long as only one generating unit is installed, the procedure to be adopted is simple. Given a reliable contractor, little difficulty need be anticipated. It is when further units have to be installed, and the works engineer wishes to be independent of any particular contractor, that his troubles are likely to begin if knowledge is lacking.

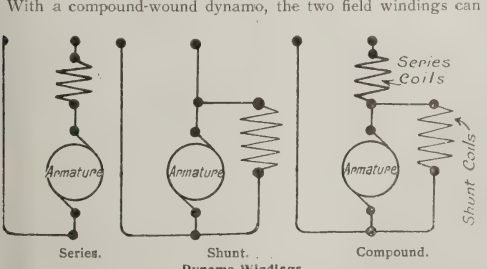
The only type of electric generating plant suitable for the average gas-works is the direct-current, compound-wound dynamo, driven either by steam or gas engine. In order that efficiency or economy shall not be sacrificed, such dynamos must be operated "in parallel." It will be convenient to lead up to a consideration of parallel operation with a few definitions.

Definitions.

Electric windings (as on a dynamo) are said to be "in series" when the end of one is electrically connected to the beginning of another, so as to form one continuous path for an electric current. Such windings are said to be "in parallel" when they provide two or more branch paths for an electric current; the current dividing and afterwards re-uniting at the point where the branches meet. Any branch which serves as a by-pass to another is called a "shunt."

There are three methods of winding direct-current dynamos—"series," "shunt," and "compound." A series-wound dynamo is one in which the field winding is in series with the armature winding and the main external circuit. A shunt-wound dynamo is one in which the field winding forms a by-pass or shunt to the main circuit. A compound-wound dynamo is one in which there are two sets of field windings, one in series with, and the other forming a shunt to, the main circuit.

With a series-wound dynamo running at constant speed, the voltage rises as the current output increases. With a shunt-wound dynamo, the voltage drops as the current increases. With a compound-wound dynamo, the two field windings can



Dynamo Windings.

be proportioned so as to compensate for each other, ensuring constant voltage at all loads, providing speed is constant. Such a dynamo is said to be "level-compounded."

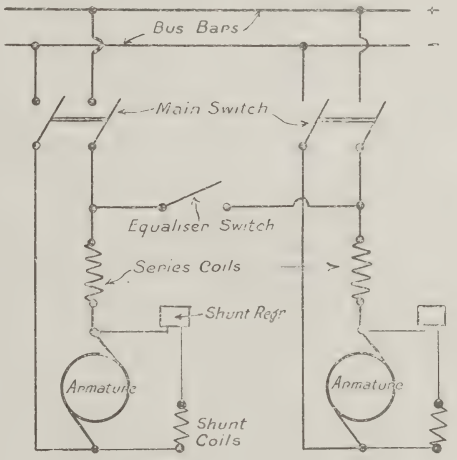
Although constant voltage at all loads is the ideal for normal conditions, some makers design their dynamo windings so as to give a slight rise in voltage, and other makers so as to give a slight drop in voltage, as the load increases. The one design of dynamo is said to be "over-compounded," and the other "under-compounded."

Compound-wound dynamos which differ thus in the degree of compounding will not run satisfactorily in parallel. "Running in parallel" implies that the dynamos are electrically connected by joining like terminals to form a common positive and a common negative terminal. This arrangement results in a combined voltage which is the same as that of any one machine; but the current available at the common pair of terminals is equal to the sum of the individual capacities of all the machines so connected.

Parallel Running.

Dynamos being designed to give greatest efficiency under full-load conditions, full economy of operation can only be obtained when each dynamo is worked as much as possible at its maximum output. If, instead of running in parallel, each dynamo feeds separate sections of a gas-works without electric interconnection, it is possible that several dynamos will each be running only partially loaded. There may not be sufficient load on any one circuit to load its particular dynamo fully. This means inefficient operation, while standing charges are the same for both efficient and inefficient operation. If, on the other hand, all dynamos are connected in parallel, then one may be started-up and fully loaded from any or all of the external circuits. If the total load increases, another dynamo can be switched in, and so on; no dynamos being used until those already running are fully loaded, and therefore working at maximum efficiency.

The ratio of the actual electric energy consumed to that which would be consumed with a continuous maximum demand is called the "load factor." A 100 p.ct. load factor represents maximum efficiency; and the economy to be secured by parallel running may be illustrated by the statement that in the case of



Compound Dynamos in Parallel.

small electric generating sets (say, 50 to 100 kw. capacity), the relative costs per kilowatt per hour at 100 and 25 p.ct. load factors are approximately in the proportion of 100 to 260.

Plant Specification.

It will be clear from the foregoing that when supplementary generating sets are being ordered, it is essential to see that these are designed to operate in parallel with those already installed. Unless this is clearly stated in the works engineer's specification, the contractors cannot be blamed for offering their standard makes of dynamo, which may or may not be suitable. It is thus not sufficient merely to specify the voltage. Assuming that the tender of a new contractor is more favourable in regard to price, delivery, &c., the engineer will naturally desire to feel free to select this particular make. This he can safely do if he covers the question of parallel running in his specification.

Let us assume that this is not done, and a new dynamo is supplied with a degree of compounding different from one already in use. Suppose the existing machine is under-compounded, the new one over-compounded. What will happen when these machines are coupled in parallel? For the sake of convenience we will call the dynamos "A" and "B." Dynamo "A," being under-compounded, will give a voltage which drops as the load increases. Dynamo "B," on the other hand, will give an increased voltage at the higher loads. "B" will therefore tend to take more than its due proportion of load, causing a still greater discrepancy in voltage; and so on progressively, until all the load is thrown on to this machine. In the end machine "B" may overpower, and send a reverse cur-

rent through the armature of "A," tending to drive it as a motor. Damage may ensue, resulting in serious electrical breakdown.

Even when this risk is guarded against in the specification as indicated above, and the machines are designed for parallel running, there is still a possibility of varying speeds giving rise to varying voltages. This is why engines driving dynamos should be equipped with governors giving very close speed regulation; and this also should be indicated in the specification.

As a further precaution, it is usual to specify that the switchgear shall include "automatic circuit breakers with no-volt and overload release." Any drop in voltage, or any undue increase of load, will then result in the circuit breaker automatically opening the circuit and so preventing damage.

Actual Operation.

Assuming, now, that the various precautions indicated here have been taken, and that the dynamos are designed and equipped with suitable switchgear for parallel running, there remains only the actual procedure for putting the machines into operation together. They are connected electrically through switches to common terminals on the back of the switchboard called "bus-bars," from which feeders supply the external circuits on the gas-works. An "equalizing switch" is also provided, joining the extremities of the fixed windings (at the dynamo brushes) in parallel. The object of this is to ensure that the current to the common external circuit shall flow in the same direction through each series winding with equal magnetizing effect on the two fields. Then, in order to switch-in the second dynamo, it must first be run until its voltage is approximately the same as that of the machine already on load. Then, and not until then, the equalizing switch may be closed, followed by the closing of the switch linking the machine to the bus-bars.

To cut-out any one dynamo, first reduce its speed slightly until it is supplying very little current, open the main switch, and finally the equalizing switch.

An alternative arrangement, involving a little more expense, is to have the switchboard provided with a third, or equalizer, bus-bar. In this case three connections are taken from each dynamo to the switchboard; and the sequence of operations indicated above is taken care of automatically by specially designed triple-pole switches, with a delayed contact for the equalizer pole on each switch.

MANCHESTER AND DISTRICT JUNIOR GAS ASSOCIATION.

Annual Meeting.

The Annual Meeting of the Association was held at the Grand Hotel, Manchester, on April 4—Mr. H. E. Stone (Birkenhead) presiding.

The report was formally approved, after being read by the Hon. Secretary (Mr. J. Alsop). The number of members on the books last year was 217. Since then 18 have been enrolled, 4 have resigned, 10 have ceased to be members by operation of rule 4, 3 have left the district, and there have been 3 deaths; leaving the membership at 215—a decrease of 2.

The Council have elected the Past-President of the Institution of Gas Engineers, Mr. S. Tagg, an Hon. Member of the Association, in recognition of the valuable services he has rendered during his long membership.

The Secretary read a letter from the Institution of Gas Engineers relative to the employment register.

The President presented the prizes for papers read during the session. The awards were given to Mr. W. B. Payne, of Liverpool, and Mr. A. D. Young, of Burnley.

The rule relative to associate membership, passed in 1922, was deleted from the books.

Mr. Stone, the outgoing President, introduced the President-Elect, Mr. J. T. Haynes, of Bolton.

Mr. Haynes moved a vote of thanks to Mr. Stone for his services as President, and presented to him, on behalf of the Council, a certificate on parchment, as a reminder of his presidential year.

Election of Officers for 1925-6.

Junior Vice-President—Mr. W. H. Battersby (Bury).
Hon. Secretary—Mr. J. Alsop (Bolton).
Hon. Treasurer—Mr. I. H. Massey (Oldham).
Auditor—Mr. F. A. Collier (Oldham).
Members of the Council—Messrs. Hailstone (Rochdale), Livesey (Stretford), H. B. Knowles (Lancaster), Young (Burnley), and Prince (Heywood).

After the meeting, the members had dinner together.

The guests of the evening were Messrs. L. Lees (Chairman of the Birkenhead Gas Department), A. L. Holton (Manchester), J. W. Scott (Messrs. R. & J. Dempster, Ltd.), Marsden (National Gas Engine Company, Ltd.), Gillett (President of the Yorkshire Junior Gas Association, and Horwill (Hon. Secretary of the Yorkshire Juniors).

UTILIZATION OF WASTE HEAT FROM COKE OVENS.

[Extracts from a Paper read by Dr. A. Parker at a Meeting of the Coke Oven Managers' Association (Midland Section) on Feb. 28.]

It is assumed that the coal carbonized contains 30 p.ct. of volatile matter, and Table I. gives the average yield of products when this coal is carbonized in waste-heat, recuperative, and regenerative ovens.

Table I.—*Results per Ton of Coal.*

Coke made	14 cwt.
Temperature of coke as discharged	1000° C.
Gas made (debenzolized, saturated at N.T.P.)	11,000 c.ft.
Calorific value, gross	500 B.Th.U. per c.ft.
,, ,, net	440 ,, ,, ,,
Composition by volume—	P.Ct.
CO_2	2·5
C_nH_m	2·0
O_2	0·5
CO	6·0
H_2	53·0

N_2	9·0
	100·0

Type of Oven	Waste Heat.	Recuperative.	Regenerative.
Fuel gas used, c.ft.	9000	7000	5500
Surplus gas available, c.ft.	2000	4000	5500
Temperature of waste gas, ° C.	1100	700	300

Dry Cooling of Coke for Steam Raising—Sulzer Process.

The mean value of the specific heat of coke between 200° and 1000° C. is approximately 0·39. The heat lost by 1 ton of coke in cooling from 1000° to 200° C. is therefore 1,258,000 B.Th.U., which would be sufficient to raise 1296 lbs. of steam from and at 100° C. In practice a certain amount of heat is lost by radiation and convection and in heating-up the circulation gas from ordinary temperature to that at which it finally leaves the boiler. On the other hand, some heat is developed by the combustion of the air with a small fraction of the coke when it first enters the cooler. Tests carried out on the Sulzer plant installed at the Keilehaven Gas-Works and at Schlieren have yielded results which are equivalent to evaporations from and at 100° C. of from 1060 to 1250 lbs. per ton of coke. The proprietors of the process have guaranteed 740 lbs. of steam at 100 lbs. pressure from water at 15° C., which is equivalent to 884 lbs. from and at 100° C. Accepting this figure of 740 lbs., the amount of steam which could be raised at 100 lbs. pressure from 14 cwt. of coke is 518 lbs. Assuming that in the production of electrical energy the consumption of steam per kilowatt hour is 25 lbs. at 100 lbs. pressure, then 518 lbs. would generate 20·7 kw. The fan power required on the Sulzer plant at the Keilehaven Works was 20 kw., and the amount of coke treated was 6 tons per hour, so that in the same proportion a deduction of 2·3 kw. must be made from the 20·7 kw., leaving 18·4 kw. as the net energy available. The net energy which may be recovered by cooling 14 cwt. of coke from 1000° C. to 200° C. may therefore be expressed as 460 lbs. of steam at 100 lbs. pressure, or 18·4 kw.

Steam Raising by Surplus Gas.

With boilers specially designed for firing with gaseous fuel, an efficiency of 80 p.ct. of the net value of the fuel should be attainable in practice.

The net calorific value of the coke-oven gas is 440 B.Th.U. per c.ft. With a thermal efficiency of 80 p.ct. and a consumption of 1000 c.ft., 352,000 B.Th.U. would thus be utilized in raising steam. The amount of steam which could be raised at 100 lbs. pressure from water at 15° C. would therefore be 303 lbs. Calculated on this basis of 303 lbs. of steam per 1000 c.ft. of gas burned under the boiler, the amounts of steam which should be raised from the surplus gas from the carbonization of 1 ton of coal in the different types of ovens, are given in Table II.

Table II.—*Amounts of Steam from Surplus Gas.*

Type of Oven	Waste Heat.	Recuperative.	Regenerative.
Surplus gas from 1 ton of coal, c.ft.	2000	4000	5500
Steam at 100 lbs. from water at 15° C., lbs.	606	1212	1666
Electrical energy in kilowatt hours (basis 25 lbs. of steam)	24·2	48·5	66·6

Surplus Gas and Gas Engines.

The brake thermal efficiency of an ordinary modern gas engine working at three-quarter load is 25 p.ct., and at one-third load 20 p.ct., calculated on the net calorific value of the gas. (*Vide* Clerk, Smithells, Cobb Report to the Institution of

Gas Engineers, 1919.) For the purpose of deducing modest estimates of the power which should be developed by the use of surplus coke-oven gas in gas engines, it is therefore assumed that the thermal efficiency is 20 p.ct. on the net calorific value. The net thermal value of the coke-oven gas considered in Table II. is 440 B.Th.U. per c.ft., so that, of the heat value of 1,000 c.ft., 88,000 B.Th.U. would be converted into power. Since 1 B.H.P.-hour is equivalent to 2545 B.Th.U., 1000 c.ft. of gas would develop 34·6 B.H.P. The power developed by the surplus gas from the three types of coke oven would therefore be as given in Table III.

TABLE III.—*Surplus Gas and Gas Engines*

Type of Oven	Waste Heat.	Recuperative.	Regenerative.
Surplus gas from 1 ton of coal, c.ft.	2000	4000	5500
Power developed by gas engines, B.H.P.	69·2	138 4	190·3
Kilowatt-hour equivalent (90 p.ct. generator efficiency)	46·4	92 9	127·7

EXHAUST-HEATED BOILERS AND GAS-ENGINE PLANT.

It is generally recognized that, even with modern internal combustion engines, approximately 40 p.ct. of the heat of the fuel is carried away through the exhaust pipe. From trials which have been carried out (*vide* I.C.F. Statham, Institution of Mining Engineers, Nov. 19, 1924), it appears that, with properly-designed boilers, about 2 lbs. of steam from and at 100° C. may be raised from the exhaust gases of a gas engine per B.H.P.-hour developed. It is not usually recommended that this method of heat recovery should be employed with engines of less than 100 H.P. Gas engines utilizing surplus gas from coke-ovens would, however, generally be of much larger capacity. Accepting the figure of 2 lbs. of steam from and at 100° C. per B.H.P.-hour, then the amounts of steam which could be raised in this manner from the three types of oven are as shown in Table IV.

TABLE IV.—*Exhaust-Heated Boilers and Gas-Engine Plant. Results per Ton of Coal Carbonized.*

Type of Oven	Waste Heat.	Recuperative.	Regenerative.
Steam at 100 lbs. from water at 15° C. from gas-engine exhaust gases, lbs.	115	231	318
Electrical energy in kilowatt hours	4·6	9·2	12·7

WASTE GASES AND STEAM RAISING.

For the complete combustion of 100 volumes of the fuel gas the composition of which is given in Table I., the theoretical amount of air required is 442 volumes; and the volume of the product gases when reduced to 15·5° C. and 30 in. mercury and saturated with water vapour, would be 400·5 volumes. If it be assumed that the combustion would be so regulated in practice that 541·5 volumes of air would be used, the comparative amount of the waste gases would be 500 volumes at

TABLE V.—*Waste Gases and Steam Raising.*

Type of Oven	Waste Heat.	Recuperative.	Regenerative.
(1) Fuel gas used, c.ft.	9,000	7,000	5,500
(2) Volume of waste gas leaving installation (reduced to 15·5° C., 30 in. saturated), c.ft.	45,000	35,000	27,500
(3) Weight of water vapour accompanying waste gas, lbs.	504	392	308
(4) Temperature of waste gas leaving installation, °C.	1,100	700	300
(5) * Sensible heat of waste gas and water vapour, therms	27·64	14·96	6·85
(6) * Heat value of waste gas entering boiler, therms	25·43	14·21	6·71
(7) Volume of waste gas entering boiler (reduced to 15·5° C. and 30 in. saturated), c.ft.	58,500	45,500	35,750
(8) Composition of waste gas at inlet of boiler: Volumes p.ct. CO_2	6·4	6·4	6·4
O_2	8·0	8·0	8·0
N_2	85·6	85·6	85·6
	100 0	100·0	100·0
(9) Temperature of gases at inlet of boiler, °C	821	534	236
(10) Temperature of gases at outlet of boiler, °C.	250	250	..
(11) * Heat value of gases at outlet of boiler, therms	11·34	8·82	..
(12) Heat available for raising steam, therms (gross)	14·09	5·39	..
(13) Heat available for raising net steam, due allowance being made for fan power, &c., therms	13·10	5·01	..
(14) Net steam at 100 lbs., from water at 15° C., lbs.	1,129	432	..
(15) Electrical energy in kilowatt hours (25 lbs. of steam per kilowatt hour)	45·2	17·3	..

* The heat values include the latent heat of water.

the points at which the products leave the battery of ovens. The composition of the waste gas would then be represented by 8·3 p.ct. of CO_2 and 4·2 p.ct. of oxygen; in addition, the water vapour carried by the fuel gas and air, and resulting from the combustion of the fuel gas, must be taken into account.

Combining the data given in the first four items of Table V. with the specific heat values given in Partington and Schilling's "Specific Heats of Gases," and calculating from a base line of zero Centigrade, the heat values in item (5) of Table V. are obtained. In practice it is found that during the passage of waste gases from settings of retorts or ovens to waste-heat boilers, large volumes of air leak into the flues, with the result that there is a considerable lowering of temperature. For the purpose of these calculations, it has been assumed that the amount of air infiltration is 150 volumes for every 500 volumes of waste gas. A certain proportion of heat is also lost by radiation and convection from the flues leading from the installation to the boiler. These heat losses have been assumed to be 8 p.ct., 5 p.ct., and 2 p.ct. of the heat values of the waste gases respectively for the three types of oven. These assumptions are necessarily approximate, since the actual losses vary with different installations. After making the necessary allowances for air infiltration and heat losses from the flues, the figures given in items (6), (7), (8), and (9) are obtained.

SUMMARY.

Waste Heat from Coke Ovens.

Type of Oven	Waste Heat.	Recuperative.	Regenerative.
Total energy in kilowatt hours per ton of coal (all waste heat used for raising steam)	87·8	84·2	85·0
Total energy in kilowatt hours per ton of coal (surplus gas used in gas engines—the exhaust gases being passed through a waste-heat boiler—other waste heat used for steam raising)	114 6	137·8	158·8

Whether waste-heat recovery should be practised by all or any of the methods considered, states Dr. Parker, is a question the answer to which must depend on how far the energy developed can be profitably used.

BRITISH ASSOCIATION OF CHEMISTS.

On Friday, April 3, Dr. E. F. ARMSTRONG, the President of the British Association of Chemists, addressed a meeting of the Birmingham Section of that body at the Queen's Hotel. Members were present from the Society of Chemical Industry, the Institute of Chemistry, and the Chemical Society.

Dr. Armstrong spoke on "The Profession of Chemistry; What Can we Make of it?" There was need, he said, in this democratic age, that chemists should take stock of their position; and he believed, when this was done, it would be realized that an organization fuller, and with a broader scope, than anything now existing would be necessary to provide for the various grades of men who might fairly claim to represent the profession of chemistry. He was strongly of opinion that there was no need for the present multiplicity of societies and organizations, each of which was supposed to represent some particular interest. In view of the fact that there were a number of societies in the chemistry profession, he would like to preach the philosophy of the "middle-way" among chemists. One of their troubles was that no one understood them. They could never be what they thought they were unless someone really admired them. Their mission should be to make the nation understand what chemistry was; what it had done; and what it was doing. There was need for new propaganda methods.

Some of them had done their best to bring together societies catering for the interests of various sections of chemists; but such a movement would only succeed when it came from the mass of the members. If it came from the bottom upwards, and there was insistence that the societies should combine, then chemistry would achieve something. What was wanted was a register of chemists, and a central home for chemists in London to start with, and later on, if they could get them, homes in provincial centres. A third ideal was that they ought to have one journal. Everybody who reached a certain attainment in chemistry ought to be registered as a chemist; and this attainment could be measured in a number of ways. He did not see any difficulty in setting-up such a register; and then they would have one body qualified to speak for all chemists. The management would probably present difficulties. One scheme might be that each class would have its own council or committee, and be represented on a basis proportional to the number of the members on a central council. Such a body would be a proper one to watch over the benevolent side of the chemical profession, as well as over professional interests.

If all chemists were one big body like this, one of the duties

would be to promote the cause of chemistry. It would have its scientific group for promoting pure research, as now represented by the Chemical Society. It would have its industrial group, holding meetings for the reading and discussion of papers on applied chemistry. Thus they would be doing work now undertaken by the Society of Chemical Industry. Finally, there could be a third group, interested in the application of engineering to chemistry—a function which was partly filled by the so-called Engineering Group, and the so-called Group of Chemical Engineers. Thus would these become groups of one body, which should be in a position to speak for all chemists on all occasions.

FURNACE DESIGN AND PERFORMANCE.

[Extracts from a Paper by T. R. Speck, of the B.S.A. Company.]

It is interesting to have the views of an actual user of gas furnaces. These are expressed in a paper read before the Birmingham Association of Mechanical Engineers by Mr. T. R. Speck, of the Birmingham Small Arms Company. After stating that gas-fired furnaces are deservedly the most popular in the Birmingham district, the author goes on to consider

Thermal Efficiency.

The thermal efficiency of a furnace may be represented as follows:

Total heat content in B.Th.U. in material leaving furnace, *minus* initial heat content in B.Th.U. on entering furnace, multiplied by 100, and divided by the gross B.Th.U. content of the fuel consumed during the heating of the material.

Let W = weight of metal in lbs.
T_1 = initial temperature of metal, ° Fahr.
T_2 = final ,, ,, ,, ° Fahr.
S = specific heat ,, ,,

$$\text{Then } \frac{(W \times S \times T_2) - (W \times S \times T_1)\ 100}{\text{Total B.Th.U. value of fuel used}} = \text{thermal efficiency.}$$

The specific heat of metals varies at different temperatures, and for mild steel from zero to melting-point is about 0·160 to 0·165. This figure, though not strictly correct, will give reasonable accuracy for ordinary annealing and hardening temperatures. There does not appear to be any information available as to the effect of the introduction of nickel, chromium, &c., on the specific heat of steels.

The lower curve B on fig. 1 shows the B.Th.U. content in 1 lb. of 0·30 carbon steel at various temperatures. The correct specific heat figures for the different temperatures (as given by Meuthen) have been used. The straight line indicates the amount of error produced by using the mean figure of 0·160. The upper curve gives the thermal efficiency of a furnace fired by gas of a calorific value of 480 B.Th.U. gross, when 1 lb. of steel is raised by 1 c.ft. of gas to the various temperatures shown. The initial temperature of the steel has been assumed as 62° Fahr. in all cases. To find the efficiency when different quantities of gas are used per lb. of steel heated, divide the percentage efficiency shown by curve A by the number of cubic feet used. The above curves will be found very useful in going into the question of furnace economy. Thermal efficiency is one of the readiest means of comparing the performance of different furnaces. There are, of course, other factors that count, such as even temperature distribution, &c.

Need for Standardized Tests.

When selecting a furnace for a particular job, it is difficult to find out exactly what the fuel consumption is going to be under stated conditions. Some makers base their estimates on gas consumed per pound of metal heated; others appear per the superficial area of the furnace chamber—a figure which may vary from 10 to 15 c.ft. of gas per sq. ft. at temperatures from 800° to 900° C. The latter method may be reasonably correct for some furnace loads, but varies considerably with different weights and nature of load. It would be of great assistance to the furnace buyer if some standardized form of test could be adopted for each class of furnace. He would then be able to satisfy himself as to the relative merits of various machines offered, and price would only affect the issue in so far as value for money was concerned. A recognized test of this description could also be a guide to the engineer, helping him to decide on the economic life of the furnace linings, &c. In any form of standardized test, thermal efficiency should be given a prominent place, as also should the fuel consumption required to maintain a definite temperature with the furnace empty.

The chief use of the thermal efficiency figure is for purposes of comparison. If the machines are required for general purpose work, it will be a good guide as to which furnace is likely to prove most economical—always assuming that the size and the general design are suitable for the work. There are many reasons why the true thermal efficiency cannot often be obtained in practice—for example, scale or grease on the work may affect the rate of absorption; and work in pots can be heated much quicker if suitably distributed throughout the furnace than if packed together in a heap. It will be readily realized that a hundredweight of steel in billet form will absorb the same number of B.Th.U. on being heated from (say) 600° to 900° as will a hundredweight of thin coil springs; but as the latter offer far more surface area for the absorption of heat, it follows that, with the furnace at the same temperature, they reach the temperature required in much less time than the billet, while the radiation, flue, and other losses, which in most furnaces represent over 60 p.ct. of the heat generated, are more in proportion to the time taken for the operation. Carburizing work in pots shows up even worse than the billets; for, not only is the work well insulated by the carburizing material in the pots, but, after it has reached the proper tem-

perature, a long period is required to obtain the necessary depth of carbon penetration.

There is scope for development in the control of combustion and furnace atmosphere.

FURNACE ECONOMY.

Furnace economy cannot be obtained unless proper attention is given to the matter of insulation. The 4½ in. or so of firebrick sometimes met with is by no means adequate. The makers of this class of furnace must, of course, be aware of this fact, so one can only presume that price is often the factor which most influences the purchaser, and that insufficient attention is given to the efficiency and other merits of the furnace. Good results can be obtained in furnaces required for temperatures of about 900° C. if the usual firebrick lining is enclosed by 4½ in. of insulating brick (of the Nonpareil or Moler type). This may with advantage be further backed by magnesium slabs or asbestos board. When this practice is followed, care should be taken to see that the furnace arch is well supported, otherwise the lateral thrust may compress the magnesium slabs, with consequent fracture of the arch.

Fig. 2 clearly shows the value of proper furnace wall thickness and construction.

Fig. 3 shows the heat losses by radiation, conduction, and convection from a vertical surface—*e.g.*, the sides of a furnace. The losses through the furnace top due to convection are more than for the sides, and the losses through the bottom are less.

RECUPERATION AND REGENERATION.

Hot flue gases are responsible for serious loss of furnace efficiency. This loss can be reduced to a minimum by transfer of the heat contained by the outgoing flue gas to the incoming air required for combustion. This transfer not only returns sensible heat to the furnace which otherwise would be wasted, but also reduces the specific gravity of the air, which enables it to mix more thoroughly and quickly with the gas. The speed of mixing is important, as it has considerable influence on the speed of combustion, which, of course, affects flame temperature. High flame temperatures are important, as the rate of heat transfer from the hot gases to the work and the furnace is governed by the difference in temperature between the gas and the work.

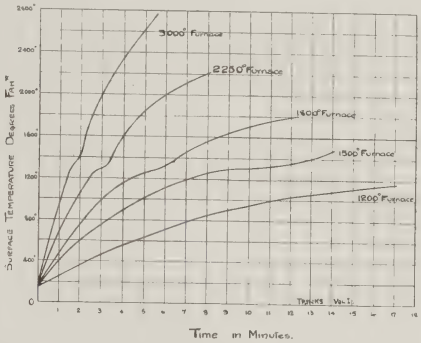

Fig. 4.—Time required to heat Bars, at Varying Furnace Temperatures.

Fig. 4 illustrates this point. It shows the relative time taken to heat up a 1-in. diameter bar at different furnace temperatures.

Percentage Heat of Combustion in Flue Gases
Percentage Heat of Combustion in Flue Gases
Davis Furnace Co.
Temperature of Gases in ° C.

Fig. 5.—Heat Losses by Flue Gas at Various Temperatures.

Fig. 5 is drawn from information published by the Davis Furnace Company, and shows the percentage of heat of combustion contained in flue gases at various temperatures. If we take an air-blast gas furnace with gases leaving the flue at 1250° C., we see that 60 p.ct. of the heat generated is lost, whereas, if the flue gas temperature is by efficient recuperation reduced to 200° C., the loss is only 7 p.ct.

Fig. 6, compiled from the same source, shows the recuperative value of air when the total amount required for combustion is heated by the flue gases to various temperatures.

Figs. 5 and 6 indicate theoretical conditions; but there is no reason why they should not be approached in practice. The very low flue-gas temperatures cannot, however, be absolutely attained, partly owing to the loss of the latent heat of the moisture contents of the flue gas which finally leaves the furnace in an uncondensed state.

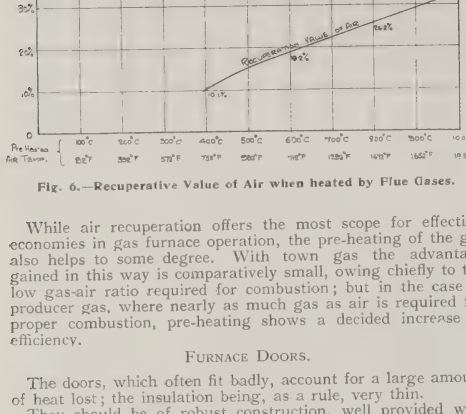

Fig. 6.—Recuperative Value of Air when heated by Flue Gases.

While air recuperation offers the most scope for effecting economies in gas furnace operation, the pre-heating of the gas also helps to some degree. With town gas the advantage gained in this way is comparatively small, owing chiefly to the low gas-air ratio required for combustion; but in the case of producer gas, where nearly as much gas as air is required for proper combustion, pre-heating shows a decided increase in efficiency.

Furnace Doors.

The doors, which often fit badly, account for a large amount of heat lost; the insulation being, as a rule, very thin.

They should be of robust construction, well provided with insulation, and large enough to cover fully the furnace opening and make a virtually gas-tight joint with the furnace front when shut and clamped-up. The weight and bulk of a substantial door are no detriment if a balanced quadrant and operating lever be provided, instead of the more usual chain and weight, which, even with a light door, is anything but "handy."

A New Annealing Furnace.

With the object of reducing the cost of pot replacements and also the cost of fuel used per unit of work produced, and at the same time of increasing the output, a new type of continuous bright annealing furnace has recently been put on the market. I have had an opportunity of testing and observing the performance of one of these furnaces (made by the Lucas Furnace Company) for the last fourteen months or so. It was designed for close annealing bright steel pressings for the motor and cycle trades, and was put in competition with two other gas-fired furnaces of high efficiency and repute. In both cases full advantage was taken of air recuperation and proper insulation. After one or two modifications to the furnace, the claims made have been fully justified. Clean bright work can be produced, thick heavy pots have been eliminated, the labour cost has not been increased, the output per furnace has been in most cases doubled or trebled, and the gas consumption per pound of metal treated has been reduced by 50 p.ct., and in some cases by 66 p.ct. Further experiments are being made, which, I am convinced, will have the effect of reducing the gas consumption still more. The time elapsing between the components leaving and returning to the press shop has been reduced by over 50 p.ct., which will enable a larger output to be obtained with less floating stock; the machine is easily managed by semi-skilled labour; and the quality of output is satisfactory. Rusty work can be put into the furnace and brought out practically clean without extra cost.

Running Costs of Furnaces.

I propose to give a few figures as to the comparative costs of running a few furnaces of different makes and types under actual manufacturing conditions; the object of this being to impress on the engineer some of the advantages he may expect to gain by giving the same close attention to the selection and running of his furnaces as he does to his machine tools. In the following tests all the furnaces are by makers of wide repute, and were supplied for the class of work upon which the tests were conducted. The majority of the furnaces are run continuously day and night during the working week, and the tests were all of several hours' duration. It is not claimed that the results are particularly good. The tests were carried out in order to compare the various makes and types of furnaces under normal working conditions. The furnaces grouped together for comparison are similar in size, and the work done is the same. Other conditions were as nearly as possible the same.

Table I. gives the comparative gas consumption of various furnaces used for re-heating work after carburizing.

Table I.—*Reheating after Carburizing.*

Furnace.	C.Ft. of Gas per Lb. of Metal Heated.
1. American forced-draught, under-fired	5·92
2. British fan draught, recuperative	2·56
3. British natural draught, regenerative	2·44

Table II. gives the gas consumption of various furnaces on carburizing.

Table II.

Furnace.	C.Ft. of Gas per Lb. of Net Useful Load Heated.
1. Reverberatory, natural draught	56
2. Forced draught, under-fired with flat roof	88·5
3. Forced draught, under-fired with arched roof. Roof slightly lower than No. 2	53·5
3a. As No. 3, but with better insulation	42
3b. As No. 3a, with air heated to 175° C. by flue gases	35·7*
4. Regenerative	29·5†

Gas per lb. gross load, 15 p.ct. of above.

* Saving of 33⅓ p.ct. over No. 3.

† Slightly larger furnace than the above, holding larger load.

Note.—Weight of carbonizing boxes and material not included as useful load.

Table III. gives the costs of running the bright annealing furnace and the ordinary type of close annealing furnace.

Table III.—*Comparative Running Costs of the Bright Annealing Furnace and Modern Recuperative or Regenerative Furnaces under Working Conditions.*

Conditions: Full load over extended periods on various classes of steel pressings requiring to be close-annealed without scale.

Work.	Standard Types of Furnace (Regenerative or Recuperative).		Bright Annealing Continuous Furnace.	
	No. per Hour Output.	Gas Consumed per Lb. of Metal.	Output per Hour.	Gas Consumed per Lb. of Metal.
		C.Ft.		C.Ft.
A. Light bulky components	210	14·9	480	4·26
B. Lightsmaller components	108	10·1	200	3·49
C. Medium small components	72	11·2	120	4·26
D. Heavy larger components	25	8·13	36	3·6
	Average =	11·1 c.ft. per lb. of metal annealed	Average =	3·73 c.ft. per lb. of metal annealed
Hourly running cost, including pot wastage and miscellaneous stores	23d. for 67·6 lbs. of metal 0·34d. per lb.		16·36d. for 129 lbs. of metal 0·126d. per lb.	

[Since the above tests, this has been reduced, but it is early yet to say how far the reductions will be permanent.]

The labour costs were the same in both cases; but if two bright annealing furnaces had been available, the labour cost on same would have been reduced by 50 p.ct. Also, there is no doubt that the thermal efficiency of the bright annealing furnace can be improved by better insulation and better means of ensuring complete combustion of the gas. The gas used per lb. of metal annealed is for the net amount of useful work produced; the weight of the pots is not included as useful load.

"Vertical Retorts."—At the next meeting of the Junior Institution of Engineers, to be held at No. 39, Victoria Street, S.W., on Friday (April 17), a paper on "Vertical Retorts," illustrated by lantern slides and models, is to be read by Mr. Walter T. Dunn, M.I.Mech.E.

Iron and Steel Institute.—The annual meeting of the Institute is to be held at the Institution of Civil Engineers, Great George Street, S.W., on Thursday and Friday, May 7 and 8. Sir Frederick Mills, Bart., will deliver his Presidential Address, and a number of papers will be presented. Members will dine together at the Hotel Cecil on the Thursday evening.

Seventy-Five per Cent. Waste.—In the speech of Mr. H. James Yates at the annual meeting of Radiation Ltd., as reported in the "Journal" for April 1, there was a printer's error in the paragraph headed "The Smoke Problem." Mr. Yates was made to say: "When coal is burned in its crude form in an ordinary coal grate, the direct waste of fuel is estimated at 5 p.ct." It will have been obvious to most of our readers that the "5" should have been "75."

THE GAS INDUSTRY IN NEW ZEALAND.

[A few extracts from the Presidential Address delivered by Mr. James Lowe, M.Inst.C.E., Manager and Engineer of the Auckland Gas Company, Ltd., at the First Annual Meeting of the Gas Institute of New Zealand.]

The density of population in our cities and towns is much less than in the Homeland. This arises from the practice of building—except in principal streets—houses of the detached type on sections usually not less in size than a quarter of an acre. This practice, while it has many advantages, is the cause of a greater expenditure on mains than might otherwise be necessary. The incidence of the cooking load also is different from that in Britain. The chief meal of the day for all classes of people is taken in the evening; and in winter the peaks of the lighting, heating, and cooking loads overlap between five and six o'clock. In fact, the incidence and nature of the cooking load as compared with lighting tends to increase the capital expenditure, per 1000 c.ft. of gas sold, on mains. However, by means of high-pressure distribution superimposed on a low-pressure reticulation system, great economies can be made in the cost of mains in a growing district.

Gas Engineers Their Own Contractors.

Gas engineers and managers in the Dominions have to rely on themselves to a much greater extent than their confrères at home have to do. There are practically no firms within easy reach who specialize in the manufacture of gas plant available. In consequence, the engineer has not only to prepare plans, specifications, and detailed estimates of much of his plant, but in addition has frequently to do the fabrication and almost invariably the erection with his own staff. For this reason the larger gas-works in the Dominions are equipped with workshops and appliances on a scale exceeding that to be found in similar-sized works in Britain, where there is a much greater dependence on contractors for repairs, as well as for new work. One result of the war has been to encourage the manufacture of plant in the Dominion.

It takes at least five months—often much longer—to receive goods from Britain after ordering by mail; and it is necessary for New Zealand gas engineers and managers to look well ahead with their requirements. They must devote some little attention to the matter of indenting, for it is a serious matter to run short of essential things, the absence of which would seriously interfere with the manufacture or supply of gas.

Effects of Freight Insurance Tariff.

The facts that we are from twelve to thirteen thousand miles away from the manufacturers, and that New Zealand possesses a Customs Tariff, add considerably to the cost of our imports. The costs of freight, insurance duty, wharfage, &c., have to be added to the home cost, so that on the average we have to pay from 40 to 50 p.ct. more than our confrères in Britain for all goods we import. Rates of wages also are higher in the Dominion than they are in Britain. These conditions, together with the greater cost of coal, explain why gas prices must be higher in the Dominion than they are in Britain.

Unfair Competition.

The gas industry has to face competition from power boards supplied with electricity from State hydro-electric works. The Government are spending huge sums on these schemes, and are subsidizing them in various ways. The power boards are required to pay neither income-tax nor local rates, and deficits are made good from the general revenue of the State. In addition, they receive indirect subsidies through the Customs, since "all machinery and appliances peculiar to the generation of electricity," including electric motors, cables, insulators, &c., are duty-free, while gas and steam engines are charged 10 p.ct duty, and cast-iron pipes above 9 in. diameter and steel pipes above 6 in. diameter 20 p.ct. duty. It is only fair to say, however, that machinery for any manufacturing purposes is now admitted free of duty provided it can be shown to the satisfaction of the Minister of Customs that the same could not have been economically manufactured in New Zealand.

Labour Legislation.

Perhaps the most uncongenial duties which fall to the lot of gas-works engineers and managers in New Zealand are those in connection with industrial disputes. The Industrial Conciliation and Arbitration Act of 1908 and the Labour Disputes Investigation Act of 1913 are probably the most advanced labour legislation in the world. Under these Acts the maximum term for which awards and agreements can be made is three years, but in practice the award or agreement is almost invariably fixed for a term of two years. Disputes are therefore automatically created in every trade or class of labour every two years. The workers' Unions are nearly always the applicant parties, and they draw up and serve on employers schedules of demands which are not usually characterized by moderation. Shorter hours, higher wages, increased rates for overtime, extra pay for certain classes of work, &c., are usually demanded.

Employers have then to draw up counter proposals, and to spend much time in Conciliation Council or at the meetings of a Labour Disputes Committee. These meetings sometimes continue for a fortnight; and when no settlement is reached, the dispute goes to the Arbitration Court if under the Industrial Conciliation and Arbitration Act, or to a vote of the workers as to whether they will strike or not, if under the Labour Disputes Investigation Act.

Gas engineers and managers in New Zealand have to devote to labour matters much more time than have their confrères in Britain.

Coal.

The only bituminous coals in the North Island are found in the neighbourhood of Whangarei, about one hundred miles north of Auckland, but these coals are not used for gas manufacture, on account of their high content of sulphur, which is about 4 to 5 p.ct. The chief coalfield in the North Island lies about 100 miles south of Auckland in the valley of the Waikato, and is an excellent lignite. Unfortunately its yield per ton is only about 10,000 c.ft. of gas having a calorific value of 400 B.Th.U., or 40 therms. The coke is exceedingly friable, light, and difficult to quench. Needless to say, this lignite coal is not much used for gas manufacture. In Auckland we—in common with the other New Zealand gas-works—draw our principal coal supplies from the Maitland coalfield of New South Wales and from the West Coast mines of the South Island of New Zealand.

A comparison of prices of coal delivered into the Auckland Gas-Works in 1913 and 1924, together with the prices charged for gas, is of interest:

Year.	Coal.		Gas.		Income-Tax.	
	Cost per Ton.	P.Ct. Increase.	Price per 1000 C.Ft.	P.Ct. Increase	Rate per £1.	Pence per 1000 C.Ft.
	s. d.		s. d.		s. d.	
1913 ..	22 4	..	4 3	..	1 2	0·68
1924 ..	42 9	93	7 6	76	5 10	6·02

The Auckland Gas Company, Ltd

The memorandum of the Association of the Company is dated July 23, 1862. On April 15, 1865, gas was supplied for the first time. The output in 1866 was 6,755,000 c.ft. and the price 20s. per 1000 c.ft. In 1924 the output was over 1302 million c.ft. Altogether there are 403 miles of low-pressure reticulation and 48¾ miles of high-pressure mains ranging in size from 18 in. to 3 in. For low pressure, ordinary cast-iron mains with cast lead joints are used, for high pressure, wrapped and coated steel tubes with long rigid joints are preferred. The manufacture of firebricks and retorts as a branch of the Company's business was begun in 1884.

Warner Low-Temperature Retort.

The Economic Carbonization Company are completing at Petersburg (Va.) an installation of four retorts of commercial size designed and patented by Mr. A. W. Warner, which, it is stated by Dr. Horace C. Porter, in a paper submitted to the Franklin Institute, on "Low-Temperature Coal Carbonization and Its Prospective Industrial Development," will utilize the principle of withdrawal of the volatile matter chiefly in a direction away from the source of heat. The retorts are vertical, made of metal (of special heat-resisting alloy in the top section), and heated in a setting of gas-burning flues. These flues provide higher heat at the top of the retorts, and lower at the bottom. Within each retort is a worm conveyor propelling the coal upward; and through the hollow shaft of this worm the gases are drawn-off. The feed of coal is so designed that it meets the off-coming gases and vapours, cooling them and seturning the condensed heavy oils with the coal into the retort. It is claimed by the inventor that the condensates, since they bear no free carbon or pitchy residues, will not clog the outlets. The minimum capacity of this retort is set down at 10 tons per day. The process is designed to produce a free-burning coke of not over 2 p.ct. volatile matter, a high yield of oils, a fair yield of ammonia, and about 8000 c.ft. of 750 to 800 B.Th.U. gas. The Petersburg plant is expected to operate commercially in conjunction with the local gas-works, and turn its gas into the city mains. It is a process wherein low-temperature carbonization is combined in an ingenious manner with certain features of high-temperature carbonization; and, he adds, its practical development is to be awaited with special interest.

Yorkshire Junior Gas Association.—Arrangements have been made for members to visit, on Saturday afternoon, April 18, the works of Messrs. J. Blakeborough & Sons, Ltd., in Birds Royd Road, Brighouse. Visitors will assemble at the works at 3 o'clock.

London and Southern District Junior Gas Association.—A meeting will be held at the Westminster Technical Institute, Vincent Square, S.W. 1, on Friday next, April 17, at seven o'clock, when Mr. Dean Chandler, of the South Metropolitan Gas Company, will read a paper entitled "Fuel in Industry."

CORRESPONDENCE.

[We are not responsible for opinions expressed by Correspondents.]

Spirally-Guided Flying Lifts.

Sir,—With reference to the two letters appearing in your last issues as to the patent of our Mr. William Blakeley, we would like to make it clear that, at the time of taking out this patent, we were not aware that any similar idea had been previously adopted.

In view of the evidence now put forward, we realize that, though the patent has been granted to us, we cannot object to those firms who, prior to the patent, had added spiral flying lifts of their own design to column-guided gasholders.

The system of spirally-guided flying lifts as designed by us and on our principle is, we submit, substantially stronger and safer than the ordinary method of flying-lift construction, and gives the same stability to the flying-lift as in the usual lifts of the ordinary spiral-guided gasholder.

Last year we constructed a new three-lift gasholder on this principle on the South Coast, which has proved very satisfactory, having stood without "flinching" the exceptional gales experienced at the end of last year, though fully inflated the whole time. Those who were residing on either the Kent or Sussex coast at that time will know what a severe test to a gasholder that occasion was.

Our firm have another gasholder in hand for a Southern works on the same principle. We contend that no independent engineer who thoughtfully studies our design can deny it is a far safer proposition than the ordinary type of flying lift.

For Firth Blakeley, Sons & Co., Ltd.,
H. Blakeley,
Secretary.

Church Fenton, via Leeds,
April 10, 1925.

REGISTER OF PATENTS.

Carbonization.—No. 228,763.

Rude, J., of Hyde Park, W. 2.

No. 12,681; May 23, 1924.

This invention is a development of that contained in specification No. 204,718. The latter relates to carbonization of solid fuel consecutively in an internally-heated low-temperature retort and an externally-heated high-temperature retort; the process consisting mainly in the utilization for carbonization purposes of the heat of the flue gases, which have served to heat the high-temperature retort externally, by leading them to a heat interchanger, where the gaseous fluid which, by its sensible heat, performs the low-temperature operation in the internally-heated retort, is heated.

In the original application, the gaseous fluid which performs the low-temperature operation, and the gases emanating from the externally-heated retort, meet and mix outside the retorts. According to the present invention, the two retorts are now arranged in such a way that their interiors communicate freely, and virtually constitute one apparatus comprising an upper and a lower retort, so that the fuel within them forms an unbroken column, the lower part of which is subject to external heating, and the upper part to internal. This communication of the retorts makes it necessary that the gases produced in the externally-heated part shall not be removed from the latter for the purpose of mixing them with the gaseous fluid destined for the low-temperature operation in the internally-heated part, but shall on the contrary be left to ascend freely through both retorts, so that the encounter of the gases from the lower retort and the gaseous heating fluid takes place somewhere in the interior of either of the two retorts.

The reason for the suggested modification is to make it possible to carbonize a fuel in lump form—for instance, coal briquettes, which, to avoid breakage, can pass consecutively through both retorts without meeting any obstructions on the way, which are inevitable if the gases from the lower retort are prevented from entering directly into the upper retort.

Another feature of the new invention relates to leading the gaseous fluid, which performs the carbonization in the upper retort by its sensible heat, through the hot coke in the lower part of the externally-heated retort, before the fluid enters the heat interchanger. The reason for this innovation is twofold. First, the contact of the gaseous fluid with the hot coke causes a conversion of the hydrocarbon vapours into permanent gases, and thus prevents a decomposition of the hydrocarbons from taking place later on in the heat interchanger, where cracking may interfere with its regular working. Secondly, the sensible heat of the coke is to a large extent transferred to the gaseous heating fluid and subsequently utilized for carbonization, the coke being at the same time cooled.

Dry Meters.—No. 228,795.

Cooke, A. G., and Phillips, B. C., both of Joymanco (Brighton) Limited, of Hove.

No. 19,304; Aug. 14, 1924.

(Patent of Addition to No. 207,072, Jan. 5, 1923.)

The parent patent was noticed in the "Journal" for Dec. 26, 1923. The measuring chamber is now modified by the rim having an annular recess stamped or swaged to the outer edge, being of a shape approximating to the form of a half-ellipse. A split ring is inserted over the removable diaphragm and mounted in the annular recess compressing the flexible material of the removable diaphragm at two separate positions, each being near the respective end of the swage in the rim and allowing the dressing oil in the flexible material to be retained between the compressed portions. An annular V or U shaped groove is formed in each of the discs of the diaphragm.

Ascension Pipes.—No. 229,863.

Mackenzie, M., of Ecclesfield, Sylvester, J., of Barnsley and Outwin, E., of Worsborough.

No. 5272; Feb. 29, 1924.

According to this invention, an ascension pipe comprises sections each provided with a plurality of openings at intervals in its length, adapted to be temporarily sealed. Conveniently these openings are provided with removable plugs, flap doors, or equivalent means whereby they may be temporarily closed; but if desired, they may be stopped with fireclay, &c. Preferably the openings are formed in bosses cast on the pipes, the axes of the openings being at an angle with the axis of the pipe.

The openings may be at uniform intervals along the pipe or closer together adjacent to the foot than elsewhere, where also they may be larger than the openings remote therefrom. Usually it will be found preferable to arrange adjacent openings in staggered relationship one with the other.

Normally, air will be admitted to the pipes through the openings for the purpose of burning out the deposit when the oven is taken off from the gas main and is awaiting discharge, the order of unsealing of the openings being preferably from the top toward the foot. The admission of air through several openings facilitates burning out the carbon; and the removal of the deposit may be further facilitated or accelerated by rodding.

Producers.—No. 229,891.

Regenerative Coal Gasification System, Ltd., Travers, M. W., both of Queen Victoria Street, E.C. 4, and Clark, W., of Lymm.

No. 8653; April 5, 1924.

This invention relates to gas-making plant as described in specifications Nos. 198,777 and 210,356 [see "Journal," Vol. 163, p. 312, and Vol. 165, p. 569, respectively].

According to the present invention, the patentees divide the carbonization chamber of the plant into compartments by means of vertical or substantially vertical partitions extending for part or for the whole of the distance from the top of the carbonization chamber to the nostril leading to the regenerator, so that the mass of coal is sub-divided. They find, especially in the case of large plants, that by such subdivision a better yield is obtained, as the coal undergoes a more uniform and more rapid treatment than is possible when there is a large undivided mass.

Testing Pipe Joints.—No. 229,991.

Ross, D., and Weiser, R. F., both of Newport, and The British Mannesmann Tube Co., Ltd., of Queen Victoria Street, E.C. 4.

No. 1316; Dec. 21, 1923.

This invention relates to pipe-testing apparatus of the type mentioned on p. 127 of last week's "Journal" as having been patented by the same claimants.

According to the present invention, the casing, which consists of a segmental split ring and a segmental closing member disposed in a gap arranged between the ends of the ring, is expanded by the instrumentality of a bolt which is connected at one end to a lug on the closing member and at the other end is adjustably housed in a socket formed in a lug on the ring, in conjunction with toggle mechanism comprising a collar slidably mounted on the bolt, toggle links pivotally connected with the collar and bearing against projections provided on the terminal portions of the ring, and means for moving the collar along the bolt.

Furnaces.—No. 230,125.

Gibbons Bros., Ltd., and Marle, M. V., both of Dudley, and Walter, C. M., of Birmingham.

No. 24,804; Oct. 5, 1923.

This invention relates to gas-fired furnaces in which chambers for preheating air and gas are located within the walls of an enclosed furnace and below the working chamber or chambers thereof; the preheating chambers being heated by the exhaust gases of the furnace. The object of the invention is to provide a more efficient and more easily controlled and regulated furnace.

According to this invention, the furnace comprises separate air and gas regenerative chambers adapted to be heated by contiguous chambers through which the exhaust gases pass, separate conduits leading to the burners, valves for controlling the air and gas between the chambers and the burners, gas ports in the burners, and separate air ports disposed laterally of the gas ports. The arrangement is such that the air issuing from the ports converges towards and mixes with the gas stream, prior to which the air has been maintained entirely separate from the gas.

In one construction a plurality of separate burners located longitudinally below the working chamber have each a central section delivering gas and two separate outer sections delivering air. The air preheating passages are arranged in two groups between three groups of exhaust passages, and one of the air sections of each burner is connected by a separate passage with one of the preheating groups, while the other air section of each burner is similarly connected with the other group of preheating passages.

In an alternative construction the air passes from a plurality of groups of air preheating passages into a common chamber, and conduits convey the air from the common chamber to a plurality of points near each side of the working chamber.

These forms of the furnace are fully described in the specification, in connection with 13 detail drawings.

Gas Taps.—No. 230,143.

Helps, G., of Nuneaton.

No. 30,048; Nov. 29, 1923.

The patentee says that "the main object of this invention, as indeed has before been proposed, is to utilize the pressure available

while a burner is called on to pass small quantities of gas, so that the flame may be produced always from a completely combustible mixture. The burner can be used in districts having different qualities and pressures of gas without alteration except bringing a different number of nipples into action."

The plug on the barrel of the gas cock claimed contains a plurality of gas ways acting as nipples or provided with nipples injecting gas into a single burner; the arrangement being such that as the cock is opened or closed, one or more or all of the gas ways is or are brought into operation.

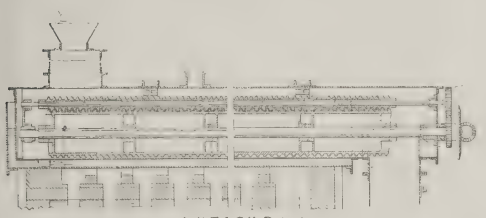
Heat Treatment for Distilling, Drying, or Carbonizing.

No. 230,223.

"T.I.C." Research Co., Ltd., Duckham, Sir A. M'D., Rider, D., and Watts, J. S., all of Grosvenor Gardens, S.W. 1.

No. 1413; Jan. 17, 1924.

By this invention, which relates the heat treatment of materials for distilling, drying, or carbonizing them in a trough, retort, or the like heated by molten metal, it is claimed that the material is distributed in a comparatively thin layer over the heating surface by a device which both spreads the material as a layer and turns it over, and that in this manner practically every particle comes into contact with the heating surface during the process.



A "T.I.C." Retort.

It is pointed out that the invention is particularly applicable for the known method of subjecting coal which is to be coked to a preliminary low-temperature carbonization; also for the destructive distillation of shale, and for the distillation of tar oil until a coke residue is obtained.

We reproduce part of a longitudinal sectional drawing which accompanies the specification, omitting the oil-fired furnace and extractor shown in the original. A trough-shaped retort is set in a correspondingly shaped bath containing lead which is kept at the required temperature above its melting point by the oil-fired furnace. A shaft is mounted at one end in a bearing within the retort and at the other end in a bearing carried by the end of the retort. On it is fixed a left-hand screw-threaded cylinder (the conveyor) which is in mesh with a right hand screw (the spreader and scraper) of similar pitch and carried by a shaft mounted above the first.

PARLIAMENTARY INTELLIGENCE.

HOUSE OF COMMONS.

Progress of Bills.

Bills, as amended, considered, and to be read the third time: Barrow-in-Furness Corporation, Gas Light and Coke Company, Stockton-on-Tees Corporation.

Bill read the third time, and passed: Bolton Corporation.

The Standing Orders having been complied with, the Horley District Gas Company (Electricity Supply) Bill, and the Rochdale Corporation Bill are to be read a second time.

Gas Regulation Act.

In the House of Lords, on the motion of the Earl of Onslow (on behalf of Viscount Peel), the draft Special Order relating to the Gloucester Gas Light Company was agreed to. A similar motion was approved in the House of Commons on the proposition of Sir Burton Chadwick.

Copies were presented of drafts of Special Orders proposed to be made by the Board of Trade under the Act, on the application of the Brighouse Corporation, Pinner Gas Company, and the Yeadon and Guiseley Gas Light and Coke Company.

BARROW-IN-FURNESS CORPORATION BILL.

This Bill (see "Journal" for Jan. 21, p. 142) has been under consideration by the Local Legislation Committee of the House of Commons. The clause giving power to sell, let on hire, and maintain gas apparatus and fittings has been withdrawn by the promoters.

WESTMINSTER CITY COUNCIL (GENERAL POWERS) BILL.

This Bill was considered by the Unopposed Committee of the House of Commons (presided over by Mr. James F. Hope, Chairman of Ways and Means) last Wednesday, and ordered to be reported for third reading.

Originally, the Bill contained a clause enabling the City Council to construct subways; but petitions were deposited by the Gas Light and Coke Company, the Metropolitan Water Board, and Electricity Companies, on the ground of interference with their mains. Consequently the promoters withdrew the clause

MISCELLANEOUS NEWS.

IMPERIAL CONTINENTAL GAS ASSOCIATION.

Annual Report of the Directors.

The following is the report of the Directors for the year ended Dec. 31, which will be submitted to the proprietors at the 177th Ordinary General Meeting on May 13.

Of the agreed compromise in respect of the Association's German claims, a further instalment of 7s. 6d. in the pound on the outstanding balance has been received, and is incorporated in the accounts for 1924. The proportion of this instalment which represents realized accretion to capital, together with the undistributed balance of that account, amounts to £388,903 8s. 1d. The Directors recommend that this sum of £388,903 8s. 1d., being an accretion to capital which has been realized and turned into money, be dealt with as profit and applied in payment of a special dividend for the year 1924 at the rate of 19¼ p.ct. per annum on the nominal amount of the issued capital stock of the Association, payable on May 26.

The profit for the year (inclusive of the revenue proportion of the German claim instalment) is £230,628 4s. 1d., which, together with the sum of £45,951 0s. brought forward from the previous year's account, makes a total of £270,579 10s. 1d. available for appropriation, out of which an interim dividend of 5 p.ct. (actual), less tax, amounting to £76,570 12s. 9d., was paid in November last. The Directors now recommend that, in addition to the 19¼ p.ct. special dividend, there be also paid on May 26:

(*a*) A final ordinary dividend at the rate of 5 p.ct. (actual), less income-tax at 4s. 6d. in the pound, making the total ordinary dividend for the year 10 p.ct.

(*b*) A special bonus dividend, in celebration of the Association's centenary, at the rate of 5 p.ct. (actual), less income-tax at 4s. 6d. in the pound.

The sum of £46,867 11s. 10d. will accordingly remain to be carried forward to the next account.

The total output of gas in the towns supplied by the Association in 1924 was 5474 million c.ft., showing an increase at the rate of 5·3 p.ct. on the preceding year. The number of consumers on Dec. 31 last was 257,412, and shows an increase at the rate of 0¼ p.ct. in the year. The quantity of coal carbonized during the year under review was 316,200 metric tons, at an average gross cost per ton delivered on to the works of 27s. 2d., or 1s. 3d. per ton more than in the preceding year. The Droogenbosch electricity works at Brussels sold, during 1924, 21,574,759 KW.H., as compared with 16,031,129 KW.H. in 1923, an increase of 5,543,630 KW.H., or 34·58 p.ct. On Dec. 31, 1924, 1425 miles of gas mains and 547 miles of electric cables were in use, as compared with 1378 and 264 miles of mains and cables, respectively, on Dec. 31, 1923.

At Antwerp contracts giving the Association a gas monopoly until 1959 were concluded with the Communes of Halle (1060 inhabitants) and Merxplas (3067 inhabitants). At Brussels prolongations of contract for the supply of gas and electricity were secured at Linkebeek (3322 inhabitants) until 1945, at Uccle (35,755 inhabitants) until 1953, and at Woluwe-St.-Pierre (9917 inhabitants) until 1954. New contracts for the supply of gas and electricity were also concluded with the Commune of Schepdael (2234 inhabitants) until 1963, and with the Communes of Gaesbeek (376 inhabitants), Lennick-St.-Martin (1708 inhabitants), Lennick-St.-Quentin (2824 inhabitants), Lombeek-Ste.-Marie (709 inhabitants), Strijthem (847 inhabitants), and Wambeek (1782 inhabitants) until 1964.

At Antwerp the erection of three new naphthalene washers on the Berchem Works was completed. On the Hoboken Works the foundations of a new water gas plant were finished, and good progress was made with the erection of four new purifiers. A waste-heat boiler for the horizontal furnaces was also put into action with satisfactory results. Owing to the growth of business, the accommodation at the Cappellen District Office, near Antwerp, was found to be inadequate, and an additional plot of land was acquired. Moreover, in order to facilitate railway connection with the Association's site at Schooten, north-east of Antwerp, a strip of land was purchased there.

At Brussels, the renewal of six settings of vertical retorts on the Forest Works was almost completed, and eight settings of horizontals on the Koekelberg Works were reconstructed. Good progress was also made with the enlargement of the Chaussée d'Ixelles offices. At the Droogenbosch central station the extension of the buildings to house the new boilers and generators was completed, and two new turbo-alternators, one of 3750 KW. and the other of 10,000 KW., were put into action. The installation of a second 10,000 KW. turbo-alternator was also practically finished.

The gas-works at Bruex (a town of 27,000 inhabitants in Czecho-Slovakia), which were purchased by the Association in 1898, were ceded to the Municipality on Oct. 1 last, in accordance with the terms of the contract.

The Board regret to announce the death, on June 26, 1924, of Mr. H. G. Newton, who had been a Director since March, 1906. To fill the vacancy thus caused, Mr. George Jessel, M.C., has been elected to a seat on the Board. The Directors who go out of office by rotation are Colonel H. LeRoy-Lewis, C.B., C.M.G., D.S.O., Mr. Robert William Wilson, and the Rt. Hon. Sir Guy Douglas Arthur Fleetwood Wilson, G.C.I.E., K.C.B., K.C.M.G. They are eligible for re-election, and offer themselves accordingly. The Auditor who retires is Mr. C. F. Dendy Marshall, who is eligible for re-election, and offers himself accordingly.

(Signed) C. J. Jessel,
Chairman.

HONG KONG AND CHINA GAS COMPANY, LTD.

Annual General Meeting.

The Annual General Meeting of the Company was held at the Offices, No. 148, Gresham House, Old Broad Street, E.C., on Monday, March 30—Mr. Robert H. Glen, F.C.A. (the Chairman), presiding.

The Secretary (Mr. A. C. Pullen) read the notice convening the meeting and the Auditors' report.

The Chairman: Gentlemen, a copy of the report and statement of accounts having been sent to all the shareholders, I will ask you to take them as read.

Before I pass on to our ordinary business, you will perhaps permit me to refer to the fact that to-morrow is the first anniversary of Mr. Phillips' death. We miss his presence, but continue to benefit by the wise direction he gave to our affairs in his lifetime. You will have learned from the report of Mr. Wardrop's resignation from the Board. This was a cause of much regret to the other Directors, who tried hard to persuade Mr. Wardrop from taking such a step. Mr. Wardrop felt, however, that the time had come for him to give way to a younger man, and that his health would not allow of continued strain. The Board invited Major Heriot R. Glen, M.C., to fill the vacancy; and I will only say of him that he brings to our counsels keen business insight, as well as his lifelong family connection with the Company.

I referred last year to the fact that considerable additions had been, and were being, made to public lighting by gas in Hong Kong, and that our Engineer was trying hard to get back some of our lost lighting trade. I am sure it will be of interest if I mention the following figures for lighting appliances sold, supplied on hire purchase, or sent out on loan during the past year, exclusive of material for public lighting: "Surbiton," "Esher," "Pyrol," and other burners and lamps sold outright or on hire purchase, 911; supplied under the loan system, 1555. We also sold outright or on hire purchase 367 cookers, grillers, geysers, rings, &c., and supplied on loan 1040. It is a fact that the Company sold more gas stoves in six months of 1924 than in the previous six years. The Company have showrooms at Hong Kong Works, Kowloon Works, and at Messrs. Lane Crawford's, also a shop in the Wanchai district. We are negotiating with one of the largest Chinese firms in the Colony for them to exhibit our wares and help to push for gas business among the Chinese, who are large potential customers for the Gas Company.

The sales of gas increased at Hong Kong by 8·16 p.ct. and at Kowloon by 20·38 p.ct.; and I would like to emphasize to you that our private lighting trade went up by 10·16 p.ct. and public lighting by 11·29 p.ct. For years past we have endeavoured, from this side, to do all that was possible to retain and extend our gas lighting in Hong Kong; but you, as well as I, know that many people were obsessed with the idea that gas for lighting was either dead or dying. If this view was, and is, held, even by people in this country, you will, I think, agree with me that our present Manager is doing well in this branch of our trade at such a place as Hong Kong. Although Kowloon continues to develop, we are a little disappointed that our trade there has not made greater strides. At the present time a carburetted water gas plant is on order, and should be in operation before the end of this year to cope with the growing business. We have spent a good deal of money at Kowloon during the past five years—from 1920 to this date, about £45,000—but the Board feel sure this expenditure will bring good results.

The Directors were pleased to mention in their report that the cost of coal will show a large diminution for 1925. For some years we have considered the question of sending English coal to Hong Kong, and at the end of 1921 we had a cargo actually on order; but, after drastic reductions in the price of Yubari had been forced from this side, the cargo of English coal was cancelled. However, the advisability of trying good-class English coal has since been constantly before the Board, and during 1924 we made an experiment with 1500 tons of Yorkshire coal. The results obtained were, on the whole favourable, and a full cargo was sent out early this year. We have, in addition, contracted for Yubari coal to be supplied during 1925 at a very favourable rate. Indeed, I may say that four years ago it was costing us 100 p.ct. more than the price of to-day. I assure you, Gentlemen, that very strenuous endeavours have been made in this question of coal—one which is so vital to our Company.

Reference to our accounts will show that we have made additions to capital amounting to £8521, about one-half of which is for mains and services. We carbonized 1314 tons more coal in 1924 than in the previous year, and the extra cost for carburetted water gas is explained by the total output of it being one-third higher. Maintenance of retorts shows a considerable increase over 1923, accounted for by work done at both Hong Kong and Kowloon. The item in the balance-sheet for material used on vertical settings—viz., £3410—we propose to charge to revenue during the next three years. Other revenue debits show increases in consequence of larger trade, &c. Gas rentals advanced from $428,368 to $483,565—an increase of $55,197; and the figures for residual products total $68,922, as compared with $57,615. The estimated value of coke used on the carburetted water gas plant is credited here, our sales of coke really being very small. I mentioned last year that the Board were continually considering matters relating to our coke sales. At present our coke is disposed of entirely through the hands of a local contractor; but this has proved an unsatisfactory method, so the Company are at present engaged in trying to get the arrangement modified and, in due course, abolished. We hope, at no distant date, to be able to improve on the results shown. The amount of £1050 charged in the net revenue represents the vote made by you to Mr. Phillips' Executors for engineering work carried out by that gentleman over a course of twenty years, and the expenses connected therewith. I do not think further comment is needed on our accounts. The balance of net revenue amounts to £53,947, and a dividend for the year of 10 p.ct., free of income-tax, is recommended, less the interim dividend of 5 p.ct. paid in October, 1924.

The question of the purchase of our undertaking remains in *status quo*. Since the offer was received, our business has grown very much indeed; and I think our accounts for last year fully justify the line which the Board have taken in this matter, after prolonged and careful consideration. We hope for, and expect, far better results in 1925. If another offer for purchase is received, which is more in line with the value of our business and our properties, the Directors will place it before the shareholders.

Our Manager (Mr. Blackburn), in circumstances of considerable difficulty, has fully merited the confidence placed in him by the Board, and he is ably seconded by the other members of the staff. As from Jan. 1, the Board have inaugurated a bonus on profits scheme, by which all the local staff and workpeople will benefit, from the Manager to the lowest workman. A provident scheme has also been instituted, and to this all the European members of our staff have signified their intention to contribute a portion of their pay. Before I conclude, I may mention that my colleagues on the Board have requested me to visit Hong Kong again, in order to deal with some important outstanding matters. I leave for the East immediately. With these remarks, I have pleasure in moving that the report and accounts be received and adopted.

Mr. Strachan C. Clarke seconded the resolution, which was carried unanimously.

The Chairman moved the following resolution:

> "That a dividend at the rate of 10 p.ct. per annum, free of income-tax, be declared for the year ended 31st December, 1924, less interim dividend paid 1st October, 1924; the warrants to be made payable on the 9th April."

This was seconded by Major Heriot R. Glen, and unanimously carried.

The Chairman then proposed the re-election of Mr. Strachan C. Clarke as a Director of the Company, which was seconded by Mr. Leonard Askew, and carried unanimously.

In returning thanks, Mr. Clarke referred to the many problems with which in recent years it had been necessary to deal, and stated that he believed the Company had a prosperous time now before them.

Mr. John G. Wardrop moved the re-election of Messrs. Cash, Stone, & Co. as Auditors for the current year.

This was seconded by Mr. John M'Cubbin, and carried unanimously.

The Chairman proposed a vote of thanks to the staff in Hong Kong and London, which was seconded by Mr. John M'Cubbin, and, after being warmly supported by Mr. John G. Wardrop, was unanimously carried.

The Secretary responded; and the proceedings terminated.

GAS REGULATION ACT APPLICATIONS.

The following notice has appeared in the "London Gazette" regarding an application to the Board of Trade under the Gas Regulation Act.

SPECIAL ORDER.

Croydon Gas Company.

Application is to be made by the Company for an Order under section 10 to enable them to acquire scheduled land for gas-works purposes; to raise additional capital; to make further provisions with regard to the supply of gas; and for other purposes.

HAYWARD'S HEATH DISTRICT GAS COMPANY.

The Annual General Meeting of the Company was held on Friday, April 3—Mr. E. C. Charleton, Chairman, presiding.

In the report for the year ended Dec. 31, it was stated that the balance of the profit and loss account was £6267. It was proposed to pay a final dividend at the rate of 7½ p.ct. per annum on the 5 p.ct. consolidated stock for the half-year to Dec. 31, making 7½ p.ct. (less income-tax) for the year. The balance to be carried forward was £4242.

The Chairman, in moving the adoption of the report and accounts, said that the total quantity of gas sold during the year was over 77 million c.ft.—an increase over 1923 of 11·8 p.ct. During the year the price of gas had been reduced by 1d. per therm. Rental of meters and fittings showed a satisfactory increase. The Directors had placed a further £500 to the contingency account, bringing it up, with reserve, to the satisfactory figure of £4200. The repairs suspense account had also been added to, to the extent of £500. Negotiations which had spread over a number of years in a rather desultory manner with the Cuckfield Gas Company, for the purchase of the latter's undertaking, reached a satisfactory conclusion; and a purchase figure was agreed upon. The undertaking was taken over on Jan. 1, 1925. The satisfactory results obtained by their Company were due to a large extent to the ability of their Engineer, Manager, and Secretary, Mr. A. E. Whitcher.

At the conclusion of the annual meeting an extraordinary general meeting was held for the purpose of passing resolutions authorizing the Directors to raise a sum not exceeding £23,500 by the issue of debenture stock.

The Chairman, in moving the resolution, said it was only right that they should pay by capital for the Cuckfield Company; and as they had to supply Cuckfield, it would be necessary to erect another gasholder.

The resolution was carried.

The Hereford City Council have approved of a recommendation of the Gas Committee to borrow the sum of £3500 for the purpose of installing prepayment supplies.

LONDON COUNTY COUNCIL AND THE PRICE OF GAS.

At last week's meeting of the London County Council—Captain O. E. Warburg (Chairman) presiding—Mr. M. H. Davis (Whitechapel and St. George's) asked the Chairman of the Public Control Committee the following questions:

Commercial Gas Company.

(1) Whether his attention has been called to the fact that the Commercial Gas Company intend increasing the price of gas supplied by them, as from Lady Day, by as much as 2·85d. per 1000 c.ft., thereby bringing the price of their gas to as much as 3s. 8·65d. per 1000 c.ft.?

(2) Whether he is aware that one of the remarkable reasons given for the increase is that the price obtainable for coke has dropped?

(3) In view of the fact that the area supplied by the Company includes a large number of poor people, who will be severely hit by such increase, will he state what steps the Committee intend to take in the matter?

Mr. Cyril H. M. Jacobs (Clapham), the Chairman of the Public Control Committee, said in reply:

(1) The answer to the first question is in the affirmative.

(2) The increase is stated to be due to a reduction in the prices obtainable for residual products (coke, tar, and ammonia), and to increases of wages. The same reasons have been given by other gas companies for increases of price to be made as from Lady Day. There is nothing remarkable in the reasons given for the rise in price, as, owing to the increased production in the mining areas of France and Germany, a drop in the price of coke has actually occurred.

(3) The Council in 1924 made an application to the Board of Trade under the Gas Regulation Act, 1920, for the reduction of the standard price of gas applying to the Commercial Gas Company, in view of the fall in cost of production in recent years; and the standard price was accordingly reduced, as from June 30, 1924, from 15·4d. per therm to 11·4d. The effect of this reduction was that the authorized dividends payable by the Company were considerably reduced. The Company are within their statutory rights in increasing the price of gas, and no further action by the Council is possible in the present circumstances. By means of the sliding-scale, however, the interests of the shareholders are identified with those of the consumers; and the present increase in price will automatically involve a reduction of the dividends payable for the current year.

Mr. Davis: Can I ask the Chairman of the Public Control Committee when the increase in the wages of the workmen will take place?

Mr. Cyril Jacobs: I cannot answer that question. I do not know.

South Metropolitan Gas Company.

On the presentation of the report of the Public Control Committee relating to the South Metropolitan Gas Company's basic price, which was reproduced on p. 131 of the last issue of the "Journal,"

Mr. J. D. Gilbert, D.L., J.P. (Central Southwark), said he wanted to raise a point as to whether anything further could be done beyond what was reported by the Committee. It was reported that the South Metropolitan Gas Company were increasing the price of gas from 8d. to 8¾d. per therm. To the small consumers, and to a great many of the consumers who used the slot meter, he believed this would work out at an even higher rate than the 8¾d. per therm. He would like to ask the Chairman whether, in conjunction with this report, he had had any report as to the great slump in the price of coal which had occurred during the last fortnight. The price of coal had slumped very considerably—almost as much as from 3s. to 4s. a ton in some cases—and in view of this he would like to ask the Committee to consider whether the Gas Company were entitled to increase the charge for gas to the price they now proposed. There was a general impression outside the Council that there was some kind of appeal from a gas company's prices to the County Council. From this report, he did not gather that the Committee had dealt with that matter. Was there any method by which consumers could have the right of appeal to the Council as to whether the prices charged, not only by this particular Company, but by all other gas companies in London, were right and legal? If it was so, he thought it would be found that a good many consumers in South London would take advantage of the opportunity to come to the Council to know whether the Company were entitled to make this extra charge.

Mr. Cyril Jacobs replied that perhaps it would be well if he explained the different position of the South Metropolitan Company from that of other large companies who supplied in the London area. Whereas the South Metropolitan Company came under their own Act of 1920, all the other companies came under the Gas Regulation Act of the same year. At the instigation of the Council, applications were recently made to the Board of Trade for a revision of the standard or basic price in respect of the four largest Companies. The case of the South Suburban Gas Company was under consideration at the present moment. As a result of inquiries made by the Board of Trade, the standard price in pence per therm was reduced in each instance, as follows:

	Pence per Therm.
Gas Light and Coke Company . . .	from 15·2 to 11·0
Commercial Gas Company	,, 15·4 ,, 11·4
Wandsworth Gas Company	,, 16·6 ,, 14·0
Brentford Gas Company	,, 17 8 ,, 14·0

It would be noticed that the lowest standard price was fixed in respect of the Gas Light and Coke Company in 1924, and that this price was 11d. per therm. Under the South Metropolitan Gas Act of 1920 the standard price was fixed by Parliament at 11d. per therm—exactly the same as the lowest price fixed by the Board of Trade, in respect of the Gas Light and Coke Company—and in that Bill the Council had the right to go to Parliament in the present session to ask for a revision of the standard or basic price.

Mr. Gilbert: The Council or the Company?

Mr. Jacobs: The Company have to go, and the Council have a right to contest it. Continuing, he said that the Comptroller had conducted a very full inquiry into this question, which had been the subject also of a special meeting of the Public Control Committee. It appeared desirable that the statutory basic price should be brought into line with present costs; and action was being taken with a view to effecting this in connection with the Company's Bill now before Parliament. At Michaelmas, 1922, the South Metropolitan Company were charging 11¾d. per therm for their gas, but by Michaelmas, 1923, had reduced it by various stages to 8d. The Company were now giving notice of an increase of price by ¾d. per therm, and one could presume that this was to make income balance with expenditure. The Commitee were advised by the Council's officers that in their opinion the Company were quite justified, in the present circumstances, in making this increase. The price of gas must always be determined by the cost of production, and—another very important point—by the prices obtained by the sale of coke and other bye-products from the manufacture of coal gas. They had been told that there was going to be an increase in wages; and he understood that this was going to take place from the 1st of next month. It had been established that these Companies were receiving very much lower prices by the sale of their coke and other residuals, owing to the increase of mining and trade developments in France and Germany. He thought they must therefore be prepared for a general small increase in the price of gas in the near future. The interests of the consumers were adequately protected by the sliding-scale, under which the dividends payable were limited to a fixed figure so long as the price charged for gas was not less than the standard price fixed by Parliament; and the payment of any additional dividends must be accompanied by a proportionate reduction in the price charged for gas. By means of the sliding-scale, the interests of the shareholders were identified with those of the consumers; and it was in the interest of the Company, no less than in that of the consumer, that the price should be kept down.

The report was received.

Birmingham Gas Department.

The Birmingham Gas Committee in a report to the City Council refer to the subject of gas supplies to small house property in courts and terraces. Considerable progress had been made in the lighting of courts and passages themselves, and in the provision of slot meter installations, though there were still many courts, particularly in the poorer parts of the city, which had no gas supply. There was less reluctance on the part of landlords to pay the cost of "carcassing" a house with internal piping, which costs, on an average, about 45s. per house. In 1922, 370 such houses were dealt with; in 1923, 535; and in 1924, 1155. Housing developments were sufficient to keep all the available gasfitters fully employed, and the Gas Committee considered it would be unwise to contribute further towards the cost of installing gas in existing small house property. The present practice is for the Department, at their own expense, to lay the main supply pipe from the street, after a house has been "carcassed;" and a concession is also made in the cost of the service pipe therefrom to the meter—only a nominal sum of 2s. 6d. per house being charged against the property owner. By arrangement, however, the cost of installations to property owners may be spread on the instalment principle over a period not exceeding five years. Branch depôts and offices are to be opened at Acocks Green and Erdington, and at each a number of gasfitters and one or two clerks will be stationed. A recommendation is made by the Gas Committee in favour of the purchase of six small Wolseley two-seater motor cars for the use of mains inspectors.

Wells Gas Light Company.—Messrs. A. & W. Richards have been instructed by the Directors of the Company to offer for sale by tender £8000 6½ p.ct. irredeemable preference stock; the minimum price being par. It will have been seen from the announcement appearing in our advertisement pages that tenders should be forwarded to Messrs. Richards, No. 37, Walbrook, E.C. 4, not later than eleven o'clock on Tuesday, April 21.

Bridgwater Gas Light Company.—When reporting the results for the year 1924, the Directors were able to point to an increase of about 2⅝ million c.ft. in the sales of gas, and to a further reduction to 11·11d. per therm (or 4s. 2d. per 1000 c.ft), which is less than 40 p.ct. above the pre-war charge. At the meeting, the Chairman (Mr. R. Y. Foley) remarked that the results were again very satisfactory; over 15,100 c.ft. of gas being made per ton of coal carbonized. Mr. Cornish, Jun., has been appointed Works Manager; while Mr. J. H. Cornish continues to render valuable service to the Company as Manager and Secretary.

Torquay and Paignton Gas Company.—Presiding at the annual general meeting of the Company, Major R. P. Kitson (Chairman of Directors) said the revenue account fully justified the amalgamation between the Torquay and Paignton Companies. The sales of gas had increased wonderfully—the total increase for the year being 31 million c.ft. No fewer than 369 millions had been sold. The necessary plant for effecting and carrying on the entire manufacture of gas at the Hollacombe Works would be in complete operation before the next annual meeting. The increased demand for gas showed every sign of continuing, as the district was rapidly developing in all directions. With regard to residuals, it was satisfactory to note that the sales under this heading had realized 64 p.ct. of the cost of coal. Continued progress was also received in the sale of fittings. The shareholders and the public would shortly receive notice of the intention to issue for sale by tender debenture stock in the Company. The accounts, which showed a disposable balance of £21,688, were passed, together with a dividend at the rate of 6 p.ct. per annum upon the ordinary stock, less income-tax.

NORTH-EAST COAST COAL TRADE.

From our Own Correspondent.

There is an entirely featureless market, with holiday conditions and continued absence of forward inquiry.

Wear Special makes indicate 20s. f.o.b., and best qualities 19s. 6d. to 20s. Seconds and others are 17s. to 17s. 3d

YORKSHIRE AND LANCASHIRE COAL TRADE.

From our Local Correspondent.

The situation in the coal trade in Yorkshire and Lancashire remains practically unaltered from that of last week. Gas coals are moving steadily under contract. Prices are also about the same. For prompt account, best hards have been sold at 19s. 3d. to 19s. 6d. per ton f.o.b., and secondary sorts showed little recovery from the depression. There is no improvement in the export sections, Continental competition remaining keen. Washed doubles are quoted at about 17s. to 17s. 6d. per ton f.o.b., and singles about 17s. 6d. The home inquiry for all kinds of industrial fuel remains small.

COAL TRADE IN THE MIDLANDS.

From our Local Correspondent.

A very gloomy view is taken of the outlook in the Midland coalfields, on account both of the immediate effects of a shrunken turnover and the large implications of the crisis in an economic sense. It is feared it must prove disastrous for many of the less favourably situated undertakings, and seriously aggravate unemployment. A decision has been taken to close the Great Wyrley Colliery—till recent years one of the most prosperous mining properties on Cannock Chase. The pitmen to the number of about 640 have received notice to terminate their engagements this week. Future policy is being anxiously considered by a great many managements, since it is evident that unless demand expands, of which there is little expectation at present, collieries which are relatively expensive to work, and which have no sufficient non-competitive distributive radius, cannot hope to hold their own against big concerns with rich deposits worked with all the labour-saving resources of modern equipment.

The market for gas coal is stagnant and featureless. Steams and all qualities of industrial fuel are in abundant supply. The trade has been very inactive during the past fortnight. Very little coal is being raised this week. With considerable stocks in hand, the resumption will be irregular. Market values are very unstable.

CONTRACTS OPEN.

Coal.

The Directors of the Otley Gas Company are inviting tenders for the supply of 5000 to 7000 tons of best screened gas coal or nuts. [See advert. on p. 194.]

EXTENSIONS.

New Retorts for Oswaldtwistle.

The Oswaldtwistle Gas Committee are applying to the Ministry of Health for sanction to borrow £21,000 for new retorts.

Light and a Shopping Week.—At a special meeting of all traders interested in a shopping week proposal at Bradford, held under the auspices of the Bradford Chamber of Trade, Mr. S. H. Packer, Sales Manager to the Bradford Corporation Gas Department, strongly supported the proposal, and said his Department would help in every way possible. He suggested that the period should be a fortnight, instead of a week; and in this proposal he was supported by several other speakers. At the same meeting Mr. C. E. Allsopp, Sales Manager to the Bradford Electricity Department, said he believed traders for that period would be allowed electricity for lighting at 1½d. per unit (the present price charged for window lighting after shop hours), instead of the normal price of 7d. per unit.

Illuminated Signs Association.—An Association of Users and Manufacturers of, and Traders in, Illuminated Signs has been formed, with offices at No. 25, Victoria Street, Westminster, "to watch the proceedings of Parliament and Government Departments for the purpose of protecting the interests of its members against restrictive legislation; to safeguard those interests against excessive rating and prohibitive by-laws proposed by local authorities; and to take action in matters of a legal character in which its members may be involved within the functions of the Association." The Association is opposing the action of a municipal authority in seeking powers to prohibit the use of illuminated signs, since, if these powers are obtained by one Corporation, other local bodies will make similar applications, with the result that the industry will be completely crippled, and a valuable advertising medium lost.

Devon Gas Association.—The 19th annual meeting of the Association was held on April 2, at Exeter. The Chairman (Mr. F. T. Depree, J.P.), in moving the adoption of the report, said that during the year the price of gas had been generally reduced, but the increase in output had more than made up for this. The Moretonhampstead Works had recently been much improved by the addition of new storage accommodation and carbonizing plant, while the freehold of the site had been acquired. Perhaps the most important event of the year was the acquisition of the Ivybridge gas undertaking. This was situated in a thriving district, and he looked forward to its becoming a valuable addition to the Association. The decrease in the value of all gas-works residuals was a matter of some concern in the coming year; but he hoped that it would not be necessary to increase the price of gas. Mr. R. I. Rew, seconding, referred to the structural improvements and additions to the various plants at their several works. The report was adopted, and a 7½ p.ct. dividend, less income-tax, was declared.

CURRENT SALES OF GAS PRODUCTS.

The London Market for Tar, Tar Products, and Sulphate.

London, *April* 13.

Business in the London tar products market is very quiet at present, which is to be expected during the holiday week. Prices are unchanged.

Tar Products in the Provinces.

April 14.

Markets generally remain dull, and there is nothing of interest to report.

Pitch is still neglected. Some business has been done on the Continent on the basis of 40s. f.o.b. U.K. ports; while South Wales have refused offers at equal to 35s. f.a.s. Manchester. The present low price makes forward business impossible. Consumers refuse to pay any advance on prompt prices; while makers, quite naturally, feel they can do no harm by waiting.

Creosote is quiet, but the undertone is steady; and it is confidently expected that before long export orders for July-December will come into the market.

Benzoles are steady, solvent naphtha firm, carbolic and cresylic dull, and naphthalene and anthracene almost unsaleable.

The average values for gas-works products during last week were: Gas-works coal tar, 28s. 6d. to 33s. 6d. Pitch, East Coast, 40s. to 41s. f.o.b. West Coast—Manchester, 35s. to 30s.; Liverpool, 30s. to 37s.; Clyde, 39s. to 40s. Benzole, 90 p.ct., North, 1s. 6½d. to 1s. 7½d.; crude, 65 p.ct., at 120° C., 7½d. to 8¼d., naked at makers' works; 50-90 p.ct., naked, North, 1s. 6½d. to 1s. 7½d. Toluole, naked, North, 1s. 6d. to 1s. 7d., nominal. Coal-tar crude naphtha, in bulk, North, 7¾d. to 8¼d. Solvent naphtha, naked, North, 1s. 5d. to 1s. 6d. Heavy naphtha, North, 1s. to 1s. 2d. Creosote, in bulk, North, liquid, 6¾d. to 6¾d.; salty, 6d. to 6¼d.; Scotland, 5⅞d. to 6¼d. Heavy oils, in bulk, North, 6¼d. to 7d. Carbolic acid, 1s. 5d. to 1s 6d. prompt. Naphthalene, £11 to £14; salts, £4 to £5, bags included. Anthracene, "A" quality 2½d. per minimum 40 p.ct., purely nominal; "B" unsaleable.

Social Side of Messrs. W. J. Jenkins & Co., Ltd., Retford.

Much has been written on the primary duty of employers in every industry to diffuse the proper atmosphere of sociability and goodwill around their managerial staff and employees, and quite a lot of valuable data have been compiled from large concerns where this atmosphere has been created. Fortunately it requires little search to recognize the chief factors which go so far towards completing this most desirable unity. Three of them are undoubtedly the spirits of recreation, sport, and harmony. The times demand that work and play shall run hand in hand; and the really modern employer—keen psychological student that he usually is—fully recognizes this combination, and gives the matter his wholehearted support. An example of this was recently to be found in the Town Hall, Retford, when a delightful evening was spent under the auspices of the Beehive Works Sports Club of Messrs. W. J. Jenkins & Co., Ltd. Nearly 800 were present at the entertainment, which was of an unusually high order, and was provided by the members of the Social Section in the form of an original revue entitled "The Belles of Honolulu" or "The Blue Lagoon." This revue was specially written and produced by a talented member of the staff, who was also responsible for the painting of the beautiful scenery, kindly presented by the management. The artistes were mainly drawn from the various departments and workshops of the firm. The consensus of opinion was that it was one of the most brilliant and inspiring shows ever put on the local platform. After the revue, there was dancing.

Increased Consumption at Oldbury.—At a meeting of the Oldbury District Council last week, Mr. K. H. Wilson (the Chairman of the Gas Committee) referred to the fact that during the year ended March 31 210 million c.ft. of gas had been consumed, compared with 191 million c.ft. in the previous year—an increase of over 10 p.ct.

Australian Gas Light Company.—It has been decided by the Directors to dispense with the printing of a half-yearly balance-sheet and report, and to substitute for them an annual balance-sheet and report for the Company's year ending June 30, for presentation at the statutory annual meeting to be held in August. A dividend of 4 p.ct. for the past six months was declared, leaving a balance to be carried forward of £50,530.

Prepayment Consumers at Glasgow.—Councillor Hanlon has given the Glasgow Corporation Gas Committee notice that, at the next meeting, he will move: "That it be remitted to a Special Sub-Committee to consider and report as to the advisability of increasing the number of prepayment meters already in use, or alternatively considering some means of restoring the supply to householders who have had the supply cut off through inability to pay their gas accounts."

Reduction in Price at Neath.—The Neath Town Council, at their last meeting, adopted a recommendation of the Gas Committee to reduce the price of gas, as from the March quarter readings, by 1d. per therm (equivalent to 4¼d. per 1000 c.ft.). This reduction follows upon one of 2·1d. per therm (equivalent to 8·925d. per 1000 c.ft.) which came into operation as from the March quarter readings, 1924. During the past year, the Neath Gas Department have closed down the Briton Ferry Works, which were taken over at the time of the Neath borough extension; and the whole of the gas for the extended area is now being supplied from the Neath Works. These works have been considerably remodelled and extended during the past three years; and the economies effected are now showing in the reduced price for gas. A Sports and Recreation Club has recently been organized; and the work of laying down a bowling green, tennis court, &c., on the spare land adjoining the gas-works is being proceeded with. A recreation room, including mess room, bath room, &c., was formally opened by the Mayor about three weeks ago.

STOCK MARKET REPORT.

The only redeeming feature on the Stock Exchange last week was the success of the new issues. The principal of these was the Municipality of Danzig loan for £1,500,000, which was considerably over-subscribed. A premium of 1⅞ was quoted at first, but the efforts of the "stags" to unload before the holidays brought this down rapidly to ¾ premium. There were several other issues, including the London County Freehold and Leasehold Debentures and the Burndept Wireless Preferred shares, all of which, being regarded as fairly good purchases, were successfully floated. Otherwise, with perhaps the exception of the usual popular shares, there was a total lack of business; the public, intent on holidays, giving little attention to stocks and shares.

The outlook is still dominated by the position in France, which is very uncertain, and it is not relieved by the announcement at the week-end of the Premier's resignation, the effect of which will doubtless be noticeable when the markets reopen. It is feared the news will accentuate the present depression, especially on the Foreign Market.

In the Gas Market there was no exception to the general rule, although there were fewer changes in the quotations. Gas Light ordinary fell another 1⅛ points to 86-89. The announcement of the Company's intention to raise the price of gas as from June next, bringing in its train a reduction in the authorized dividend, will not tend to improve the price. It must be remembered, however, that a reduction of dividend is not compulsory until February of next year, when, subject to the price of gas not having been still further increased, the authorized rate payable will be £4 17s. 4d. p.ct. per annum, which is the same rate that was paid immediately pre-war.

The Commercial Gas stocks are now quoted at 88-91 and 87-90 for the 4 p.ct. and 3½ p.ct. stocks respectively. The authorized dividends on these stocks payable in August next are £5 6s. 8d. and £5 3s. 4d. p.ct. per annum, which rates are slightly less than the pre-war dividends.

The following transactions were recorded during the week:

On Monday, Aldershot "C" 78¼, 4 p.ct. preference 72½, Commercial 3½ p.ct. 87. Continental Union 7 p.ct. preference 90¼, East Hull (5 p.ct. max.) 86½, 86⅞, Gas Light and Coke 88½, 88⅞, 88⅞, 89, 89¼, 4 p.ct. preference 78⅞, 79½, 3 p.ct. debenture 60, 61. Imperial Continental 180, 181, Primitiva 8s. 0d., 8s. 0½d., 8s. 10½d., 8s. 11½d., 4 p.ct. debenture (1911) 63½, South Metropolitan 94½, 95¼, Tottenham "A" 118½, "B" 98, 99. Supplementary prices, Brentford 6 p.ct. mortgages 100.

On Tuesday, Aldershot "C" 78¼, 79½, Alliance and Dublin 66½ *ex* div., Brighton and Hove 169, 170, Bristol (5 p.ct. max.) 93½, British 112, Commercial 4 p.ct. 88, 3½ p.ct. 87, 3 p.ct. debenture 58⅝, 60, Continental Union 37, European 7⅜, Gas Light and Coke 88⅛, 88⅛, 88⅞, 89¼, 89⅝, 3½ p.ct. maximum 63, 63½, 63⅜, 3 p.ct. debenture 60, 60⅛, 60⅞, 61, Imperial Continental 179½. Primitiva 8s. 0d., 8s. 7½d., South Metropolitan 94½, 95¼, 6½ p.ct. debenture 103, South Suburban 5 p.ct. 98, 101½. Supplementary prices, Dover 5¼ p.ct. debenture 102½, 102⅝, Hartlepool 5 p.ct. maximum 89⅜, Wandsworth 3½ p.ct. new 95.

On Wednesday, Aldershot "C" 70½, Bombay 5½, £5 3s., Commercial 4 p.ct. 87, 3½ p.ct. 87, European 7⅛, Gas Light and Coke 88⅜, 88½, 88⅞, 89, 89¼, 4 p.ct. preference 78½, 79⅛, Imperial Continental 179, 180, Primitiva 4 p.ct. debenture (1911) 64½, South Metropolitan 94½, 3 p.ct. debenture 60½, 61½. Supplementary prices, Dover 5¼ p.ct. debenture 102½, 102½, North Middlesex 5 p.ct. preference 90½, 91.

On Thursday, Bombay 5¼, Bournemouth "B" 12⅜, Continental Union 36⅛, Gas Light and Coke 87, 87⅛, 88, 88⅛, 88⅜, Imperial Continental 180½, 182, 182½, Montevideo 65⅝, Primitiva 4 p.ct. debenture 64, 65, South Metropolitan 95, 95¼, Wandsworth "B" 113⅜, 114. Supplementary prices, Liverpool 5 p.ct. 87½, Newport (Mon.) 5 p.ct. maximum 84, Wandsworth 5 p.ct. preference 95.

The Money Market also bore signs of the holiday atmosphere, and rates were quiescent. Discount quotations were possibly easier, due doubtless to the low rate at which Treasury Bills were allotted. The average rate was £4 3s. 4·18d. p.ct., or 2s. 3d. below that for the previous week. The new Treasury Bills were dealt in at 4½ p.ct. Money was fairly plentiful on Thursday, and rates for fresh accommodation declined to 3 p.ct., but rather tighter conditions prevailed on Saturday.

In the Foreign Exchange Market on Thursday the Paris cheque moved against France, rising at one time to 93.40; but on Saturday, in spite of the political disturbances, the rate improved to 92.45 to the £. Belgian francs moved in sympathy to 94.45. Sterling on New York was weaker at 4.76⅛ dollars, and Italian lire rather cheaper to 116.40.

The Silver Market was quiet, the price for cash being 31½d. per oz. Gold was 1d. down on the week at 86s. 5d. per oz.

The Bank Rate is 5 p.ct., to which it was raised from 4 p.ct. on March 5. Bankers' deposit rates are 3 p.ct. The deposit rates of the discount houses are 3 p.ct. at call and 3¼ p.ct. at notice.

THE FLOW OF GASES and PROPORTIONING GAS MAINS.

By

F. SOUTHWELL CRIPPS, Assoc.M.Inst.C.E.

WALTER KING, Ltd., "Gas Journal" Offices, No. 11, Bolt Court, Fleet Street, E.C.4.

Infringing the Municipal Corporations Act.—Mr. S W. B. Stephen, the Chairman of the Gas Committee of the Smethwick Town Council, who was recently disqualified through having dealings in coke with the Gas Department, has again been elected to the Town Council.

Leamington Priors Gas Company.—Presiding at the annual meeting of the Company, Dr. Harold Mason expressed the opinion that the reduction in the price of gas, bringing it down to 8¾d. per therm, had been justified. This was shown by an increase of 3½ million c.ft. in gas sales. They were recommending the payment of the usual dividends, but they had had to reduce their carry-forward.

An Address on Gas Undertakings.—At a recent meeting of the Dudley Rotary Club, Mr. G. E. Ashurst, Secretary of the Dudley Gaslight Company, read a paper on "The Distinctive Features of Statutory Undertakings, with special reference to Gas Undertakings." Mr. Ashurst, in the course of his remarks, referred to the popularity of gas for public street lighting, mentioning that a census of 1000 cities and towns in the United Kingdom resulted as follows: Out of 670,300 lamps, 585,600 were gas—or 87 p.ct.

Tavistock Lighting, Coal, and Coke Company, Ltd.—At the annual meeting of the Company—Mr. T. Doidge presiding—the report of the Directors stated that the output of gas had increased, and that the sales were 9 p.ct. above those for 1923. Residuals also had yielded a satisfactory return. The mains in various parts of the town had been enlarged to meet the increasing requirements. The balance at the credit of the profit and loss account, after providing for income-tax and the payment of an interim dividend, was £1081. The report and statement of accounts were adopted. It was resolved that a final dividend be declared at the rate of 4 p.ct. (less income-tax) for the half-year ended Dec. 31, 1924, on the original capital, and £2 16s. p.ct. on the additional capital.

Limerick Gas-Works Improvements.—The Free State Ministry of Industry and Commerce have informed the Limerick Corporation, in relation to the latter's application for a loan of £30,000 for carrying-out improvements in the city gas concern, that the men displaced by the introduction of new machinery will have their claims for compensation favourably entertained by the Ministry, and that it is the intention of the Local Government Ministry to introduce legislation empowering local authorities to make provision for granting pensions to employees in the gas and other sections. The Corporation Law Adviser reported on his interview with the Minister in regard to the men who would be unemployed through the gas-works improvements, and said they would receive gratuities and pensions. This was considered satisfactory.

Lighting at Northampton.—At a recent meeting of the Northampton Corporation Highways Committee, the Borough Engineer submitted communications from the Northampton Gaslight Company on the question of street lighting. The Company pointed out that at present 1304 public street lamps were lighted, and the annual costs (£6044) were proportionately high as compared with the cost of lighting the whole of the lamps in the borough—viz., 1764. The cost of lighting the 1764 lamps would be £7757; but in the event of such lamps being lighted, the Company were prepared to reduce the annual charge to £7150. They also suggested that a new contract for a period of seven years (instead of five, as at present) should be entered into. The Committee resolved that a contract in accordance with the terms set out above should be made.

Further Capital for the Barnet Company.—The Directors of the Barnet District Gas and Water Company are inviting tenders for £15,000 of "D" capital gas stock, ranking equally with the existing similar capital now receiving the maximum dividend of 7 p.ct. per annum. The minimum price of issue is £110 per £100. Tenders must be received by the Secretary of the Company, at No. 139, Cannon Street, E.C., not later than Monday morning, April 20.

Gas Light and Coke Company's Price Increase.—The Directors of the Gas Light and Coke Company regret to have to announce that the price of gas throughout the Company's district will be increased from 8·6d. per therm (3s. 7d. per 1000 c.ft.) to 9·4d. per therm (3s. 11d. per 1000 c.ft.), as from the date of recording the meter indices for the June quarter. This advance in the price of gas will necessitate a reduction in the Company's dividend. The price of the Company's gas was steadily reduced from the end of 1921 till June, 1923, when it reached its present low figure; and an increase in the price is now rendered necessary by the serious reduction in the revenue derived from coke and other residual products, and by the increase in wages paid since the beginning of the present year. The consumers are assured that the price is not being raised more than is absolutely necessary, and that it will be reduced at the earliest possible moment.

Steam Raising Problems.—On Monday evening, March 30, Mr. A. Whatmore, A.M.I.M.E. (Works Manager of Messrs. Parkinson and W. & B. Cowan, Ltd., Victory Works, Manchester), gave a lecture before the North-Western Section of the Junior Institution of Engineers, on "Steam Raising Problems." He discussed various forms of firing, including gas firing, and mentioned, in making a forecast of the future, that the day would come when there would be super-gas stations, in a similar manner to the super-electricity stations now being built. This would allow of all coal being gasified, the bye-products sold, and gas supplied to manufacturers for steam raising, and also the supplying of gas to super-power stations either for firing the boilers to produce the steam for turbines or for gas engines. This would result in considerable economy in regard to production, and also eliminate to a certain extent the smoke problem. A good discussion followed the lecture.

The Directors of the Abergele and District Gas Company have decided to reduce the price of gas at an early date by 7d. per 1000 c.ft.

To bring home to local allotment holders and others the use of sulphate of ammonia as a fertilizer, the Burnley Gas Department are making a demonstration in their showroom. The display is arousing much interest.

Alderman Aspinall, speaking on the occasion of "budget day" in the Bolton Town Council, said it was gratifying to note that the gas undertaking was likely to finish the financial year considerably better than was anticipated twelve months ago.

At a meeting of the Blackpool Town Council, on April 1, Alderman Broadhead said they had £10,872 to the credit of reserve on the gas undertaking. This he regarded as insufficient, and for this reason it was proposed to place the whole of last year's profits, and unappropriated balance for the previous year, to the improvement of this reserve. He said that there had been considerable development in the gas undertaking; the consumers having increased from 21,280 to 22,606—equivalent to 6 p.ct.

PATENTS and Trademarks. Inventors' Advice, Handbook and Cons. free. B. T. KING (Regd. Patent Agent, G.B., Canada and U.S.A.), 146A, QUEEN VICTORIA STREET, LONDON. 38 years' refs. 'Phone 682 Cent.

APPOINTMENTS, &c., VACANT.

WHEN Filling Vacancies, please REMEMBER THE CLAIM OF THE EX-SERVICE MAN, who, other Qualifications being equal, HAS THE FIRST CALL ON YOUR CONSIDERATION.

FITTINGS FOREMAN.
(HALIFAX GAS DEPARTMENT.)

WE wish to Thank all who replied to our Advertisement. AN APPOINTMENT HAS BEEN MADE.
April 6, 1925.

ASSISTANT Engineer required for Gas-Works Abroad. Applicants must be fully Trained in Modern Methods and capable of Taking Charge during absence on leave of General Manager. Good Business Ability and Control of Labour essential. Age 25 to 35. Five years' Agreement. First-class passage out and home.
Applications, stating Age, Qualifications, and Experience, and whether Married or Single, with *copies* (not *originals*) only) of Testimonials as to Character and Qualifications, to No. 7536, "GAS JOURNAL," 11, BOLT COURT, FLEET STREET, E.C. 4.

AGENT for Australia required with Gas Company Connection to REPRESENT Established British Firm Manufacturing Gas-Meters and Repair Parts of New and Patented Design.
Apply No. 7535, "GAS JOURNAL," 11, BOLT COURT, FLEET STREET, E.C. 4.

CHIEF Works Foreman required by the Reading Gas Company. A good Wage will be paid and a House with Coal and Gas provided. Only those who have had an all-round Experience should apply.
Applications, stating Age and Experience, to be sent to the ENGINEER, GAS-WORKS, READING, as soon as possible.

LARGE Firm of Gas-Works Plant Manufacturers require the Services of Two Experienced and Responsible DRAUGHTSMEN used to Gas-Works and Chemical Plant.
Full Details of Experience, Connection, Salary required, &c., to No. 7537, "GAS JOURNAL," 11, BOLT COURT, FLEET STREET, E.C. 4.

GAS METERS
Their Construction, Use, Fixing, Inspection, and Maintenance.
A Handbook for Engineers and Managers, Inspectors, Fitters, and Students.
By A. T. GILBERT,
Late of the Distribution Staff of the South Metropolitan Gas Company and Distribution Superintendent to the Nuneaton Gas Company.
Price 7/6 plus postage, 6d.
WALTER KING, Ltd., "GAS JOURNAL" Offices, 11, Bolt Court, Fleet Street, E.C. 4.

OXIDE OF IRON.
SPENT OXIDE BOUGHT.
BALE & CHURCH, LTD.,
33, ST. MARY AT HILL, LONDON, E.C.3
Phone: Royal 1484.

"TORTO" FIRE CEMENT.
BALE & CHURCH, LTD.,
33, ST. MARY AT HILL, LONDON, E.C.3
Phone: Royal 1484.

"KLEENOFF," THE COOKER CLEANSER
Tins for Sale to Consumers.
In Bulk for Works Use.
(*See "The Gas Salesman," p. 54*).

BALE & CHURCH, LTD.,
33, ST. MARY AT HILL, LONDON, E.C.3
Phone: Royal 1484.

PLANT, &c., FOR SALE & WANTED

GAS PLANT IN STOCK.

PURIFIERS.—Dry lutes, 10 ft. sq and 10 ft. by 8 ft. Also 8 ft. sq. and 10 ft. by 8½ ft.
Condensers.—6 in. and 8 in. Vertical Pipe Condensers. Also Patent Baffle Plate Condensers.
Livesey Washer.—8 in. Connections.
Tower Scrubbers.—5 by 30, 4½ by 36, 4½ by 18, 4 by 12, 3 by 12.
Exhausters.—2000 to 50,000 c.ft. per hour cap.
Station Meters.—4 in., 6 in. and 8 in. Connections. Also 100 lt. and 200 lt.
Station Governors.—4 in., 5 in. and 6 in. Recently overhauled. Cheap for quick sale.
Gasholder and Steel Tank.—10,000 capacity.
Also in stock PUMPS, TANKS, VALVES, CAST-IRON PIPES, TUBING, &c.
Send us your inquiries.
Firth Blakeley, Sons, & Co., Ltd.,
CHURCH-FENTON, *via* LEEDS.

G. R.
FOR SALE BY TENDER.
Closing 1st May, 1925, at 11 a.m.
40 h.p.
GAS PRODUCING PLANT
at
The Government Instructional Factory,
SARISBURY COURT,
near Fareham, Hants.
Forms of Tender can be obtained upon Application to the CONTROLLER OF SUPPLIES, SALES SECTION, H.M. OFFICE OF WORKS, KING CHARLES STREET, LONDON, S.W.

FOR Sale—Four 12 ft. by 10 ft. PuriFIERS, Water Lutes, with 10 in. Weck's Valve and Connections, in good Working Order.
One EXHAUSTER, 10,000 c.ft. per hour, Belt Driven very little used.
Also MOUTHPIECES 22 in. by 15 in. with 6 in. Ascension, Bridge, and Dip Pipes, Hydraulic, Foul Mains, and Valves for four Beds of Eight Retorts and two Beds of Six Retorts.
Apply, the MANAGER, GAS-WORKS, BROMSGROVE.

STEAM-BOILERS For Sale—All Sizes Vertical, Locc-type, Cornish, Portable, and Other Types of Boilers.
Apply
GRANTHAM BOILER & CRANE CO., LTD., GRANTHAM.

250.000 Tons Best Quality YORKSHIRE WASHED GAS NUTS For Sale from 17s. 6d. per ton Pit. DERBYSHIRE GAS NUTS, 1¼ in. by ¾ in., 16s. 6d. per Ton Pit. Delivered prices, any Station, on Application. Small or Large Quantities Supplied.
BUCKLE COLLIERY CO., 121 HALES, CHELTENHAM.

PURIFIERS. — Wanted, at once, a Second-Hand Set of Four DRY LUTE PURIFIERS, complete with Valves, Connections, and Lifting Gear. Size, about 20 feet square by 5 feet deep.
Offers to the MANAGER, GAS-WORKS, HORLEY, SURREY.

CONTRACTS OPEN.

OTLEY GAS COMPANY.
CONTRACT FOR COAL.
THE Directors are prepared to receive TENDERS for 5000 to 7000 Tons of Best Screened GAS COAL or NUTS to be Delivered at Otley over the Twelve Months ending July 31, 1926.
Tenders to be in my hands on or before Friday, May 1, 1925.
A. E. HOLLIDAY,
Manager and Secretary.
Gas-Works,
Otley, Yorkshire.

EDITORIAL NOTES.

Education Scheme Difficulties and Their Treatment.

No innovation such as the Education Scheme for staff members or those training for official appointments in the gas industry can be introduced without some difficulties arising which have to be negotiated. Some time ago we referred to what has been done to correct the original scheme in respect of deficiencies in meeting circumstances which experience had brought to light. The scheme as revised, and as approved by the Council of the Institution of Gas Engineers, the appropriate Government Departments of Great Britain and Ireland, and the City and Guilds of London Institute, has now been incorporated in a pamphlet; and in the current state of conditions, it is, we think, about as perfect as it can be made. The means adopted for overcoming such a difficulty as the want of educational facilities for applying the scheme as originally framed, it is hoped, will prove to be more or less temporary; but meantime we have to get the maximum benefit from the scheme in the ways that are most available. Those who have had this work in hand recognize that it would be most unfair to aspirants for examination and certification honours who, by reason of the disabilities placed upon them by geographical situation and far removal from educational centres where work complying with the scheme is in operation, might be denied facilities for gratifying their legitimate ambition. That there are many such young men in the industry is a matter for congratulation, as it shows the existence of the right spirit, and an appreciation by them of the value of the knowledge and certification for which the scheme provides.

It appears, however, that there are many in the industry, particularly among the juniors, who, after all the explanation that has been given, find it troublesome to understand the details of the scheme, and their own place in it. In view of this, a simple summary has been prepared by Mr. Walter Hole, the Organizing Secretary, in which he has stripped the subject of all technicalities, and has put in plain language an outline of the scheme to serve as a guide to students who have not properly grasped its structural features and intentions. It will be seen from the article (published in later columns) that the scheme now caters for all grades of workers in the industry, from the craftsman up to the man who hopes to gain professional status. The first division deals with the training of gas-fitters; and this has been arranged in conjunction with the City and Guilds of London Institute. We want our gas-fitters to know not only the technics of gas-fitting and the utilization of gas, but also the elements of the sciences upon which those technics are based. Those who go through the course provided and prove in the end that they have absorbed the instruction they have received are the type of men the gas industry needs to-day; and they will be greatly sought after for responsible positions in the important work to be done on the district. Efficiency in gas-fitters means much to the consumers of gas and to the supply undertakings. Then there are those staff men who are engaged in the intermediary work of a gas undertaking—that is the work lying between that of the professional men and the craftsmen. No one who earns his living in the gas industry should be without knowledge of its processes and transactions, so as to be able to talk intelligently on them. There is a regular army of these men in the industry; but a very large proportion are ineffectives so far as the interests of the industry are concerned, other perhaps than in the routine clerical or other work upon which they are engaged from day to day. The inclusion of these in the scheme is a recognition of a latent value to which activity should be given. An increased intimacy with gas-works and gas-supply practices will be an intellectual advantage to them, will safeguard them against a display of ignorance and the pitfalls which surround those without exact knowledge; and, as men employed by a gas undertaking are expected by laymen to be in the position to give them information as to gas applications, their ability to do so will be an advantage to the undertaking. Such men will see from Mr. Hole's article what is provided for them, and how they may proceed. Even those who are isolated geographically, and so cannot attend classes, will find an open door.

Then full information is given in the article as to the professional courses in engineering and gas supply, each of which is divided into three grades—the Ordinary, the Higher, and the Diploma. A list is given of technical institutes where the courses can be taken, and from the Principals of which information can be procured. The list accentuates the fact that there are considerable areas in the country in which there is no proper provision for taking the courses. But these cases have been legislated for in the second part of the scheme, but in a manner which it is hoped will not be permanent in all cases. The necessary information regarding procedure in this connection is given by Mr. Hole towards the end of the article, which he concludes by dealing with the crown of the whole scheme—the Diploma.

A good piece of work has been done in meeting those conditions which opposed—in some respects it is believed only temporarily—the universal application of the scheme; and, after the explanations given elsewhere, the way to achievement should be found much easier by all students and intending candidates for those attestations of competence which will become important aids to securing preferment in the work of the industry.

The Gas Engineer in New Zealand.

THAT the man who undertakes the chief executive and advisory responsibility of a gas-works in New Zealand must be a veritable tower of strength and highly efficient is disclosed by the Presidential Address of Mr. James Lowe, M.Inst.C.E., the Manager and Engineer of the Auckland Gas Company, Ltd., to the Gas Institute of the Dominion. This is a new organization; and there can be no gainsaying that conference between the men of the gas profession in New Zealand is as essential as—perhaps more so than—it is at home or in other countries where organizations have long been established. If, in passing, we regard our conditions at home as the standard for comparison, then we find that, through their geographical situation, the conditions under which gas men in New Zealand have to work and meet difficulties go far beyond it. In contrast, circumstances at home—though we do not consider them light in comparison with the past—are easy;

and we know full well that the more conditions worsen difficulties, the greater the need for courage and technical ability to meet them. Mr. Lowe himself obtained much of his primary professional experience in a school where the gas man had to become thorough, and where he became hardened to difficulties, and met them full face. It was in the early days of this century when we were walking with Mr. Lowe in the gas-works at Glasgow. Thence he went to take the responsibility of the engineership and management at Auckland. He knows the value of professional conference and comradeship; and we wish the new Gas Institute of New Zealand a life of good and helpful work in the interests of the members and of the undertakings they serve.

The word picture which we published last week from the Presidential Address as to the conditions under which the gas industry is carried on in the Dominion, we are confident has given to gas engineers at home interest in their compeers working in the circumstances depicted; and today we reproduce a descriptive account from the same source of the works of the Auckland Company. Though these contain some special features in plant and process which will arrest the attention of gas engineers, we will here confine ourselves to a few comments upon the general conditions which confront the gas engineers of New Zealand, and which they meet with verve and success. It is obvious that there the engineer and manager has to be more self-reliant than the engineer at home. Here there are firms of spacious experience who specialize in various types of plant. Their experience is of inestimable value to the gas engineer, who, however, must have selective capabilities for his particular circumstances and the ability to discriminate and decide wisely on the representations and offers of competing firms. In New Zealand the engineer has to prepare his own plans, and frequently look after the fabrication and, almost invariably, the erection of his own plant. We pride ourselves nowadays in the workshops possessed by our larger gas-works. Mr. Lowe has had the opportunity, through a recent visit home, to make comparison of what is provided here in this respect with what, in the isolated circumstances of New Zealand, has to be furnished there. In consequence of the character of the work that has to be performed, through not being in the position to depend upon contractors for new structure and repairs, he tells us that the workshops on the gas-works in the Dominion have to be equipped with appliances and tools on a scale exceeding that to be found in similar sized works in Britain. One result of the war has been to increase self-reliance by engaging locally in the manufacture of certain forms of gas plant. That is a natural evolution in a distant country such as New Zealand with engineers strong in initiative and execution, and equal to meeting the needs—not only in days, but in years of emergency. There is another incentive to the people of the Dominion to be pioneers to the utmost in providing for their own needs, and that is capital costs, which are, through freightage, insurance, wharfage, &c., some 40 to 50 p.ct. more than at home. This is a further good reason for the exercise of engineering faculties with the view to lower initial costs, so long as efficiency is not assailed.

Again in the distribution department, conditions are not the same as here, though in one respect in this country we are getting a taste, through housing schemes and the construction of fewer houses on a given area of land, of what is a very common condition in New Zealand, save in certain of the principal streets. Mr. Lowe mentions that, owing to the practice of building houses of the detached type on sites usually not less than a quarter of an acre to each house, the density of population is less than in cities and towns at home. This, of course, contributes to higher capital and other costs for distribution, through less services being connected per mile of main with consequent smaller gas consumption per mile, though, naturally, from the health point of view, the open-space system of building has much to commend it. Then the chief meal of the day for all classes is taken in the evening; and therefore in the winter one has the peaks of the lighting, heating, and cookery loads all combining, between five and six o'clock, to make a peak of a formidable order. This also assists to swell the capital expenditure on mains per 1000 c.ft. of gas sold. But by superimposing a high-pressure system on the low-pressure network, considerable economies can be effected in the cost of mains in a growing district.

Considering these matters (and they do not sum up the conditions which, in comparison with this country, are adverse influences), there is no reason to be surprised that gas prices are higher in the Dominion than in Britain. Comparatively, we at home are in a highly favoured position in regard to coal. Unfortunately the most available coals in New Zealand are unsuitable for gas manufacture, owing to sulphur and non-coking characteristics. The result is that Auckland, in common with other gas undertakings, draws coal supplies from the Maitland coal-field of New South Wales, and from the West Coast mines of the South Island of New Zealand. Last year the cost of the coal was £2 2s. 9d., or £1 0s. 5d. more than in 1913; but the price of gas has not risen in the same proportion—being 7s. 6d. per 1000 c.ft., as against 4s. 3d. In this country we think we are badly treated by having to pay an income-tax of 4s. 6d., but in New Zealand it is 5s. 10d., and alone it represents 6·02d. per 1000 c.ft. of gas sold. The narrative of differences which are adverse to gas supply in the Dominion proceeds into unfair competition with Government subsidized electric schemes, towards the provision of money for which the gas undertakings and consumers have unfairly to subscribe as taxpayers. What happens is that the former have to compete with Power Boards supplied with electricity from State hydro-electric works, on which the Government are spending large sums; and are subsidizing them in various ways. The Power Boards do not pay income-tax or local rates, and deficits are made good from the general revenue of the State. We hope things will never go to that length in this country, but we are threatened with the application of part of the same policy. However, in New Zealand Power Boards also receive indirect subsidies through their plant coming in duty free, while gas and steam engines for other people are charged 10 p.ct. duty, and cast-iron pipes above 9-in. diameter and steel pipes above 6-in. diameter pay 20 p.ct. duty. In fairness Mr. Lowe mentions that machinery for any manufacturing purpose is now admitted free of duty, provided it can be shown to the satisfaction of the Minister of Customs that it could not have been economically manufactured in New Zealand. To cap all this, the Dominion possesses the most advanced labour legislation in the world. Agreements can only be made for three years, but invariably the term is two years. Thus labour ebullitions are constantly occurring; and consequently peaceful times for the gas manager are few and of short duration.

While after this gas engineers at home may think a little less hardly of their conditions, they will sympathize freely with their colleagues in New Zealand. It is curious that the Government there should employ their legislative power to pack upon the industrial burdens inseparable from geographical situation, other burdens which are neither just nor contributive to the best public service and interests.

Healthy Buxton.

Those scientists who delight in the measurement of the foreign particles which pollute and densify our atmosphere, and which are so luxuriantly contributed to it by the combustion of raw coal for domestic and industrial purposes in our cities and towns, have on occasion referred to the excellent condition in this respect of the air of Buxton, as compared with that of large industrial centres. But this tribute to the relative purity of the air of the town does not altogether satisfy the Mayor (Alderman C. W. Buckley), whose scientific attainments are well known in the medical world. He can write after his name M.D.(Lond.), and M.R.C.P.; and he is a distinguished consultant on rheumatism, gout, and allied diseases. He is also a University lecturer on balneology, of which subject he is a world-renowned authority. In addition, he is Director of the Biological and Bacteriological Research Laboratories of the Devonshire Hospital, of which he is also honorary physician. We mention these high qualifications to show that his opinions on domestic heating are not without the basis of good authority.

The Buxton Corporation Gas Undertaking (as a report in other columns shows) recently inaugurated new Gas Service Buildings—the title alone discloses their functions,

and attests the existence of a progressive administration. On the occasion, Dr. Buckley spoke of the utilization of gas as a heating agent. He acknowledged how considerably it has developed as a source of heat to the greatest possible benefit of the country, and yet his subsequent remarks indicate how large is the amount of work yet to be done in transferring domestic heating from the smoke-producing methods of our forefathers to the more scientific, cleanly, and labour-saving methods of modern times which have been promoted so extensively by the gas industry. Dr. Buckley is emphatic as to the value of gas as a heating agent. One of his remarks was that he is disposed to say there is no more efficient means of heating than by gas in the present day. It possesses great advantages over coal; and he sees in it the means of helping very largely in the solution of the smoke problem. While admitting that the smoke problem in Buxton is not a serious one, he regards it as quite serious enough; and he asked the people of Buxton to do all they can to eliminate smoke from the atmosphere of the town by using gas for both domestic heating and cooking. He would not have done this did he not believe in the virtues of gas heating. He also accentuated the facts that smoke in the atmosphere does much to prevent people enjoying the full health-giving benefits of sunlight, and that it means a serious waste of the valuable properties of coal. In his opinion, too, the gas fire possesses every advantage which can be claimed by the coal fire; it is not unhealthy, and does not contribute to the deterioration of the atmosphere.

One of Dr. Buckley's remarks suggests a comparison. He was referring to the value that is derived from the carbonizing of coal at the gas-works—mentioning among other points that 10 tons of coal will produce 130,000 c.ft. of gas, in addition to coke, tar, sulphate of ammonia, and the derivatives of tar. The gas supplied in Buxton, we believe, has a calorific value of 510 B.Th.U. per c.ft., so that the 130,000 c.ft. produced from the 10 tons of coal would give a potential thermal value of 66,300,000 B.Th.U. Used in gas-fires, of this quantity some 75 p.ct. would be given to the rooms as useful heat, or 49,725,000 B.Th.U. Some people have the idea that on the basis of heat rendered there is a considerable difference between coal and gas in favour of the former. This notion the gas industry must combat, seeing that the difference resides more in imagination than in actual fact. For instance, assuming the 10 tons of coal were used in domestic fire-grates for room heating, only about 20 p.ct. of the potential heat value of the coal would be given as useful heat; the remainder passing away up the chimney. If the coal has a potential thermal value of 29,000,000 B.Th.U. per ton, the value of the 10 tons would be 290,000,000 B.Th.U.; and 20 p.ct. of this would be 58,000,000 B.Th.U., as against the 49,725,000 B.Th.U. which would be given by the combustion of the gas for the same purpose. Thus we see how narrow becomes the difference; and, from the economy point of view, it is reduced still further by the fact that gas-fires can be lighted and extinguished as needed, while in the case of the coal fire waste of fuel is inevitable through the maintenance of the fire in the time between the stages of actual requirement. Further compensation is given by the labour-saving and convenience of a means of heating which can be used at will; and, moreover, a means which cannot be charged with assisting to produce the miasmic conditions of the atmosphere of which so much complaint is made on account of the injury to health and property. Such testimony as Dr. Buckley gave at the opening of the new Gas Service Buildings for Buxton is invaluable.

The hope of the Mayor that the people of Buxton will turn still more extensively to a fuel supplied to them through pipes and always on tap is likely to be fulfilled, and at a brisker rate than ever before. The new Gas Service Buildings are a means to that end. It is one of the most advanced provisions that has been made for increasing efficiency in the district work of the undertaking; and the district work is the very genesis of gas development. We congratulate the Chairman (Alderman A. W. Wall) and members of the Gas Committee upon their enterprise, and the Engineer and Manager (Mr. F. G. Shaw), whose work for the concern has won for him the complete regard of the Council and of the ratepayers. Another matter for hearty felicitation is the financial condition of the concern. It shows administrative wisdom; and, in these times of high costs, it will be of considerable advantage to the town through the contribution the gas undertaking will make to public service, which should be the predominant feature and aim of any productive concern municipally controlled, and not the making of profits to aid the rates. Many a local authority gas concern may well envy the Buxton undertaking its low balance of unliquidated capital. The capital of £90,000 has been wiped-out with the exception of £7000, and this could have disappeared had not £18,000 been contributed since 1911 to the relief of the rates, and a subscription of £2000 made to the cost of erecting the Town Hall. The expenditure on the new Service Buildings—some £3000—has also been defrayed out of revenue. Happy should be all associated with the Buxton Gas Undertaking.

British Empire Gas Exhibit.

At 10 a.m. on Saturday, May 9, the gates of the British Empire Exhibition will be re-opened to the public. The ceremony is due to begin at 11 a.m.; and the programme is now awaiting the approval of the King. Semi-state, it is expected, will be the order of the day. The arrangements for the Gas Industry's Exhibit are proceeding splendidly. An entirely new show has been devised; and additional adjoining space has been taken. A special feature of the exhibit will be a display, with an Imperial keynote, showing that gas is already freely used, and is fast making headway, for industrial no less than for domestic purposes, not only in Great Britain but throughout the go-ahead Dominions and Colonies. Important industrial uses of gas and coke will be demonstrated on a comprehensive scale, while in the large and artistic Rest Lounge the solution of the housewife's troubles by the use of gas on modern labour-saving lines will be the main attraction. In addition, part of the new space taken will be turned into a hall where demonstrations on the cookery of Empire foods, preceded by short lectures, will be given several times a day.

Coke Competition.

Candidates are reminded that June 30 is the latest date for receiving papers. Full details were published in the "Journal" for Feb. 18. Any additional information required can, by specifically stating its nature, be obtained from the Editor of the "Journal." The prizes range from £200 down to £10—the total sum for distribution (through the kindness of the Woodall-Duckham Company) being £1000. The honour of being the author of a winning paper will also count for much.

Cost of Free Maintenance.

In last week's issue, editorial comment was made upon the statement of Mr. J. W. M'Lusky at the North British Association meeting, as to the cost of free inspection, adjustment, and maintenance of consumers' fittings, less outlay for materials. The figure works out to 0·592d. per 1000 c.ft. sold. From the report of the discussion on the papers by Messrs. Napier and Keillor, and the statement of Mr. M'Lusky (published last week), it is seen that smaller towns are finding that the cost is in close proximity to that of Glasgow. Mr. R. Sturrock, of Ardrossan, states that eighteen months' experience there shows that the cost works out to 0·52d.; and Mr. J. J. Scott, of Cowdenbeath, says in his case—a mining district—the cost does not exceed ¾d. per 1000 c.ft. Mr. M'Lusky also supplied, in replying to the discussion, some further information as to the staff employed on the work, which gives additional value to the particulars as to houses and appliances which appeared in the "Journal" last week.

Blow Gases for Retort Heating.

Mr. James Lowe, the Engineer and Manager of the Auckland (N.Z.) Gas Company, as our readers are well aware, has taken a great interest in the development of water-gas plants. At his works, there are three such plants in continuous use—two of them being installed in conjunction with the horizontal retort-house, and one for the vertical retort installation. An interesting feature is that the blow gases are utilized for heating

the coal-gas retorts. In the case of the plants used with the horizontal settings, the water gas, after being partially cooled, is passed directly into the foul main; but in the third case the hot water gas is passed through the coal charges in the vertical retorts. Thus in both gas processes a higher thermal efficiency is promoted.

Price Increases.

"Meteor" of the "Electrical Times" is cynical regarding the increases of the price of gas which are taking place, owing to the state of the secondary products markets. While this condition obtains in the gas industry, he says reductions in the price of electrical energy are being announced all over the country. Not long since, the electrical papers were crying out against the maintenance of charges for electrical energy which they considered were delaying the arrival of universal domestic electrification. However, "Meteor" says: "It should not matter very much to the gas people that their commodity is growing dearer whilst ours is becoming cheaper; for Mr. Goodenough has recently demonstrated that there is such an enormous gulf between one pennyworth of gas and one pennyworth of electricity that we can only look forward to a continuation of our miserable existence." Mr. Goodenough said nothing about a "miserable existence." What he remarked about the gulf between a pennyworth of gas and a pennyworth of electricity for heating purposes is not altered by the cheap sneers of "Meteor."

Wages Subsidy and Employment.

Various investigations are being made in connection with the proposals that a wages subsidy should be provided in the case of the more important industries to bring about an increase in the amount of available employment. In addition to the Government Committee, who are exploring the whole question of subsidies, and a Sub-Committee appointed by the Executive of the Parliamentary Labour-Socialist party, the Federation of British Industries are also moving in the matter. They have appointed an exceptionally strong Committee to inquire into the proposals for alternative methods of relieving unemployment by devoting moneys at present expended on the dole to the purpose of subsidizing industry and thereby enabling crease in the amount of available employment. In addition to pointment of the Committee, however, is not to be taken as an indication that the Federation endorse the proposal. Indeed, the matter is one of such extreme complexity, and raises issues of such importance, that it is impossible for industry to express any views either one way or the other until the question has been subjected to expert examination, and research made into every aspect. As an outcome of the Committee's labours, the Federation may be in a position to submit recommendations to the Government, always assuming that, after full investigation, industrial opinion is favourable to the scheme.

The Coal Inquiry.

It is difficult to say whether or not any good is likely to come out of the joint inquiry by the representatives of the coal-owners and the Miners' Federation into the conditions of the mining industry with the view of ascertaining what remedies shall be applied. Those upon whose word there could be reliance are not divulging anything; but Mr. A. J. Cook, the Secretary of the Miners' Federation, appears to find it impossible to keep his tongue from wagging, and referring in depreciatory terms to what the Joint Committee are doing. In his opinion the efforts of the Committee represent so much time wasted. He also states that the owners have been pressed for suggestions for improvement, but they have not put any forward. Mr. Cook seems entirely to misunderstand the objects of the exploration that is being made, although he is a member of the Committee. The first thing for the Committee to do is to ascertain and investigate the causes of the present conditions of the industry, and then, when they have done that, to suggest, jointly if possible, the remedies which in their wisdom they consider should be applied. At the same time, Mr. Cook declares that the men are not going to work longer hours, and intend to have a living wage. But if he would sit down quietly for a little time and consider where the money is to come from for an advance of wages for the work performed, he would show a prudence which has been absent from his wild talk—at any rate during the past two or three months. Perhaps if the Joint Committee persevere, they may come to a conclusion which will show how more money can be made, and at the same time increase the demand for British coal in face of foreign competition. Maybe it will be found that the only way of enlarging the revenue from coal is the very one which the Federation and Mr. Cook say they will not tolerate. If it is the only way, and the miners will not apply it, then there is nothing more to be done, but to let things drift on as they are doing now, and so become worse. But Mr. Cook has another plan—the plan of force, which would not provide, but would waste, money. He tells all whom it may concern that the Miners' Federation are going ahead with their arrangements for an alliance with other unions to meet "eventualities." The eventuality he has in mind is no doubt the securing for the miners money which does not exist. Another point is that, although the inquiry is proceeding into the economic conditions of the industry, the various districts are now considering the framing of a new wage programme which is to be discussed at the next delegate conference, when the question of amending or giving notice to end the present wage agreement is to be decided—from the point of view of the miners.

PERSONAL.

Mr. Frank Harding Jones, M.Inst.C.E., who has for many years been a Director of the Wandsworth, Wimbledon, and Epsom District Gas Company, has been elected Chairman of the Company, in succession to his father, the late Mr. H. E. Jones. In making the announcement, the "Wandgas Magazine" adds that "his election secures unbroken the continuity of great and generous services of the Jones family to the Company."

Mr. E. L. Farquhar, of Lower Largo, has resigned the position of Hon. Secretary and Treasurer of the Eastern District of the Scottish Junior Gas Association, and will be succeeded by Mr. John Scobie, of Dunfermline.

The new President of the Chichester Rotary Club is Mr. T. N. Ritson, the Engineer and Manager to the City of Chichester Gas Company. Mr. Ritson, who has taken a great interest in the Rotary movement since the Club was started in 1919, has addressed the members on "Gas and the Bye-Products in relation to the War," and "The Origin and History of Coal;" and he was to have lectured on "Water Supply" last month, but was unfortunately indisposed, so that this had to be postponed.

On the occasion of his marriage, which took place on the 9th inst., Mr. Lawrence Farquhar, Gas Manager at Peebles, was presented by the members of the Town Council and burgh officials with a sum of money with which to purchase a tea service. Provost Davidson, who made the presentation at a meeting of the Gas Commissioners, said Mr. Farquhar had endeared himself to them all by his amiable and quiet ways, and they asked his acceptance of the gift as an expression of their regard.

OBITUARY.

We regret to report the death of Mr. William Bryant, of "Cardynham," Truro. The deceased, whose wife had died only a few weeks previously, had been Chairman of the Padstow Gas Company, Ltd., since its formation, and was a Director of several other gas undertakings in Cornwall, including the Camborne Gas Company. He was a well-known figure in the district, and great sympathy will be felt with his relatives.

Mr. J. Readshaw, who for fifteen years has been one of the London Representatives for the Volker Lighting Corporation, and for Lighting Trades, Ltd., since its formation, died on the 11th inst., at his home at Colliers Wood. The funeral took place on Saturday last in West Norwood Cemetery.

Institution of Lighting Engineers.—In the matter of the payment by local authorities of the expenses of delegates in attending the annual meeting and conference of the Institution in Leeds next September, the Hon. Secretary (Mr. W. J. Liberty) has been officially informed that the Minister of Health "would be prepared to consider applications from local authorities whose accounts are subject to Government audit for sanction to the payment of the expenses of attendance at the meeting and conference of not more than two delegates, one of whom should be the engineer or superintendent for public lighting in the district."

ELECTRICITY SUPPLY MEMORANDA.

Illuminations at Wembley.

Last year there were two sets of opinions regarding the lighting of the British Empire Exhibition grounds. Those who harbour the idea that everything electrical must be good, and who so deceive themselves, considered that the electric lighting was exquisite, and poked fun at the gas lighting in the Amusements Park. But the major electrical opinion was that the gas lighting was excellent, and that electricity had lost one of the finest opportunities it had ever been given to display its capabilities in subscribing to public entertainment by lighting effects. This year in the main parts of the grounds, an attempt is going to be made to do much better in effective illumination. The "Illuminating Engineer" informs its readers that Messrs. Sparks & Partners, the Consulting Engineers, invited the Electric Lamp Manufacturers' Association to put forward proposals; and their Lighting Service Bureau submitted a scheme which has been accepted. But so far as we can gather, there is nothing very original in what is to be done, excepting in respect of a zoological, piscatorial, and horticultural collection of models with (apparently) coloured lamps in their vacuous insides. Some of the principal buildings, entrances, and garden beds will be outlined with electric lamps of selected colours. In the north gardens and at the south-west entrance will be installed two illuminated columns of neon tubes, some 40 ft. high, having the appearance of columns of fire. In "Kingsway," our contemporary says, sixty tall standards are being erected, each fitted with twenty yellow-sprayed 100-watt gasfilled lamps. To provide contrast, and to throw into relief the colonnades of the Palaces of Engineering and Industry, flood-light projectors of a special type will be concealed behind the columns. The lower projectors will be fitted with light blue screens and 1000-watt lamps; the light being thrown upwards. The upper projectors will serve for the downward projection of light of a rose-pink colour. On the roofs steam-jets illuminated by a flood-light projector and colour-screen will resemble dancing coloured flames. The buildings will be outlined with 20-watt yellow-sprayed lamps on 18-in. centres; the panels being treated with green lamps, and the bases of flag-poles with red. There will be the illuminated swans, ducks, Noah's Arks, water lilies, and grotesque fish floating in the lake. Near Digger's Bridge a family of illuminated penguins is being installed; on the lawns and on the southern side of the lake, illuminated frogs, snails, tortoises, rabbits, and hares will be seen. Some of the trees will be alive with flocks of brilliantly lighted and gaily coloured parrots and owls. We are glad they will be of the dumb kind. One spreading oak will be the centre of a miniature "Garden of Eden," and will bear large luminous apples; and entwined round the trunk will be a forbidding serpent studded with green lamps. Oak trees are not supposed to bear the kind of apples of scriptural fame. The trees on the tea or dancing island will be fitted with large oranges and lemons containing 60-watt lamps. The frontage of the Stadium will be flooded with amber light from concealed projectors, and the colonnades will be thrown into relief by concealed lighting of a contrasting colour. On the roof will be a mammoth fan of coloured searchlight beams. We shall be interested to see how it all works out.

Scientific Two-Part Tariffs.

The search for a suitable tariff for the electricity supply industry promises to be an eternal one. The men of the industry have been largely concentrating for some years past on a two-part tariff, but hitherto they have not succeeded in finding one which could glory in the fact that it is founded upon the electrical requirements of the consumers and the electrical costs of meeting their demands. Basing the fixed charge upon rateable value, floor area, or the dimensions of the buttons of the waistcoat of the householder, has no justification, and inflicts upon different individuals divergent treatment which cannot be in any way vindicated. These considerations are well known to the men of the electrical industry; and, to the credit of some of them be it said, they are endeavouring to find means to construct a bi-part tariff which shall have scientific authority. So far, there has not been success. As a matter of fact, the farther they go with their proposals, the more complex the conditions become, and the less explicable to the consumers. It appears that the only possible method to adopt will be to base in some way the fixed charge upon electrical requirements, without taking into consideration the whole of the embroidery which some of the investigators would like to apply to them. These remarks are suggested by perusing two papers which were recently read at a meeting of the Institution of Electrical Engineers. One of them was by Mr. H. M. Savers; and in this he discussed the influences of load factor, diversity factor, and distribution costs and losses upon the construction of a tariff. The other paper was jointly by Mr. G. Wilkinson and Mr. R. M'Court, in which they sought, by "simplification and discrimination," to frame a system which in their opinion could be applied. But the so-called simplification and discrimination there can be no question would lead to still greater confusion in the minds of consumers, and might possibly be obstructive to the greater use of electrical energy which they desire to promote.

Distribution Influences.

The contribution by Mr. Sayers is of extreme interest, as it shows how largely distribution costs should affect the charges to the consumers in particular localities. The author submits that a practical tariff should be based upon costs. This, of course, is a matter of comparative simplicity when applied to factories, traction, and bulk supplies; the only consideration in the upper direction being the cost at which large consumers can generate for themselves, with (say) gas-driven plant. The real difficulty is the case of the domestic consumer. In the domestic business, individual costs of services, meters, and working expenses are relatively high, and dissimilar as between one consumer and another; this being partly due to the differences of their load characteristics. Lighting is at the present time the main demand in electrical domestic service, and the load factor is of the order of 10 to 12 p.ct. If the load factor could be raised from 10 to 30 p.ct., Mr. Sayers says this would reduce the cost of the units sold by at least one-third all round, and probably more. While the influence of load factor on generating costs has been extensively studied, the effect on distributing costs has not been scrutinized so closely. This is no doubt due to the complexity of the subject, and to a disinclination to enter into it in detail. It is pointed out that distribution costs per unit sold are often two to four times the cost of generation. Thus the scope for research into distribution costs is large. An interesting point is made by Mr. Sayers when he says that the diversity factor only improves the load factor on the distribution side if the diverse loads are supplied through the same mains; but the cost of distribution through any one feeder with a 10 p.ct. load factor is not in the least reduced by the existence of other sections enjoying a 50 p.ct. load factor. This is a point which is not always kept in view by electrical men when they are considering somewhat expensive extensions of their distribution systems into rural areas, where the load factor is not likely to be good or the diversity factor of much consequence. In several ways, the author shows that the relations between cost per unit sold, load factor, and form factor, are not alike for generation and distribution; the latter being more complex and more affected by load characteristics. Another useful point to remember is that generation costs when based on "per unit sold" include distribution losses; but, on the other hand, the cost per unit sold, in view of the fact that it includes these losses, is not fair to the station in determining its economy *per se* and the efficiency of its running. In order that means may be taken to reduce distribution costs, one must, of course, obtain information as to their magnitude. This is obvious when one remembers that there are systems where the units sold only reach some 55 to 60 p.ct. of the total sent out.

The Tariff Suggested.

The costs of the units sold through any distributor in a year are: (*a*) The cost of the total number of units delivered to the distributor, including all capital charges and the cost of the losses up to the feeding-point. (*b*) The capital charges to the distributor. (*c*) The capital charges on the services, meters, &c., and the cost of meter-reading, &c., for all consumers. With reference to item "*c*," this should be charged to the individual consumers as a meter-rental, or a charge per KW. of connected load. The total of "*a*" and "*b*" divided by the total units sold gives a sum per unit which, with a reasonable addition for profit, is a proper average price for all the consumers. The method which the author suggests for arriving at tariffs for domestic supply is to classify consumers by their load and diversity factors—that is, by observation of selected groups with similar proportions of connected load for different uses. He holds that tariffs recognizing the load and diversity factors of domestic consumers by classes are practicable, and will attract the most desirable domestic load—thus improving the utilization of distribution systems and bringing about progressively a reduction in the charges to consumers.

A Second Scheme, and a Fine for Excess.

Turning now to the contribution of Messrs. Wilkinson and M'Court, they agree that a two-part tariff is the best for encouraging the greater use of electricity; but they contend that the charge should be based on the electrical requirement of the consumer in watts or kilowatts. Their idea is that the requirements should be classified on a basis upon which the consumer would pay 8d. per KW.H. for a minimum number of units, and a low price per KW.H. for the residue up to a declared maximum. For any excess the user would be fined by charging him at 6d. per unit. Thus we have once more proposed simplification running into complexity. From this state of things our electrical friends seem to find it impossible to escape. It is suggested that for such a tariff a cheap and reliable mechanism is required, which, while limiting the consumer to his declared maximum supply, will also secure a higher rate of tariff during the time when he exceeds, by accident or design, his declared maximum demand. This, we

take it, would mean additional initial costs in fitting out the consumers. The authors believe they have devised a suitable device for the purpose. They use a two-rate meter, on one of the dials of which all current used under normal conditions, including the number of units at 8d. per KW.H., is recorded. After this, the low price per unit comes into operation. Then, if the consumer exceeds his pre-arranged demand, a "discriminator" comes into action, and automatically transfers the record of current consumed to a second dial—the units registered by this being charged at (say) the 6d. rate. We are not surprised that in the discussion there was a good deal of criticism of this proposal. One of the speakers suggested that what was called for was a means not of preventing excess units being consumed, but of preventing their being used when the system is fully loaded. It would, however, be an insuperable difficulty to obtain a mechanism which would discriminate in the case of individual consumers, when using excess units, as to whether or not the system was fully loaded. From the various speakers, the authors did not get much encouragement, though their efforts to design a two-part tariff with scientific authority were looked upon as a good contribution to a vexed question.

"Safety" Items. The electrical papers a time ago hammered at the question of the removal of gas from the service of lighting trains, on the ground that the fires following accidents were due to its presence. Fires were, of course, experienced in train disasters in the days of the old oil-lamp. Our friends were also heedless of the fact that, if a cylinder is fractured containing gas under pressure, the gas does not linger about for the purpose of providing the electrical journals with a point against the rival. The "Lest We Forget" articles of our dear old contemporary the "Electrical Review" are well in memory. We are not going to imitate it, by now pleading that it is time electricity was abolished for use by or on trains because of the fearful results of a collision between two electric trains in the suburb of Las Planas, near Barcelona. Though gas was not used on those trains, the carriages of one caught fire after leaving the rails. What has the "Review" to say to that? The train which left the rails carried about 180 passengers; and the messages from Barcelona state that something like thirty lost their lives, and approximately 105 were injured—fifty, it is feared, fatally. Many of the bodies were terribly mutilated, some were crushed beyond recognition, and others were burned when the train caught fire. We will not ponder over the ghastly details. Will the "Review" in the circumstances? Returning home, we see that the evening services at the Burton-on-Trent churches were brought to an abrupt conclusion on Easter Sunday, owing to a breakdown at the Corporation electricity works. Not only the churches, but other people who had put their faith in the fickle illuminant suffered the penalty of untimely inconvenience. Last Friday week at the Wellington Mills at Port Dundas, Glasgow, there was an explosion of some highly inflammable vapour employed in the waterproofing process carried on at the works. One young woman was killed, and two others were seriously injured. It is conjectured that the ignition of the vapour was caused by a spark from a machine, or by the fusing of an electric light wire. The reporter who made this statement ought to be handed over to be dealt with by the electrical editors in London. There is nothing that makes them so cross and sets them capering so much as the suggestion that electricity is guilty of such conduct.

Water Power and Electricity. During and since the World Power Conference, we have heard a great deal about the cheapness of electricity in countries possessing large water powers; and interesting tales have been told as to the considerable and varied use that is made of the low-priced current. The communities are fortunate in the possession of water power so long as it behaves itself, in view of the fact that countries like Norway, Sweden, and Switzerland are largely dependent upon imported coal. But, as we pointed out some time since, those countries with their water-power generated electricity have their difficulties, and occasions when supply cannot possibly satisfy the demand. There come periods of drought when there is incapacity to meet the large loads put upon the plant at times of luxuriant provision by Nature of water power. We find from a report published in London as recently as April 6 that in Switzerland, in certain districts and in many towns, electricity is still being rationed owing to the continuation of drought all over the country. It is a pity we cannot transfer some of our superfluous rainy weather to the drought-oppressed people of Switzerland. For some six months they have had a drought; and it is causing all sorts of difficulties through the country—among them being this one of the provision of electricity. The only means for avoiding insufficiency of water power during periods of drought for the supply of electricity is to provide large steam-raising plants as standbys to the water power; and the larger the use made of the water-power generated current, the greater must be the aggregate of the steam-raising units. This means a considerable expenditure of capital, which must be a charge at all times upon the consumers of the water-power generated electricity.

LOW-TEMPERATURE DISTILLATION.*

"Low-Temperature Distillation," by Sydney H. North (late Editor-in-Chief, "Oil Engineering and Finance") and J. B. Garbe (late Assistant Professor at the University of Louvain), is, above all, well written. When the authors deal with what may be termed the "straight" technical matter, they are sound enough; but when they beat the big drum of low-temperature carbonization—and this is done at intervals far too frequent throughout the book—they are too sweeping in their conclusions, and too apt to be carried away by their own viewpoint. No thinking man will deny the desirability of obtaining a home-produced oil supply; and if this can be done by distilling what is now regarded as waste fuel, a great industrial need will be filled. But when the authors go on to say glibly that, "for ordinary industrial fuel . . . and for domestic purposes of every form, the future lies in passing all the bituminous coal through low-temperature carbonization, extracting the maximum of oil possible of the highest quality, and forming ultimately a synthetic coal, smokeless and adapted in composition and form to the purpose for which it is destined," the man with a broad scientific outlook will not be greatly impressed by this dogmatic statement and many other similar ones; nor will he agree that "the experimental period of low-temperature treatment is past."

The first chapter takes the form of an introduction to the subject; and the authors say that the great mistake which has been made by the majority of those who have turned their attention to the invention of a process whereby the bye-products from coal could be obtained has been that they have set out with the idea of securing as great a variety of products from the coal as possible, instead of directing their energies into one definite line. The object which should be kept right in the forefront, they state, is that of producing the largest quantity of oil, and using whatever residual fuel is obtained for briquette manufacture, combining this with waste bituminous coal. The next chapter is devoted to early experiments in the destructive distillation of coal; and it is put forward that "in carbonizing coal for gas-making purposes and in heating it for the production of coke, what are to-day very valuable products are lost." We would remark here that, if in exchange for a shilling piece twelve coppers were received, the shilling would not be lost; and the mere fact that the authors of "Low-Temperature Distillation" prefer their shilling to be replaced by a sixpence and two coppers is no argument in favour of their plan. According to Messrs. North & Garbe, carbonization of coal is carried out for two chief purposes—one for the manufacture of illuminating or power gas, the other for the production of coke. "Illuminating gas," in view of the enormous and ever-extending use of gas for heating, is to-day a meaningless term.

Three chapters are devoted to descriptions of modern low-temperature plant and special points in modern practice; and others deal with the subjects of peat, lignite, oil shales, briquetting plant, treatment of the residue from distillation, and the materials available in Great Britain. Throughout the book considerable importance is attached to the need for carbonizing at really low temperatures, and stress is laid on the utilization of superheated steam as a distilling medium. In discussing the experiments which have been carried out by the Fuel Research Board, the authors suggest that the temperatures generally employed at the Board's station are not those from which the best results, as far as quantity and quality of the oil are concerned, may be obtained. Speaking of the tests made in connection with a South Wales gas coal, they say that "admirably as the work was done, and interesting as are the results, they do not add anything to our previous knowledge. The temperature employed was so high that the principal product was gas, with the result that the yield of oil was small. . . . It is curious that the Board, in view of the great need of this country for an oil supply, do not devote some attention to the temperatures at which this could be secured."

"Low-Temperature Distillation" is—as we have already mentioned—exceedingly well written; and it will be read with interest, profit, and enjoyment. If all do not fall in line with the opinions it expresses, at least it does put forward opinions—and this in itself is of the utmost value. An appendix to the book, in addition to a consideration of the production of oil from coal, anthracite, lignite, peat, &c., by "hydrogenation," contains many useful tables and results of tests.

* "Low-Temperature Distillation," by S. H. North and J. B. Garbe. Sir Isaac Pitman & Sons, Ltd. Price 15s. net.

Gas in Dental Surgeries and Clinics.—The current issue (No. 133) of "A Thousand-and-One Uses for Gas" shows the important part which heat plays in the various processes involved in the manufacture of dentures. It gives an interesting "peep behind the scenes" into the dental mechanics' workshop, and proves that, in almost every stage of the modelling and finishing of dentures, gas is required. The issue, with its numerous excellent illustrations, will be of interest to dental surgeons and others professionally engaged in this work.

ELECTRICITY SUBSIDIZING.

The Case of Great Yarmouth.

The idea that the Unemployment Grants Committee will, to help to relieve the workless, subsidize electrical schemes, no matter their nature, by paying over a long term of years 50 per cent. of the interest on the money expended, has tempted many electrical engineers to evolve projects and estimates. Some of these are vague, inconclusive, and absurd; and we think there will be a good deal of disillusionment and disappointment before the end is reached. If we are wrong in this, and those who have to deal with such schemes on behalf of the Government allow conditions such as have been assumed, for example, in the case of Great Yarmouth by the Corporation Electrical Engineer (Mr. P. G. Campling), in making estimates for a scheme involving an expenditure of close upon £200,000, then there would be good cause for a general revolt against this sort of thing on the part of the taxpayers, and especially those large ones who are in business competition with electricity supply concerns. It is not the duty of the Government to render financial aid to one industry to the detriment of another engaged in equally important public service.

In this article we intend to examine the estimates for the Great Yarmouth project; and we should like an answer to two questions: Have the Electricity Commissioners approved of the Great Yarmouth scheme? If so, have they agreed to the terms adopted by the Electrical Engineer for the repayment of the loans required for carrying-out the scheme—terms of years in some cases which are opposed to the practice of the Commissioners? We should not be surprised to learn that they have approved of the scheme from the technical point of view; we should be astonished to find that they have granted the whole of the periods of repayment upon which Mr. Campling has budgeted, and upon which periods the whole financial structure and outcome of the scheme rests. Then, assuming the Electricity Commissioners have concurred in the repayment periods (to which further attention will be directed presently), will the Unemployment Grants Committee pledge the Government to pay for fifteen years half of the interest involved by the proposed outlay, some of which it is intended to spread over the next three or four years?

Opportunism—Relation of the Scheme to Unemployment.

Before dealing with the financial aspects, there are one or two general observations we should like to make. Unemployment grants, we were under the impression, were intended for the specific purpose of giving work to the unemployed; but in this £200,000 scheme for Great Yarmouth, the specific purpose of the expenditure is not for the relief of unemployment, but to bring an effete electricity supply system up to approved modern standards. Such expenditure is entirely a matter for the undertaking itself; but the report of the Electrical Engineer, with its assumptions as to long-period repayments and a generously-disposed Government in the matter of grants, distinctly discloses an idea that the opportunity is a good one for setting the Great Yarmouth electrical house and system in order by the useful aid of national funds. It is clear that those who are looking after the electricity supply of Great Yarmouth are opportunists of the first water. But is this fair to other industries who are large taxpayers, and especially to the industry with which electricity is in keen competition?

There is another general point. It is that, as already said, the unemployment grants or subsidies were intended to assist employment in industries which are suffering seriously from lack of work; but we are not aware that this is the state of things in the electricity industry, or the part of it supplying plant. Thus any money the nation has to spare for subsidizing work should be directed to the most needy quarters. The heaviest part of this Great Yarmouth scheme proposes that the entire transmission, transforming, and distribution system should be converted to three-phase 50 cycle, which necessitates also rewinding and wiring motors, and changing meters and lamps, and involves an expenditure of £130,679, out of the total proposed outlay of £194,476. The whole of this work, it seems, would have to be done anyway to modernize the system, and fit it for the work it has to do; and therefore the scheme would have to be carried out whether or not subsidies are allowed. We cannot see the slightest justification for the Unemployment Grants Committee allowing any subsidy in the way of interest for any term or terms of years for any part of this work; if an exception is made for a single part, it should be restricted to the cost of the unskilled labour employed in the laying of the cables.

The Scheme.

To enable readers properly to appreciate the position, it should be mentioned that the present supply of electricity in Yarmouth is of the earliest character known as the single-phase system; and the Electricity Commissioners have refused to sanction further loans for extensions to this obsolete system. The Corporation have therefore resolved to change it from single phase to three-phase alternating current. Hence the report of the Electrical Engineer, recommending a scheme (including a new generator, converter, and boiler plant), and involving a total estimated cost of £194,476. The Electricity Committee and the Council have accepted the report; and there seems to be an understanding among the members of the latter that the Electricity Commissioners have also approved the scheme. From an engineering and technical point of view, that may be so; but we cannot think the Commissioners have had before them the financial side of the proposals as submitted by the Electrical Engineer, or, if they have, we cannot believe they have given their approval to it.

Uncertain, but Worth the Attempt.

Dealing with the financial weaknesses of the scheme, we cannot do better than begin by quoting the following passages from the report of the Electrical Engineer:

> From information obtained, the Unemployment Grants Committee are likely to assist in this scheme to the extent of 50 p.ct. of the interest for a period of fifteen years, *in view of which I should attempt to get sanction for the whole scheme.*

> By adopting the entire scheme, you are making provision for the future, modernizing your power station and distribution systems, by which increased revenue may be earned, and the outlay will effect savings equivalent to £12,500 per annum. Against this we have . . . estimated loan charges which show that it is possible to do all this modernizing and be approximately £2000 to the good.

There are two or three striking points about the foregoing extract. The first is the uncertainty as to what the Unemployment Grants Committee will do. They "are *likely* to assist in this scheme to the extent of 50 p.ct. of the interest for a period of fifteen years." A more likely thing is that they will not do anything of the kind when they learn of the opportunism underlying this project, as revealed by the naive statement: "In view of which [that is, what the Grants Committee are 'likely' to do] I should *attempt* to get sanction for the whole scheme." The suggestion of an "attempt" indicates an uncertainty in the mind of Mr. Campling as to whether there will be success in this. The "likely" assistance shows the frailty of the foundation upon which the financial structure of the scheme (as given in the report) rests—a scheme which, in every particular, should have its costs charged against the undertaking itself, and not be subsidized from any external source. We are afraid that—deducting the hoped-for savings from the charges based upon long repayment periods and the scooping-in from national funds of 50 p.ct. of the interest for fifteen years—the "£2000 to the good" is an aspiration for the fulfilment of which the chances are very slight. The Electrical Engineer finds the scheme will effect savings of £12,500, and the total of the interest and sinking fund charges will be £15,408, showing an annual deficit on the working of £2908. But if the Unemployment Grants Committee allows a grant of 50 p.ct. of the interest (which amounts to £9679), this would give £4840, from which the deficit of £2908 could be deducted—thus showing a profit per annum of £1932, or (say) £2000. That is really humorous. We were unaware that the Unemployment Grants Committee were appointed to help to put profits into the pockets of electricity undertakings. Of course, the estimated advantage all depends on the repayment periods allocated to the loans by the sanguine Electrical Engineer and the generosity of the Grants Committee.

Loan Periods.

Next let us consider the loan periods—optimistically hoped-for and probable! The Electrical Engineer of Great Yarmouth has a good opinion of plant longevity, and of the "capital" value of replacements of appliances in the possession of consumers. There is little doubt he has gone far beyond what is probable in this matter. For a new steam pipe system, he has assumed a 25-year repayment period; 15 to 20 years is likely to represent the maximum allowed by the Electricity Commissioners. While he takes 30 years for a water-circulating system, the maximum usually allowed by the Commissioners is 15 to 20 years. The estimate of 15 years for a generator and 20 years for a converter will no doubt be realized. But 25 years for boiler plant may have a maximum of 20 years applied to it. The Electrical Engineer is probably right with 25 years in respect of cabling and sub-stations; but to take 25 years for rewinding and wiring motors and changing meters and lamps is absurd. The maximum is 3 to 5 years. These three items—rewinding motors and changing meters and lamps—it is calculated, will represent an outlay of £23,104. This amount of expenditure is merely to substitute something at present existing, and is to all intents and purposes a gift to the consumers; there is no capital value represented by the outlay either to the undertaking or the consumers. Therefore, is it likely the Electricity Commissioners will allow a repayment period of 25 years for these items? Is there any definite knowledge that maxima repayment periods based upon precedents will be allowed by the Commissioners in respect of all the other items of expenditure? About the Engineer's estimates, indefiniteness is, in our opinion, a prominent feature. His computed profit, too (which has no doubt caused some of the councillors to thank heaven for a highly considerate Government with a charming preference for things electrical), is further built on the mere hypothesis that the Unemployment Grants Committee will make a

grant of 50 p.ct. of the interest for fifteen years. As already indicated, we fail to see how the Committee can make a grant of interest on capital for such things as changing consumers' meters and lamps and rewinding motors.

Supposing There is No Grant.

There is thus something beautifully problematical about the repayment periods and the extent of the grant of interest. However, for the sake of argument, allowing for a grant of 50 p.ct. of interest in all cases, and adjusting loans to the maximum periods, we find that a total of £14,613 would be required to meet loan charges and interest. Deducting from this the estimated savings of £12,500, instead of a profit of £2000, we arrive at a deficit of £2113. Supposing the grant of £4840 towards interest is not obtained, the annual total required to meet loan charges and interest would be £19,453, which would leave a deficit of £6953, or roundly £7000, as compared with the Engineer's estimated profit of £1932. We cannot think that the Unemployment Grants Committee have led the Corporation to believe that a grant of 50 p.ct. of the interest will be allowed for a period of fifteen years on the total expenditure of nearly £200,000. Nor can we imagine that the Electricity Commissioners will sanction loans for periods of 25 years for rewinding motors and changing meters and lamps. If assurances of the kind have been given, then it is time such unsound finance and preferential treatment of an industry was exposed by every available means, and the strongest possible protest made in the proper quarters by those adversely affected. Among those adversely affected are the taxpaying gas undertakings of the country and their customers. However, if the authorities do their duty, the financial estimates of the Electrical Engineer of Great Yarmouth will undergo considerable modification before the scheme he has drawn up issues from their hands.

THE INSTITUTION OF GAS ENGINEERS.

Council Meeting.

A meeting of the Council was held at No. 28, Grosvenor Gardens, Westminster, on Monday, April 6; the chair being taken by Mr Charles F. Botley, Senior Vice-President, owing to the absence through indisposition of the President, Mr. J. Ferguson Bell.

There were also present Mr. John Wilkinson, O.B.E. (Vice-President); Messrs. James E. Blundell, J. Wesley Whimster, John M. Campbell, John W. M'Lusky, Charles S. Shapley, C. Dru Drury, and John Terrace (ordinary members of the Council); Messrs. Edward F. Keable (Eastern Counties Association), Harold Davies (Manchester District Institution), James Campbell (North British Association), and Leonard J. Langford (Southern Association); Messrs. Samuel Tagg, J.P., and Thomas Hardie (Past-Presidents); and Mr. W. E. Price (Hon. Secretary).

In opening the proceedings, the Chairman made a feeling reference to the death of Mr. Harry E. Jones, Past-President, and Mr. A. F. Brown, member of the Institution, which had occurred since the last meeting; and the Council's sympathy was suitably expressed.

A message to H.R.H. the Prince of Wales, on his departure for West Africa, was reported, together with the reply to it which had been received from the Prince.

It was resolved to recommend to the members at the forthcoming annual meeting that the sum of £100 be voted to the fund for establishing a memorial to the late Lord Moulton, Past-President of the Institution. Its object is to obtain the sum of £3500 for the conversion of the schoolroom at Kingswood School, Bath, in which Lord Moulton spent so much of his time when a schoolboy, into a memorial hall.

The following candidates were approved for the ballot-list to be issued in connection with the annual general meeting:

For the Class of Member—Messrs. G. E. Anderson, Newcastle-on-Tyne; R. L. Atkinson, Newcastle-on-Tyne; C. Breaks, Ellesmere Port; H. W. Dean, Padiham; John Domain, Ripon; J. E. Dixon, Newcastle-on-Tyne; G. W. Perks, Stockton-on-Tees; and N. Reid, Redheugh.

For the Class of Associate Member—Messrs. A. P. Alexander, South Bank; W. Bell, Reading; F. J. Bengough, Birmingham; E. Birch, Stockton-on-Tees; J. R. Cleator, South Bank; H. E. Cowles, Nechells; W. C. Kimpster, Newcastle-on-Tyne; T. R. Mortimer, Brighouse; and F. Nicholls, Gateshead-on-Tyne.

For the Class of Associate—Messrs. H. P. Clark and F. S. Townend, of London.

The following associate members were approved for transference to the class of member: Messrs. H. Curtis, Macclesfield; D. Muir, Pontypridd; and George Walmsley, Londonderry.

The nomination of officers and ordinary members of Council, for election at the annual meeting, was proceeded with; and it was resolved unanimously that the following be nominated:

President—Mr. Charles F. Botley, Hastings.

Vice-President—Mr. H. D. Madden, Cardiff; the Vice-President remaining in office being Mr. John Wilkinson, Nottingham.

Hon. Secretary—Mr. W. E. Price.

Auditors—Mr. S. Y. Shoubridge and Messrs. Wood, Drew, & Co.

Ordinary Members of Council—Messrs. J. H. Canning, O.B.E., Newport, and Harold E. Copp, Hull.

Members nominated in pursuance of article 40 as ordinary members of Council were reported as follows: Messrs. C. R. Armitage, London; W. H. Bennett, Redhill; George S. Frith, J.P., Runcorn; Leonard J. Langford, Tunbridge Wells; Samuel Shadbolt, South Bank; and Charles H. Webb, M.Sc., Stourbridge.

It was resolved that the London Gold Medal relating to papers read last year should be awarded to Mr. R. E. Gibson, for his paper on "The Construction of New Coal-Gas Works at Garston."

It was reported that the late Mr. Harry E. Jones, the donor of the London Gold Medal, just previously to his lamented death, had transferred to the Institution stock of the Uxbridge, Maidenhead, Wycombe, and District Gas Company, the interest of which would provide for the future award of this medal year by year. The thanks of the Council were expressed, and it was agreed that permission be sought for the medal to be known in future as the "Harry E. Jones London Medal."

The interim report of the Wrought-Iron Tubing Inquiry Committee was presented; and it was reported that the metallurgist appointed to draw-up a specification had just delivered it. This was referred to the Committee for consideration.

The Joint Committee on the Standardization of Gas Flanges presented their report, in which it was stated that agreement had been arrived at between the Committee and the British Engineering Standards Association. Particulars of the standard flanges would shortly be published.

A conference was reported, at which the Institution was represented by Mr. F. W. Goodenough and the Secretary, which had been organized by the Association of Teachers in Technical Institutions on the subject of the "Relationship of Technical Education to other forms of Education and to Industry." An invitation for the appointment of two representatives of the Institution to assist further in this matter was accepted; and it was resolved that their appointment be left with the Advisory Committee on Education.

It was reported that the Transactions of the First World Power Conference had been obtained for the Library for reference purposes; it being recognized that their contents would be of great value to the Institution.

In response to a request of the Non-Ferrous Research Association, it was agreed that the sum of £10 10s. be subscribed in aid of their funds.

Arrangements for the ensuing meeting of the Gas Investigation Committee were considered; and the suggestion that it be held at Leeds on Thursday, May 21, was approved. This arrangement would enable the Committee to inspect the Corbet-Woodall test plant in operation.

It was resolved that the Institution of Gas Engineers should become an affiliated member of the Smoke Abatement League of Great Britain, and that the President and the Senior Vice-President be appointed delegates.

An invitation from the Royal Sanitary Institute for the Institution to appoint two delegates to attend their Congress at Edinburgh from July 20 to 25 was accepted, and Mr. John W. M'Lusky, Glasgow, and Mr. James Campbell, Dunfermline, were appointed to attend.

The details of the arrangements for the forthcoming annual general meeting were considered, including the organizing of the various visits on Thursday afternoon, June 11, and to Derby on the following day.

Blinded Soldiers as Telephone Operators.

It may not be generally known that one of the most successful occupations taught to the blinded soldiers at St. Dunstan's is telephone operating. A large number of these men have found employment with important business firms and organizations in London and the Provinces; and not a few employers state that their boards have never been so well and efficiently managed as by their blinded soldier operator. This may be because the freedom from outward distraction—a natural accompaniment of blindness—enables the blind operator to concentrate on his work to a much higher degree than is possible for a sighted operator, and thus he can maintain an excellent service. St. Dunstan's have several fully-trained men ready for work. There may be some readers faced with a necessary change in their present arrangements who might like to give a St. Dunstan's operator a trial. If so, the authorities at St. Dunstan's Headquarters (Inner Circle, Regent's Park, London, N.W. 1) will gladly supply full particulars. A point to bear in mind is that the employer's liability for his blinded soldier operator is no more than for an ordinary employee. To his employer he is a perfectly normal member of the staff. His special needs as a blinded ex-Service man are the permanent and sole responsibility of St. Dunstan's After-Care Organization.

THE JAPANESE EARTHQUAKE OF 1923.

Effects on the Tokio Gas Company.

Tokio suffered severely in the great earthquake which caused so great a loss of life and property in Japan during September, 1923, and of this a full share, of course, fell to the lot of the Tokio Gas Company, who, however, struggled with their difficulties in a manner deserving of the fullest possible praise.

Sunamachi Works.

Fukagawa Works.

Fukagawa Works.

GENERAL VIEWS OF THE CONDITION OF THE WORKS AFTER THE EARTHQUAKE.

An idea of the effect of the earthquake on the Company's works and property generally will be gathered from the accompanying series of photographs, for which we are indebted to Mr. K. Sato, who has recently been visiting this country investigating modern methods of gas manufacture, in order to arrive at some definite conclusion as to the types of plant which, in the circumstances, it is preferable for the Company to adopt.

The total capacity of the plants of the Tokio Gas Company—who have five manufacturing stations and two bye-products works—may be placed at about 25 million c.ft. of gas a day, for the supply of the city and suburbs, and the mileage of mains at some 1670. Much damage was done to the 3 million c.ft. per day Koppers coke oven plant at the Omori Works, and to the 2 million c.ft. per day vertical retort installation at the Shiba Works. Damage to a more or less serious extent was also caused to the horizontal, inclined, and vertical retort installations in three other works.

Effect on the Holders.

One of the strangest effects of the earthquake, so far as the gas-works was concerned, was in connection with the holders. Friction resulting from the earth movements caused the emission of weird sounds, and water was discharged in huge quantities. The sight was a terrible one, but closer investigation revealed the comforting fact that the damage was less extensive than at first appeared probable. Particularly in the case of the larger holders, having a capacity of (say) over 1½ million c.ft., the actual damage was really trifling—only the guide-rollers being thrown out of gear. From this experience it may be

How Coal-Feeding Hopper was Broken Down.
Of the 72 cast-iron hoppers, no fewer than 30 were broken.

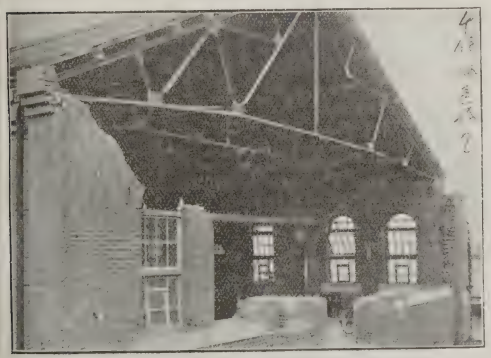
These ovens had a daily capacity of 3 million c.ft.



SPECIMEN PHOTOGRAPHS OF BUILDING WRECKAGE.

concluded that the construction of a gasholder is sufficiently elastic to enable it to withstand even such a shock as results from a very big earthquake.

Generally speaking, the foundations of the machinery and plant were but little affected; and this applies particularly to the foundations of the settings and gasholders. Therefore the damage to the settings already referred to may be assumed to have been due to oscillation of the structure, and not to the giving way of the foundations themselves.

Of the other plant, that most seriously damaged was a purifying box at the Omori Works, 35 ft. by 120 ft. by 6 ft., made of cast iron and supported by reinforced concrete pillars. The damage to the mains consisted principally of loosened and drawn joints; and the Company have therefore deemed it wise to make careful investigation with a view to ascertaining what may be the most suitable form of joint for future use.

Gas Supply Ceases.

Immediately following upon the earthquake, fire broke out, and from this cause the gas supply was stopped. The most serious damage sustained by fire was, however, in connection with the bye-product plant at the Saruye Works. The holders within the area which was affected by the conflagration remained unaffected—indeed, by acting as a screen, they exercised a restraining influence upon the progress of the flames.

At first it was uncertain how long the gas supply would have to be discontinued, owing to the serious destruction caused by both earthquake and fire; but within three weeks of the disaster, the Company were able to restore the supply to a small district in the city, and within two months the whole of the area was again receiving gas. This indicates the great energy and enterprise displayed by the engineers of the Company in this devastating emergency. The work naturally had to proceed uninterruptedly day and night. It was of a very strenuous character; and, of course, what was then done was of a temporary nature.

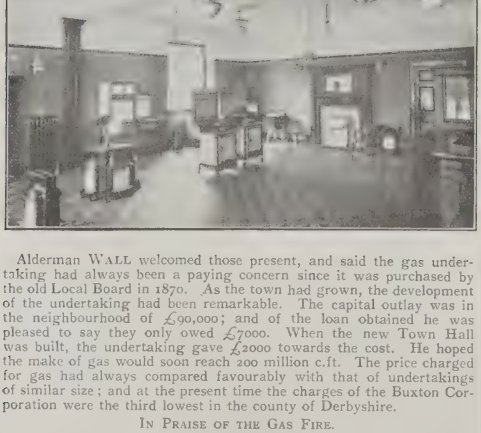
Extensions Contemplated.

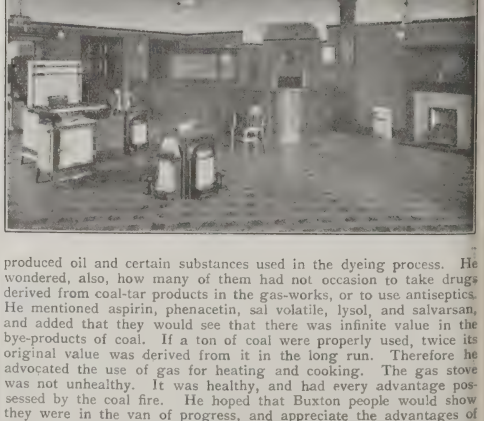
The demand for gas by the citizens is continually growing, and to meet this a scheme has been prepared to extend the capacity from the present 25 million c.ft. daily to some 75 millions.

GAS SERVICE BUILDINGS AT BUXTON.

Official Opening.

New Gas Service Buildings on Eagle Parade, Buxton, were officially opened on Wednesday, April 8, by the Mayor (Alderman C. W. Buckley, J.P., M.D., London, M.R.C.P.), who was accompanied by the Mayoress. There were also present a number of members of the Council, officials, and others—including Alderman A. W. Wall (the Chairman of the Gas and Water Committee of the Buxton Corporation) and Mr. F. G. Shaw (the Gas Engineer and Manager). In the course of the proceedings some remarks on gas heating were made by the Mayor, to whose views on the subject great weight attaches by reason of the fact that he is a distinguished consultant on rheumatism, gout, and allied diseases, University Lecturer on Balneology (on which he is a world-renowned authority), and a Director of the Biological and Bacteriological Research Laboratories of the Devonshire Hospital, of which he is also Honorary Physician.





Alderman Wall welcomed those present, and said the gas undertaking had always been a paying concern since it was purchased by the old Local Board in 1870. As the town had grown, the development of the undertaking had been remarkable. The capital outlay was in the neighbourhood of £90,000; and of the loan obtained he was pleased to say they only owed £7000. When the new Town Hall was built, the undertaking gave £2000 towards the cost. He hoped the make of gas would soon reach 200 million c.ft. The price charged for gas had always compared favourably with that of undertakings of similar size; and at the present time the charges of the Buxton Corporation were the third lowest in the county of Derbyshire.

In Praise of the Gas Fire.

The Mayor (having unlocked the door of the new showroom) expressed his pleasure at performing the opening ceremony in connection with this new venture of one of the most profitable undertakings of the town. Gas, owing to the enterprise which had always marked the undertakings of the country, had developed into a science of heating to an extent which had been of the greatest possible benefit to the country. He was disposed to say that there was no more efficient method of heating in the present day than by gas. He indicated the advantages in the household of gas over coal, and said that gas would help to dispose of the smoke problem. The smoke problem in Buxton was not so serious as in some towns; but it was quite serious enough. They knew of what value sunlight was to the nation and the individual, especially the children. Therefore he wanted them to do all they could to eliminate smoke from the atmosphere; and the method ready to hand was the use of gas for domestic heating and cooking. The Corporation realized that the first step towards the solving of the smoke problem was to put their own house in order. They had done this, and now it was their duty to point out that black smoke could be avoided by the use of gas for heating or coke for furnace purposes. Black smoke also meant a serious waste of fuel. Ten tons of coal purchased at about 35s. per ton would produce more than 130,000 c.ft. of gas, which meant, at the present price of gas, that the gas produced would be of greater value than the coal placed in the retorts. In addition, 10 tons of coal produced 7 tons of coke, 175 gallons of ammoniacal liquor, and 100 gallons of tar, which in turn produced oil and certain substances used in the dyeing process. He wondered, also, how many of them had not occasion to take drugs derived from coal-tar products in the gas-works, or to use antiseptics. He mentioned aspirin, phenacetin, sal volatile, lysol, and salvarsan, and added that they would see that there was infinite value in the bye-products of coal. If a ton of coal were properly used, twice its original value was derived from it in the long run. Therefore he advocated the use of gas for heating and cooking. The gas stove was not unhealthy. It was healthy, and had every advantage possessed by the coal fire. He hoped that Buxton people would show they were in the van of progress, and appreciate the advantages of gas by extending its use in their households.

Alderman Clark, J.P. (the Chairman of the Chesterfield Gas Committee), congratulated the Buxton Gas and Water Committee, and said the management of the Gas Department was efficient.

Mr. J. Mason Frith, J.P. (the Chairman of the Runcorn Gas Company), also congratulated the Committee on the fitting-up of so fine a building for the purposes of gas service.

The Mayor, Alderman Clark, and Mr. Mason Frith were thanked for their remarks; and silver salvers were presented to the Mayor and Alderman Wall by Mr. Shaw, who thanked the Corporation for the way in which they had supported him. The Mayoress was presented with a handsome bouquet by Mrs. Shaw.

The company afterwards inspected the buildings, and subsequently took tea at the Eagle Hotel.

Coping with Growing Demands.

Modern conditions and the ever-increasing use of labour-saving gas appliances have called for improved methods of catering for the consumers; and with the expansion of Buxton new premises for the distribution department have been urgently needed for many years. Soon after his appointment in 1911, Mr. Shaw reported on the matter, and the old gas showroom was opened in 1914—the war preventing developments then in contemplation. Soon after the end of the war the matter was frequently before the Gas Committee; and after many schemes had been considered, a portion of the Old Devonshire Hotel was acquired. The site presented many advantages. It enabled the workshops, offices, stores, and showrooms to be concentrated in one building, with proper supervision and control, and provided a good display site near the Town Hall. The workshops are reasonably isolated from surrounding property. A further valuable portion of the scheme is the provision of three workmen's flats on the second floor; and these are occupied by employees of the department, who are at constant call at night for urgent repairs and other emergencies.

The whole of the work of reconstruction has been carried out by the Gas Engineer and his staff, with the aid of local contractors, and has been paid for out of revenue.

New Showrooms, Offices, and Workshops.

Before the move to the new offices, the staff was split-up. The fact of having all the departments under one roof will make both for economy and efficiency; and, what is even more important, the fine showroom and demonstration room will materially assist the department in their progressive sales policy. The appointments of the ground floor showroom and office are in oak. To the right upon entering is a semi-circular counter and the office accommodation for the clerks. From the showroom, a staircase leads to a small waiting room and the demonstration room, in which are many gas appliances in full working order.

The portions of the building already referred to are those which will be seen by the public. Returning to the ground floor, a long corridor leads to the back of the building—workshops and stores being situated on either side. The stores are also on this floor.

On the first floor, behind the demonstration room, are the Gas Manager's office and other offices, the public lighting department and street lamp store, stock rooms, the official gas testing station, &c.

INSTITUTION OF GAS ENGINEERS.

EDUCATION SCHEME.

By Walter Hole, Organizing Secretary.

Now that the revision of the scheme is completed, it is thought that a brief description, setting forth the whole of the arrangements in the simplest possible language, may be acceptable to those for whom the scheme is intended.

The junior educational work of the Institution is now grouped in three main divisions—viz.:

I. Craftsman's division, dealing with gasfitting.
II. Intermediate division.
III. Professional division.

I. Gasfitting Course.

The first division deals with the training of gasfitters as craftsmen, and is arranged in conjunction with the City and Guilds of London Institute. The course for this subject, which is open to lads of 16 years of age and upwards, runs for five years. Instruction is given not only in the technics of gasfitting and the utilization of gas, but also in the elements of the sciences upon which those technics are based. The examinations consist of written, practical, and *viva voce* tests. The certificates gained in the final year of the course will be endorsed by the Institution of Gas Engineers, and will therefore be a very valuable possession of the successful candidate. Full particulars of the regulations, syllabuses, and centres of instruction may be obtained from Mr. C. C. Hawkins, Superintendent, Department of Technology, City and Guilds of London Institute, No. 29, Roland Gardens, Old Brompton Road, London, S.W. 7.

II. Minor Grouped Courses in Gas Engineering and Gas Supply.

There are many men in the industry, alike on the works, on the district, and in the office, who cannot see their way, or have no desire, to qualify for professional status on the commercial or engineering sides of the industry, but who are desirous of learning more of the processes and transactions of the industry in which they are daily engaged. For these, Minor Grouped Courses have been arranged in conjunction with the City and Guilds of London Institute, under the following heads:

1. Gas-works practice.
2. Gas supply practice.

The course for each of these runs for two years, with an examination at the end of the second year, and comprises instruction in the general principles and elementary details of gas-works practice or gas-supply practice, and in the sciences of mechanics, physics, and chemistry, of which gas manufacture and supply are practical applications. By taking an additional year's tuition, a successful candidate in gas-works practice may be admitted to the examination in gas supply practice, and *vice versâ;* so that in three years anyone desirous and capable of so doing may obtain certificates in both subjects. All certificates gained in these examinations will be endorsed by the Institution of Gas Engineers.

Provision has been made in this section for isolated students—those so unfortunately placed geographically that they cannot possibly attend any of the classes arranged. These may apply for examination to the City and Guilds of London Institute through the local education authority. If the candidate is accepted, and is successful in the examination, he will be awarded a City and Guilds Certificate; but this will not be endorsed by the Institution of Gas Engineers. Any further information regarding these Minor Grouped Courses, together with a list of the schools at which instruction is provided or examinations are held, may be obtained from Mr. C. C. Hawkins.

III. Professional Courses.

The third division is concerned with professional training in both gas engineering and gas supply. Each of these subjects is divided into three grades—the Ordinary, the Higher, and the Diploma.

The regulations for the Ordinary Grade require attendance in a course occupying not less than 150 hours per annum for three years. Such a course includes, in addition to gas engineering and gas supply, instruction in foundation subjects such as mathematics, physics, chemistry, and/or engineering, upon which the successful study and practice of gas engineering or supply depends. At the end of the three years' course the student is examined, and, if successful, receives the Ordinary-Grade Certificate in Gas Engineering or Gas Supply, which indicates the ancillary subjects studied, as well as the degree of success attained in the main subject—namely Distinction, First Class, or Second Class. These Certificates are issued by the Institution of Gas Engineers, signed by the President and Secretary, and endorsed by the Board of Education.

The course for the Higher-Grade Certificate in both gas engineering and gas supply occupies another two years of not less than 150 hours per annum, in which further instruction in the ancillary subjects previously studied, or in alternative subjects, is given, in addition to the main subjects of gas engineering or gas supply. As a general rule it is recommended that a student in gas engineering taking an Ordinary Grade Course in which special emphasis is found to be laid upon chemistry should devote himself to engineering subjects in the Higher Course, and *vice versâ*.

Entrance to the Higher Course is restricted to those who possess either the Ordinary-Grade Certificate, or some equivalent qualification, such as the National Certificate (Ordinary) of the Institution of Mechanical Engineers or of the Institute of Chemistry. No one may be awarded the Higher-Grade Certificate who is not engaged on the practical (as distinguished from the clerical) side of the main subject of study (gas engineering or gas supply). As in the Ordinary Grade, the Higher-Grade Certificate is awarded by the Institution of Gas Engineers, endorsed by the Board of Education, and will denote the class (Distinction, First Class, or Second Class) in which the candidate has been placed, and the ancillary subjects studied.

Courses in one or both of the above subjects and grades are being provided at the following Technical Institutes: Bath Municipal Technical College, Barnsley Technical School, Birmingham Municipal Technical School, Blackburn Municipal Technical College, Bournemouth Municipal College, Bradford Technical College, Bristol Merchant Venturers Technical College, Burnley Municipal College, Derby Municipal Technical College, Dewsbury Technical College, Glasgow Royal Technical College, Halifax Municipal Technical College, Huddersfield Technical College, Leeds Central Technical School, Regent Street Polytechnic and Westminster Technical Institute (London), Manchester Municipal College of Technology, Plymouth Municipal Technical School, Portsmouth Technical College,

Salford Royal Technical College, and Stoke-on-Trent Central School of Science and Technology.

Where convenient and advisable, the earlier years of the course may be taken at other schools, with the previous consent of the Advisory Committee.

The Principal of any of the foregoing schools will be pleased to give the fullest information to intending students.

The exact character of the courses taken varies naturally with local circumstances and conditions. Perusal of the following courses of study which are being taken at three of the above Colleges will, however, be an indication to students of the lines upon which the Education Scheme is being worked.

Typical Courses in Gas Engineering.

	Senior Course.			Advanced Course.	
	1st Year.	2nd Year.	3rd Year.	1st Year.	2nd Year.

It is, of course, understood that the above Senior Courses refer to the Course for the Ordinary-Grade Certificate, and the Advanced Courses to that for the Higher-Grade Certificate.

Section II.

It is hoped that year by year the above list of colleges providing instruction in gas subjects will be gradually increased until personal tuition in these subjects will be within the reasonable reach of all but the most exceptional cases. Meanwhile it is obvious that considerable areas of the country are at present untouched. Provision has therefore to be made for the certification of those to whom attendance at classes in gas engineering or gas supply is absolutely impossible. These are provided for in section II. of the scheme.

Under the provisions of this section, students who can satisfy the Advisory Committee that it is impossible, owing to geographical position, for them to attend the Grouped Courses arranged under section I., and who at the same time are also able to satisfy the Committee, either by the production of certificates gained, or by the voucher of the principal of an approved school, that they have attained the requisite standard in any three of the specified ancillary subjects (mathematics, chemistry, physics, mechanics, machine drawing, building construction, and heat engines) may be allowed to sit for examination in gas engineering or gas supply.

For the Ordinary Grade this requisite standard in ancillary subjects has been defined as "not inferior to that of the third-year senior course of an approved technical school." The examinations are of standard equal to (and are held at the same time as) those under section I. The successful candidate is awarded a Certificate by the Institution of Gas Engineers, signed by the President and Secretary, showing the degree of success obtained, and the ancillary subjects studied, but which is not endorsed by the Board of Education.

The examination is restricted to those who have been engaged on the practical side of the main subject of study (gas engineering or gas supply) for at least one year previously. Forms of application to sit for these examinations, and any further information necessary, may be obtained from the Organizing Secretary, Mr. Walter Hole, "Wharfedale," Barton, Torquay. The forms must be returned not later than the last day of February in any year.

Entrance to the Higher-Grade Examination in either gas engineering or gas supply under section II. is restricted to those who have

(*a*) been engaged on the practical side of the main subject of study (gas engineering or gas supply) for at least three years;

(*b*) obtained the Ordinary-Grade Certificate in the subject of examination; and

(*c*) are able to satisfy the Committee that they have received and profited by further instruction in the ancillary subjects taken for the Ordinary Grade, or, alternatively, in others approved by the Advisory Committee.

The questions in this section are the same as for the corresponding grade in section I., and the examinations are held at the same time. Successful candidates are awarded a Certificate signed by the President and Secretary of the Institution of Gas Engineers, denoting the degree of success obtained (Distinction, First Class, or Second Class) and indicating the ancillary subjects studied; but this Certificate is not endorsed by the Board of Education.

In both the Ordinary and Higher Grades in this section an examination fee of one guinea is charged. Application forms and any further information may be obtained from the Organizing Secretary.

Diploma.

The Diploma is the crown of the whole scheme, and is the highest certification granted within the industry. The Diploma may be obtained in either gas engineering or gas supply, and denotes that the holder not only has high academic attainments, but also possesses practical experience and skill. Examination for the Diploma is restricted to those who

(*a*) are actually engaged in the industry;

(*b*) are 23 years of age or more;

(*c*) have obtained the Higher-Grade Certificate in the subject of examination and the Ordinary-Grade Certificate in the sister subject (gas engineering or gas supply);

(*d*) have passed the Matriculation Examination of any recognized British University, or possess the Higher School Certificate A or B, or have attained other general educational qualifications of not lower standard.

The examination is divided into three portions—viz., the written, the oral, and the presentation of a thesis. The last-mentioned, if the candidate is a gas engineering student, must consist of an original paper on some point of gas-works construction or gas manufacture. If the candidate is a gas supply student, it must take the form of an original paper on some point of gas distribution, supply, or utilization. The thesis must be sent to the Organizing Secretary at least four weeks before the date of the written examination.

The oral portion of the examination is directed to eliciting the candidate's personal experience and capacity to deal with the various difficulties, emergencies, and problems which are continually being met with in actual practice—qualifications which cannot be determined so well by any written paper.

No candidate who already possesses an approved degree in gas engineering in a British University is required to sit for the written portion of the Diploma examination. But he is required to present a thesis or published work of his own; to submit himself to a *viva voce* examination; and to produce evidence of professional experience satisfactory to the Advisory Committee.

As in section II., an examination fee of one guinea is charged in the Diploma division.

Application forms for entrance to the examination, and any further information required, may be obtained from the Organizing Secretary, Mr. Walter Hole, "Wharfedale," Barton, Torquay.

A Meter Connection Protector.—A patent has been taken out in the United States by Mr. G. H. Sauton in connection with a device for completely enclosing and locking the coupling unions or nuts of the connecting pipes of a gas meter, in order to obviate any possibility of tampering with the couplings by unauthorized persons. The enclosing device is fastened by a concealed lock, which it is said will resist all tampering efforts of wires, &c., for the purpose of unfastening it. The intention is to number serially each meter protector, and to supply only one number of each series to any one gas undertaking. Thus, in the event of a customer breaking a protector he will be unable to replace it, as the meter reader will be instructed to insert the number of the protector on his sheet at each reading of the meter. The device is so constructed that it can be preserved whenever a meter is changed.

EASTERN COUNTIES GAS MANAGERS' ASSOCIATION.

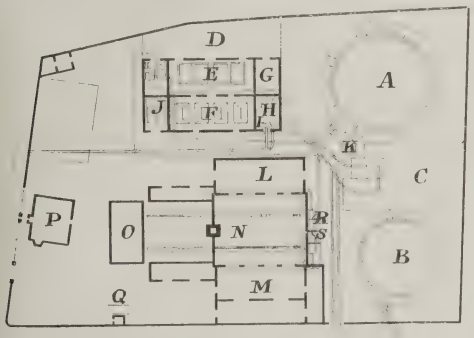
PRESIDENTIAL ADDRESS OF MR. F. A. WEST, OF NEWARK (APRIL 22).

During the 37 years the Eastern Counties Gas Managers' Association has been in existence it has fulfilled its object with distinction. This must be a source of pride and satisfaction to the few remaining original members, who first laid the foundation of this combined effort for progress and the future development of the gas industry in the Eastern Counties.

The District Associations continue to play an important part in the scientific advancement of the industry; and the complex nature of a modern gas engineer's duties tends to make it more necessary than ever to maintain these Associations in a high state of efficiency, so that the problems and experiences met with in various works can be mutually discussed and progress made on the right lines. The more scientific methods of manufacture and distribution, and the wider choice of plant available, make it difficult for an engineer responsible for the economic and sound administration of his undertaking to decide on future extensions. It is only by mutual service to each other that we can maintain the high reputation which has placed the industry in its present sound position.

Newark Gas-Works.

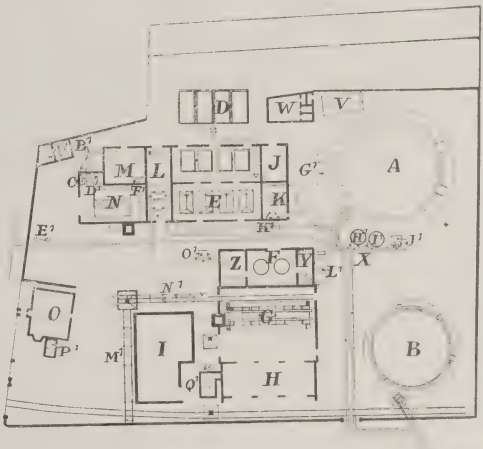
The Newark gas undertaking has been in existence 90 years, and during that period has experienced both prosperous and lean times. You have had an opportunity to-day of examining the present works. When I took charge, they were perhaps one of the last remaining examples of the old school. The main retort house was direct fired and hand charged, and all the rest of the plant dated from the same period. The plant was originally designed for an output of 300,000 c.ft. per day. The entire works have recently been reconstructed on the existing site; and with the exception of utilizing existing buildings, there is practically nothing of the old works left. In the gradual rearrangement of plant on the existing site, and carrying out one's statutory obligations at the same time, advantage cannot always be taken of placing various apparatus in the best relative positions. However, it was a much sounder proposition than erecting a new works on a new site—the only alternative. The two plans show the works as they were and as they are now.

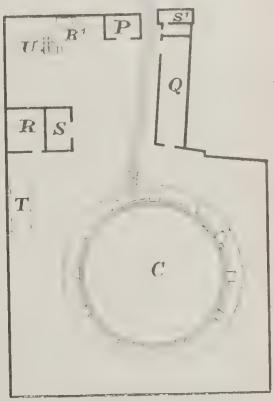


NEWARK GAS-WORKS, 1918.

The existing plant is capable of turning-out over a million c.ft. a day; three-quarters of a million of which is coal gas. The retort house is only 52 ft. wide; and with 20 ft. for the charging machine and 20 ft. for the retorts, there is left 12 ft. for the discharging side. But for a comparatively small retort house with an efficient coke handling plant, it works very satisfactorily. The retorts are 23 in. by 16 in. by 20 ft. long, with 7 in. ascension pipes each side; and the dip-pipes are fitted with Cort's anti-dips. We work with about 12½ cwt. charges in twelve hours, and charge every six hours. We get a very regular flow of gas and even quality, and arrange the retort house governor to give a level gauge in the retorts. The accompanying charts show the vacuum on the retorts and the outlet of the retort house governor, and the calorific value supplied to the town. The whole arrangement is very simple and efficient.

We obtain fairly good results. The average yield for the past twelve months was 72·3 therms, using South Yorkshire and Nottinghamshire coal. Working costs are economical. When four beds are at work, we make 140,000 c.ft. per stoker. This includes everything in connection with the retort house, clinkering furnaces, removing ashes, sweeping up, &c., and coke handling, but does not include elevating coal. One man discharges all the coal and elevates this into the overhead coal hopper. The temperatures are moderate, averaging 1300° to 1330° C. in the combustion chambers; and the charges are not very heavy. But it is hoped, working in this way, to obtain a long life from each setting of retorts. In the ordinary routine of works control, the temperatures of the combustion chambers and draughts on the settings are taken daily, with temperatures and pressures on all the plant throughout the works, sulphur compounds, oxygen content, CO_2, ammonia in clean gas, calorific value, gas engine meters, water meters, and boiler feed water tests for hardness, &c. All these are charted daily, with very little trouble; and, as "coming events cast their shadows before," trouble can often be avoided by giving the charts a few moments' consideration. Analyses of flue gases, complete gas analyses, tests of purifiers and scrubbing plant for efficiency, naphthalene tests, &c., are made whenever required.





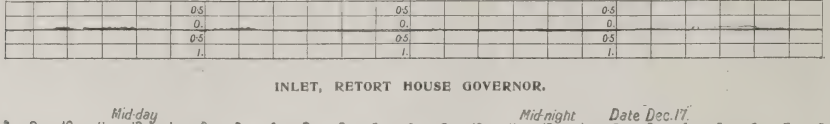
NEWARK GAS-WORKS,

Coke Handling Plant.

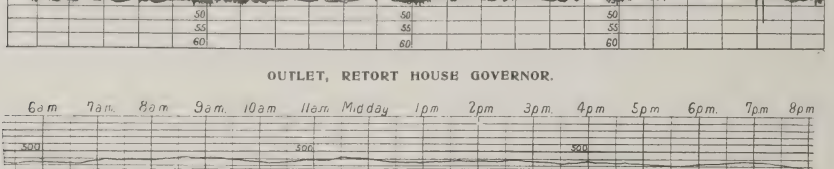
The coke handling plant is, perhaps, somewhat novel. This was made by a local engineering firm, and was constructed largely out of second-hand steel work pulled down from the old retort house. The first cost was low; and there is nothing much to wear out. The stoker on the discharging side can operate it without going outside the retort house. It consists of a bottom discharge bogey running on rails in front of the retort bench, extended up an inclined railway into a coke bunker. The bogey is pulled either way with an endless rope operated by an electric motor, which is controlled by a tramway-type controller in the retort house. The bunker is lined with 3 in. of concrete, and the hopper portion with 3-in. firebricks, to prevent corrosion.

Another travelling skip of half-a-ton capacity runs at right angles, and conveys coke out of the bunker into railway trucks on the siding, and also, if required, stores coke in the yard. The reason a steel bunker was erected instead of ferro-concrete was, as I mentioned before, that practically the whole arrangement was constructed out of old material we had on the works.

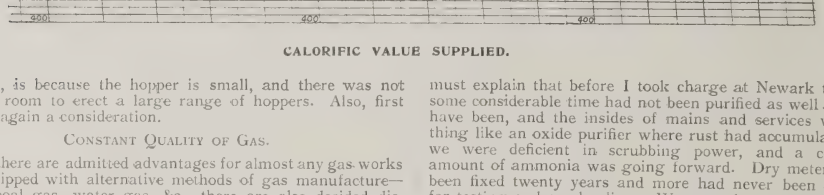
One rather unusual point about it is that the coke is screened as it leaves the hopper, and not before it is put into it. This,



INLET, RETORT HOUSE GOVERNOR.



OUTLET, RETORT HOUSE GOVERNOR.



CALORIFIC VALUE SUPPLIED.

of course, is because the hopper is small, and there was not sufficient room to erect a large range of hoppers. Also, first cost was again a consideration.

Constant Quality of Gas.

While there are admitted advantages for almost any gas-works to be equipped with alternative methods of gas manufacture—such as coal gas, water gas, &c.—there are also decided disadvantages. In the smaller works, it is very rarely an economical proposition to run two different types of plant at the same time. The best efficiency cannot be obtained out of either. It is an established fact that, to obtain the best results out of almost any plant, it should be worked to its full capacity; and, while there is an advantage in being able to control the local residual market to some extent with an auxiliary gas plant, the greatest disadvantage with modern practice is varying quality. Present-day requirements for all-round satisfactory results entail constant pressure, composition, and specific gravity. Varying quality—even only to the extent of a few B.Th.U.—means dissatisfaction on the part of the consumer.

There is a wide difference in some cases between actual loss or leakage in thousands of c.ft. and actual loss in B.Th.U. made and sold on the declared value. There is a tendency to increase pressures gradually, necessitated by increased consumption on existing mains. Probably future developments will see the gradual introduction of higher pressures to ensure that every consumer is supplied at a constant figure throughout the 24 hours, irrespective of the amount he, or any other consumer, happens to be using at any time. Unvarying composition and specific gravity are very real necessities for general satisfaction. This is, perhaps, most noticeable in industrial heating and furnace work. Smaller works that are equipped with one type of plant only for manufacturing gas are in a better position to attain this ideal; and every effort should be made to do so, not only in their own interests, but in the interests of the whole gas industry.

Experience with Low-Grade Gas.

We have gradually increased our declared calorific value from 410 B.Th.U. as we have improved our position. My experience with a low-grade gas has not been of the happiest. While a 400 B.Th.U. gas gives excellent results if the apparatus is adjusted properly, I found the cost of distributing it under modern conditions excessive. We supplied a 410 B.Th.U. gas, for the simple reason that we had no plant to provide any better. Our old retort house was in such a dilapidated condition that it was impossible to work to a higher standard consistently; and for a considerable period we manufactured a large proportion of water gas or complete gasification gas. This relieved our over-taxed purifying plant, and helped us over a difficult coal period. I also seriously considered the possibility of a complete gasification plant, eliminating the retort house altogether; and this method of manufacture was tried-out very thoroughly before deciding to proceed with further alterations to the retort bench. At that period I was optimistic enough to believe this was the future gas, and the most economical to manufacture; but under our present conditions I found it was not the cheapest to sell. As the make per ton went up, the leakage also went up in direct ratio, until we reached the alarming figure of 20 p.ct.; and there seemed to be no finality about it.

After very careful investigation, I came to the conclusion that the only sound way to get back to a normal figure was by increasing the calorific value. Our case may be abnormal, though I cannot but feel that our experiences will also apply to some extent in other places and under similar conditions. I must explain that before I took charge at Newark the gas for some considerable time had not been purified as well as it might have been, and the insides of mains and services were something like an oxide purifier where rust had accumulated. Also, we were deficient in scrubbing power, and a considerable amount of ammonia was going forward. Dry meters that had been fixed twenty years and more had never been brought in for testing and overhauling. We opened our own meter repair shop, so that careful investigation could be made of the meters; and though during the period we were supplying a 410 B.Th.U. gas we sent out for two years a pure gas—that is to say, free from sulphur, SO_2, HCN, &c.—we made no headway with our meters. We sprayed meters with a suitable gas oil, and also pumped a special paraffin into the gas, as we continue to do now for naphthalene.

The insides of the meters were pitted with tiny spots the size of a pin's head, and this on both the leathers and the casing. When the meter was first opened, these appeared like small globules of water; but after the moisture had evaporated, white spots were left on the leather and rusty spots on the tin. The leather in course of time got dry and hard, and the oil all drained to the bottom of the case. The meter began to register fast; then the leather cracked (slightly at first), and the meter gradually registered slower and slower, until ultimately it stopped. The gas seemed to contain an abnormal amount of aqueous vapour; and this, together with a fairly large quantity of ammonia (often 2 to 4 grains per 100 c.ft.), condensed on the insides of the meters. No doubt small particles of rust containing a large percentage of sulphur were also carried forward to the meters from the mains and services. The low-grade gas also appeared to have a tendency to absorb or scrub-out most of the oil from the leathers; and this left them in a state suitable for rapid decay.

It may be possible to distribute a low-grade gas successfully with dry meters, providing every trace of impurity is removed; but I think even then the gas would absorb or tend to release the oil out of the meter leathers. At any rate, since supplying a 475 B.Th.U. gas our leakage has been reduced by 7 p.ct. in two years—from 20 to 13 p.ct.—which I think is sufficient evidence that we are now on the right lines. The hydrocarbons in the richer gas protect the leathers, and the gas apparently does not tend to extract the oils out of the leathers so readily.

While there is no doubt that much of our meter trouble is in our own hands, I am equally certain that much of it is due to the makers. In the course of our investigations I visited many meter works, and the methods of preparing diaphragms vary very considerably. While some makers still follow the old-fashioned way of pickling the leathers for months, others adopt newer methods of preparing them; but the fact remains that, with us at any rate, leathers prepared in the old way are the most satisfactory.

Control of Pipes and Fittings.

The "carbon monoxide bogey" has been allowed to rest lately. In fact, Mr. Butterfield's report has finally killed it, and incidentally has done a great service to the gas industry. The summing-up of this report reflects the modern tendency of our industry's chief aim in one word, "service." Personally, I think we should take more interest in our consumers' gas affairs. Standard specifications should be drawn-up for all fittings and pipes, and every local plumber or ironmonger made to work to them under our supervision. This principle has been adopted in Newark. Some years ago we incorporated in our Act power to specify what size of pipes should be used in houses; and we now require all architects, builders, plumbers, &c., to work to our specification. We have a well-trained inspector periodically calling at every house to inquire, and

actually see for himself that everything is working satisfactorily; and I am quite convinced it is an economical scheme, as many small defects are discovered and put right which would otherwise eventually cause a consumer to be dissatisfied.

The general policy of all up-to-date gas undertakings should be service to the public, if we are to keep abreast with the times and meet competition successfully. The amount of such service will no doubt be increased more and more. It is certainly better to charge an additional 1d. or 2d. per 1000 c.ft. and give thorough satisfaction, than to sell cheaper gas and not trouble about the consumers getting good results. The average gas-fitter is, I believe, a more educated and better trained man than the type of years ago; and many undertakings make special provision for training their fitters in the theory of distribution. It is local plumbers and ironmongers who are generally to blame for unsatisfactory work. Probably one result of Mr. Butterfield's report will enable us to remedy this in the future. Competition is undoubtedly an excellent thing; but it is not in the best interest of anybody to have to compete with the cheap unsatisfactory burners and apparatus on the market, which all gas engineers know to be inefficient. If we are going to be subjected to more regulations and responsibilities, we might do well to imitate the water-works people, and have competent fitters authorized — allowing only such authorized fitters to do gasfitting.

It is placing a large responsibility on gas undertakings to maintain all fittings and apparatus in their district in first-class order; and this may have a tendency to make some consumers careless, from the knowledge that the gas company are responsible for anything that may happen, and not themselves. To carry this scheme to a logical conclusion, it should be made a finable offence if a consumer neglects to notify a gas undertaking when anything is wrong, or if he permits any outside fitter to fix apparatus that is not of approved type. Escapes are sometimes noticed for days without being reported; but I believe in some towns, if a consumer neglects to report a leaking water tap in his house, he is liable to a fine. Many gas companies encourage the police, road men, &c., to report escapes, by giving them a small reward every time a proved escape is reported.

However, the ordinary risks of gas poisoning are very small; and it is quite reasonable to assume that if everybody had an all-gas house, the annual death-rate would be reduced very considerably in this country, by the abolition to an enormous extent of fogs and smoke.

From Company to Corporation.

The Newark gas undertaking is just passing into the hands of the Corporation; and it is interesting to note how this originated. There is no central electricity generating station in Newark, though there are two or three small private companies supplying current for shop lighting. The Corporation were desirous of having their own works; and it was considered that a plant worked in conjunction with the gas-works would be the most economical to commence with, both as regards capital outlay and working costs. As it was considered in Newark that the Gas Company would have too much of a monopoly, the undertaking was offered to the Corporation; and there is no doubt that, if the latter manage the concern carefully, the transfer will benefit Newark in years to come.

While there is much to be said both for and against municipally-owned gas-works, one of the chief drawbacks of company-owned undertakings at present is that there is no really sound system of depreciation of capital, and when a company is faced with a large capital and a collection of old plant the position is serious. This is more pronounced perhaps since the war. Capital costs of plant have increased enormously; and it is conceivable that when large extensions are necessary, due to increased business, the capital costs will increase their capital ratio per million out of all proportion to what they have been used to. This they will probably have to carry for all time. There does not seem to be any probability for many years to come of obtaining the same proportion of plant out of revenue as many works have done in the past.

A municipally-owned works with a sinking fund has an advantage here. Of course, in some cases this advantage is not turned to the best account, if excess profits are used in large sums annually to relieve the rates. The determining factor in turning the scale in favour of gaseous fuel is that of cost; and it is necessary that no obstacle, whether in the form of rate subsidies or anything similar, should be allowed to oppose this policy. Having regard to the true functions of a municipality, the question of mere monetary profit should be quite secondary; and with a view to securing the universal use of gas, with its attendant benefits to the community, it should be sold at the lowest possible price consistent with protecting the ratepayers from any loss.

Electricity in Newark.

It has finally been decided in Newark to purchase electricity in bulk from the Notts and Derby Power Company. Possibly, all circumstances considered, it is the solution from an electrical engineer's point of view; but there is a much broader view —a national outlook on the whole subject. Much has been said and written about super-electrical stations, and how electricity is going to revolutionize this country; but most of these would-be reformers seem to miss the main point. It cannot be repeated too often that the chief natural resource and prime mover in this country is coal. In order to take full advantage of this, and make the best use of it, as much as possible of this coal should be carbonized; electricity being made from the bye-products, either gas or coke.

Electricity can only be viewed in this country as a bye-product of coal; any other way of regarding it is to shut one's eyes to facts. It has been amply proved that our own industry is much more efficient in its utilization of the raw material than is electricity. Of course, in countries where water power and other natural resources are available, the position is entirely different. Most small towns can generate their electricity cheaper at the gas-works, either by gas engines or waste-heat boilers; and when one considers that there is a staff and organization already in existence, it is difficult to see where the economy is in a separate undertaking.

Mr. Chaney suggested some time ago that a Gas Commission should be established to work in conjunction with the Electricity Commissioners. It appears the obvious solution. With a super-generating station equipped with extremely large units and every possible refinement in the boiler and power houses, a thermal efficiency of about 20 p.ct. is obtained in the process of generating electricity from the raw coal by way of steam; and there is no prospect of effecting any great improvement. It seems tragic that this is the best a super-power station can do; 80 p.ct. of the coal used going to waste up the chimney. Possibly in the future power production will be developed by the internal combustion engine, whose higher efficiency will displace the steam engine. Many electricians themselves admit that, unless they can generate current by water or other natural means, they have very little hope of producing much cheaper electricity.

Coal Economy.

The economical use of coal will have to be more seriously considered in this country in the future; and all the help and encouragement possible, both by legislation and otherwise, should be given to the gas industry to produce cheap gas. Low-temperature carbonization continues to make strenuous efforts to prove a commercial success. There is a low-temperature carbonization plant in operation in the Eastern Counties, combined with a complete gasification plant which is intended to replace the existing retort house. Results from this will be watched with interest. Complete gasification would, if carried out on a large enough scale and properly applied, result in an enormous saving of the nation's coal; but the elimination of the retort house, and the general distribution of a gas with comparatively low calorific value, will not come yet.

Perhaps the solution is by enriching with low-temperature gas. Mr. Evans some time ago pointed out, in one of his lectures, that, assuming there were 300 therms in a ton of coal, with modern gas-works practice 72 therms would be recovered as gas, 17 therms as tar, and 199 therms as coke, giving a total of 288 therms. With low-temperature practice 35 therms would be recovered as gas, 26 therms as tar, and 223 therms as coke, giving a total of 284 therms. It would therefore appear that the system is not so efficient at the outset as modern high-temperature carbonization. At Newark we have actually obtained 200 therms per ton of coal in the form of gas out of a complete gasification plant; a combined plant should certainly produce a larger number of therms as gas than modern gas-works practice. Even assuming the total thermal efficiency is somewhat less than present practice, if the capital costs are less and operating costs lower than with a modern retort house, it might be a paying proposition.

Strenuous efforts are constantly being made to produce cheap gas; and the modern tendency seems to favour amalgamation of the smaller concerns with the larger. It is obvious that in many cases economies can be effected and better service given to the public in this way. It is certainly a necessity to practice economy in these days; and we can only view with grave concern the general attitude of labour in this respect. If every labour organization adopted for its motto: "A square deal—a fair day's work for a fair day's pay," we should soon again be on the high road towards prosperity as a nation. The men who work are those who bear the load; and nothing but a policy of national thrift will lift the heavy debt of taxation which is oppressing commercial enterprise.

Future of the Gas Industry.

Apart from efforts to manufacture cheap gas, very real progress is being made in the efficiency of apparatus to use gas. We are having a paper this afternoon on a method of using gas for industrial purposes which claims to be a very great advance on older methods. Sir Arthur Duckham, in a paper at the World Power Conference, pointed out that for many years the low cost of labour and the apparently high cost of coal gas prevented manufacturers from considering the use of the latter, but gradually it was coming to be realized that the actual cost of fuel was not the only consideration, for so much depended upon subsidiary questions—such as transport, storage, and cost of handling and utilization. In an attempt to form a basis as to what industry could afford to pay for gas as compared with solid fuel, he pointed out that a ton of coal has a potential heat value equivalent to 290 therms. Taking the value of coal delivered to a works at 35s. per ton, the cost per therm would be 1·45d. The heating efficiency of the raw coal

fire or furnace is not, on the average, greater than 25 p.ct., whereas the heating efficiency of a gas furnace is 70 p.ct. Taking the cost of gas at 4·4d. per therm, which is the selling price of some undertakings for large quantities, the comparative figures are 5·8d. for coal and 6·28d. for gas for every therm actually utilized. Gas is, therefore, on this basis, under 8 p.ct. more costly than coal as a fuel. This is, no doubt, in many cases easily compensated for by the many advantages attached to the use of gas.

Possibly very large developments in the further use of gas in industry are not far distant; and it only goes to show the growing importance of every undertaking of any size concentrating on the distribution of gas and organizing an efficient distribution department. I feel confident, as every other gas engineer, that the gas industry has a very great future before it. It is quite possible that it will develop into the premier industry in this country, as coal is our greatest national asset, and at present we are showing the nation how to use it in the most economical manner. When it is remembered that there are over 16 million gas cookers and fires in use in this country, and that the Gas Light and Coke Company alone produce in a year approximately as much energy for light, heat, and power as is produced in the form of electricity by the whole of the electrical undertakings in Great Britain, there is no need for the suggestion that gas is on the wane.

Publicity.

I am afraid there is still a great tendency for us, as an industry, to "hide our light under a bushel." We do not shout enough, but are content to go quietly along, letting our goods advertise themselves. Imagine how the "Daily Mail" would advertise the fact if they had a circulation of 16 million copies, or supplied as much printed matter as all the other daily papers in London put together. Too much is left to the "B.C.G.A." Many undertakings are content to pay their annual subscription, and let their publicity work stop there. If every gas undertaking advertised intelligently in the local papers, the "B.C.G.A." could devote more time and energy to telling the country what the gas industry is doing for the nation. We know the usefulness and national importance of our work; but the very fact that we have been in existence over a hundred years is sufficient to lead people to believe that we have had our day, and that it is only a matter of time for the newer arrival to supplant us. Many who consider themselves well informed say as much, and we shall have ourselves to thank if that theory grows.

I am sure that, if the electrical industry in this country could do as much for the conservation of coal and the abolition of the smoke nuisance, the whole country would never be allowed to forget the fact. It would appear that we as an industry are not sufficiently assertive; and probably the majority of us still have a feeling at the back of our minds that advertising is a little *infra dig*. We compromise by producing something very nice and quiet and artistic, and console ourselves by saying that, after all, it does not matter very much—gas advertises itself. Gentlemen, it is a mistake. The time has arrived to let the country know what are our capabilities, and in no uncertain manner. If the business world knew as much about us as we know ourselves, there would be a general demand to gasify the country instead of electrifying it; and it behoves us therefore to educate politicians.

Political influence is responsible largely for the present state of affairs; and it seems a remarkable thing that gentlemen with no real knowledge of the subject should be in a position to force the country into a policy which will eventually mean an expenditure of many millions, with no corresponding advantage. There has been of late a strong tendency among politicians to boost electricity at all costs; and I believe that much of that tendency has been caused through lack of knowledge. There is a large field for both gas and electricity, in which both can work for economy, efficiency, and the improvement of the atmosphere of our towns. Anything that will assist in bringing more sunshine into our lives should be welcomed and encouraged, not for our own sakes, but for the future health, wealth, and prosperity of the nation. The sooner this fact is realized, and coal is viewed as stored sunlight, the happier and better will it be for future generations.

"B.C.G.A." South-Western District Conference.—Arrangements have been made for a British Commercial Gas Association South-Western District Conference to be held in the Plume of Feathers Hotel, Minehead, on Friday, May 8, under the presidency of Mr. J. H. Ellis, President of the "B.C.G.A.," and Chairman of the Plymouth and Stonehouse Gas Light and Coke Company. In the morning Mr. John Burgess, J.P. (the Chairman of the Minehead Gas Light and Coke Company, Ltd.), will welcome the visitors, and Mr. Edwin P. Vince (the Company's Manager and Secretary) will read a paper entitled "Local Publicity and Service Methods of a Fifty Million Works." Luncheon will be followed by a public conference in Newcombe's Café, The Parade, when an address on "The Modern Labour-Saving House" will be given by Mrs. Robert Noble (Consultant on Home Hygiene, Furnishing, and Equipment).

CONSTITUTION OF COAL.

At a meeting of the London Section of the Society of Chemical Industry, held at the Royal Society of Arts, Adelphi, on Monday evening, April 6, Prof. W. A. Bone lectured on the subject of "The Constitution of Coal"—indicating some of the lines of inquiry into the matter which have hitherto been pursued, and offering some suggestions with regard to future investigations.

At the outset, he informed his audience that he was not going to tell them what is the constitution of coal, for the simple reason that he did not know. Of late years there has been a great deal of research on the subject of coal—certainly it has not been in want of investigators or of money to urge it forward. Yet, if one took a candid view of the situation, one would conclude that not much of fundamental importance is being found out about the chemical constitution of coal. Very little more is known of this matter to-day than was the case twenty years ago. For the fact that present research is not making such progress as might be wished, he did not think that the researchers were to be blamed; but he suggested that the time has arrived when the organic chemist must take up the matter. The fact must never be lost sight of that, coal being an organic substance, its constitution can only be finally determined by methods adopted with other organic substances. He explained that in this country there does not exist a very wide range of coals, and put forward the view that the subject has suffered from the fact that many of the investigators have only been considering coal as it is known and used here. They should not limit themselves to bituminous coals. In other countries there are many varieties of less matured coals; and these also must be considered in order to arrive at a satisfactory explanation of the chemical constitution of coal.

At one point in his lecture, Prof. Bone said he thought it had been suggested that the cause of the coking properties of coal resides in the vitrain; but personally he did not believe this, and he had the best of reasons for not believing it. He directed attention to samples of coal which, though they may contain considerable quantities of the jet-like substance called vitrain, will not coke at all. It may be, he added, that there is a connection in the case of some of the bituminous coals, but he doubted it. One must look elsewhere for the cause of the coking properties of coal.

Showing by the aid of lantern slides results which have been secured by him, Prof. Bone explained that he does not like the use of pyridine as a coal solvent, so he has ceased to employ it for the purpose. He prefers in its place to use benzene under very high pressure. There is no gas evolved during the benzene extraction in the case of bituminous coals. There may be some slight change in the coal substance, but it does not involve any breaking-down of the coal structure itself. The crude extract is obtained in this way, and then fractionated in a manner which he described.

Some discussion followed the lecture—or "conversation," as Prof. Bone preferred to term it. Dr. Lessing remarked that, the further one went into coal research, the greater seemed to be the field of ignorance one met with. It would be only by the combined work of a great many investigators that they would eventually be able to see a little more clearly. Prof. Bone had rightly laid stress on the fact that the organic chemist must take a part in this research. Without paying considerable attention to the question of coal formation, it would be impossible to get nearer the subject of constitution, because the two were closely linked together. He (Dr. Lessing) was responsible for attributing the coking properties of coal to the clarain and vitrain portion. There was no difference in fact between Prof. Bone and himself; for the component in younger coals from which clarain and vitrain were formed was non-coking. Moreover, the material into which these components changed on further maturing, say into anthracite, was also devoid of coking properties. Dr. Scholtz expressed the opinion that the substitution of benzene for pyridine was a very important step. Dr. Harold G. Colman said much good work had been done, and made reference to the products resulting from the extraction with benzene, which he agreed was a great improvement on extraction with pyridine; but he thought that some decomposition of the coal must have taken place under the conditions of the experiment. Prof. Bone, in reply, said he adopted benzene as being the least objectionable substance for the purpose.

"An Introduction to Technical Drawing."—This is the title of a work by W. Abbott, B.Sc., which is to be published by Messrs. Blackie & Son, Ltd., No. 50, Old Bailey, E.C. 4, in three parts at 2s. 6d. net each. The publication is designed to meet secondary and central school requirements; ample work having been included in the three parts to cover a three years' course. After completing the course, students will be in a position to begin specialized work in one or more branches of technical drawing—machine design and construction, building construction, &c. The author has included a good deal of plane and solid geometry in the course. We have received a copy of Part I., and feel sure that it will prove exceedingly useful.

SAFEGUARDING OF GAS ENGINES.

A great deal of practical information was contained in a paper which Mr. G. Stevenson Taylor, O.B.E., A.R.C.Sc., A.M.I.Mech.E. (H.M. Senior Engineering Inspector of Factories), read at the last meeting—held at St. Bride's Institute, E.C.—of the Institution of Engineers-in-Charge.

The subject of the paper (which was illustrated by a series of lantern slides) was "The Safeguarding of Prime Movers and Transmission Machinery;" and, of course, a good deal of consideration was given to the proper fencing-off or covering-in of the moving parts of gas and oil engines. The author pointed out that the requirement as to fencing of every part of a water wheel or engine and every flywheel is absolute, though it may be so situated that no danger or liability to accident is likely to ensue from its position. Similarly it has been held that the bevel gearing of an engine governor must be securely fenced, though the engine itself was fenced. Again, all machinery from which, in the ordinary course of working, danger may reasonably be anticipated—though such danger may arise by reason only of careless working or of external causes—must be securely fenced. Upon the occupier of every factory rests the responsibility of ensuring that his machinery is securely fenced; but exactly what may be regarded as secure fencing for a particular engine or part of machinery will depend to some extent on local circumstances and the knowledge and experience of the person concerned.

Considering more particularly the safeguarding of the parts of prime movers and transmission machinery, the following are regarded as the essentials of a satisfactory safeguard:

(1) It should prevent access to the dangerous part so long as the danger exists.
(2) It should be constructed of such materials, and in such a manner, as to withstand the wear and tear to which it is likely to be subjected.
(3) Wherever practicable, it should form an integral part of the engine or machinery, and have been considered in its design.
(4) Its removal should not be necessary for the purpose of lubricating any part of the engine or machinery, or for changing belts, gears, &c.

The selection of a suitable material for the construction of safeguards is a matter of the utmost importance, but unfortunately often receives very scant attention. When substantially and firmly constructed of sound timber, wooden guards for such parts of machinery as pullevs, belts, small flywheels, and shafting can be both neat and effective. However, the use of wood for guards has several disadvantages. It is easily splintered or broken, and thus unsuitable for rough usage; it readily absorbs liquids, and is therefore unsuitable for positions where it may be splashed with oil, &c.; and it increases the fire risk. Cast iron is a particularly suitable material for the safeguarding of many dangerous parts of engines. Guards of this material can be designed so as to form an integral part of the engine, and to meet all other conditions. Sheet metal, of suitable gauge, is an excellent material for guards—especially for those required on existing machinery, though there is no difficulty in making provision for such guards in the design of a machine. A sheet-metal guard should be supported on a strong framework of angle bar or rod, and it should be made by skilled workmen. Rods, tubes, and bars of metal are suitable for some classes of safeguards, particularly those which are effective at a distance of about 18 in. from the part of machinery to be guarded. Unless this is the case, these materials should not be used, except with small spacing, or in conjunction with sheet metal, wire work, or expanded metal. Wire work and expanded metal are similar materials for guard construction, except that expanded metal often has a somewhat sharp edge, which may cause cuts. Much may be said in favour of these materials if they are used of suitable gauge and mesh, and properly secured to strong framework. Millboard, *papier mâché*, and similar materials, have mainly been used in the construction of some patented types of safeguards for revolving shafting. Where, as on overhead shafting, they are not subjected to rough usage, such safeguards have proved effective, and have lasted for some time.

Dealing with individual safeguards, Mr. Taylor said it is very desirable that, wherever practicable, an engine should be installed in an engine house. The side of such a house often constitutes part of the fencing for a flywheel or other moving part of the engine. The use of wood for the fencing of engines is not recommended, for reasons already stated, and also because it is likely to be of inadequate strength. Flywheels—and particularly those on large gas engines—are frequently found with excellent fencing on the outside, but on the side near the crank a single rail placed 6 or 7 in. from the flywheel has been regarded as sufficient, though the attendant has to approach this side at intervals in order to feel the bearing. In all such cases additional guards of sheet metal or wire mesh extending just beyond the crank shaft bearing are necessary. A number of horizontal gas and oil engines are now supplied by the makers with the cranks, and in some cases the connecting rods, enclosed in sheet-metal casings. This system has also been adopted by some makers for these parts on large horizontal steam engines. Many high-speed vertical steam engines have the crank chambers completely enclosed; and with the exception of the flywheel and governor there are no exposed moving parts on these engines. The same is true of many large vertical gas and oil engines.

On steam, gas, and oil engines, where the valves are operated by means of a separate valve, cam, or lay shaft, this is usually driven from the crankshaft by means of bevel, skew, or worm gears. These gears should be guarded by means of sheet or cast-metal casings; and such casings are generally fitted by the engine makers. A certain number of accidents have occurred on the cam shafts of gas and oil engines, though many engine makers and users appear to be unaware of this danger. These shafts are usually carried fairly close to the engine framing, and are best fenced either by means of a sheet-metal apron guard attached to the framing or by enclosure in a metal casing. On vertical gas and oil engines—including Diesel engines—the vertical or inclined shaft transmitting motion from the main engine to the cam shaft should be encased. This is done by several engine makers.

Many of the fatal accidents in connection with engines are due to the bursting of flywheels caused by failures of governors. Some of these arise from faulty design, and others from wear or slackness. The maintenance of the governor and governor gear in proper working order is therefore a matter of primary importance. Wherever possible, some trip device, speed control, or stop motion should be fitted, in order to prevent racing of the engine in the event of the governor failing. It is not uncommon to find engines with a length of the main shaft projecting beyond the flywheel, or even beyond the outer flywheel bearing. Such shafting should, of course, always be fenced; and this is best done by means of a tube or sleeve. Any other accessible parts of the main shaft should be guarded in a similar manner, or by means of suitable rail fencing.

Air-Driven Wire Brushes for Holder Cleaning.

A short time ago, the People's Gas Light and Coke Company, of Chicago, were confronted with the problem of how best to clean the outer surface of one of their 5 million c.ft. holders. Describing the method adopted, the "Compressed Air Magazine" states that the holder had not been painted for more than two years, and had reached a state which called for prompt and radical attention. The two bottom lifts were in a particularly bad way. In consequence of the action of the water and the air, the paint had become blistered, and much of the metal was covered with a thick coating of rust. The three upper lifts were not so much in need of attention, and could be made ready for re-painting with comparatively little work. Therefore the cleaning of these lifts was accomplished by hand. The two bottom lifts were cleaned with air-operated wire brushes; the air for the purpose being furnished by a portable compressor. The wire brushes did their work well; and the foreman in charge declared that it would not have been possible to do it satisfactorily by hand. The metal between the rivets was deeply corroded; but the high speed of the pneumatic wire brushes enabled them to get between the rivets and clear away the rust and scale preparatory to painting. Furthermore, the mechanical brushes saved a great deal of time, and lightened the work of the men.

Gas Used in Producing Shell Flakes.—A Monterey (California) inventor has, says the "American Gas Journal," perfected a method for converting abalone shells into beautiful flakes for stucco work. Each year abalone produces a layer of new shell. The inventor treats the shell chemically, and then places it in a special gas-heated stove, where it is permitted to remain for a certain length of time, which results in the disintegration of the various layers of shell. After this the shell is run through a grinder, which flakes it, producing a Roman gold effect that is permanent. In applying the flakes for stucco work, the walls are plastered, and then the flakes are pushed by hand or compressed air into the wet stucco.

The Late Mr. H. E. Jones.—The April issue of the "Wandgas Magazine"—the Journal of the Wandsworth, Wimbledon, and Epsom District Gas Company—contains affectionate references to the late Chairman by the Chief Engineer and the Secretary. Mr. C. M. Croft says of Mr. Jones: "Always proud of his profession, in which he obtained the highest honour; always busy, but never too busy to help another, he leaves this world the better for his long life, spent in untiring service for the public good—the ideal of every true gentleman. The loss to us is irreparable; but his memory will be a lasting pleasure, and his life an example and ideal for us all." Mr. C. W. Braine says: "There was nothing of unctuous piety about him, and he did not wear his heart on his sleeve. He was intensely human. His friend, the Rev. Hugh Chapman, well expressed his attitude towards religion in his address at the memorial service in London, and spoke of a quality of justice, coupled with good fellowship. These were not mere words."

THE HYDROGENATION AND LIQUEFACTION OF COAL.

Two years ago H. G. Shatwell and J. Ivon Graham commenced a series of investigations on this subject; and the results of their work have been published in "Fuel in Science and Practice." Concerning the hydrogenation of coal, Bergius has drawn what appears to the authors to be a somewhat artificial line of demarcation between coals containing less than 85 p.ct. of carbon (ash-free basis) and those containing more than this amount. The former he considers may be readily converted into a thick oil under certain experimental conditions, leaving nothing but the ash; while of the latter only a certain proportion is liquefied. As it seemed possible that the coals of less than 85 p.ct. carbon content used by Bergius were lignitic in character, while those of over 85 p.ct. resembled steam coals of high carbon content, the authors considered that the treatment of a highly oxygenated non-coking bituminous coal would be of special interest, in view of the desirability of finding for such coals an industrial application apart from their use as a fuel for household purposes. It was decided to test the action of hydrogen at high pressures (100 atmospheres and over) and at a temperature in the neighbourhood of 400° C., on the microscopic ingredients. A series of several experiments showed that hydrogenation of clarain in the dry state was unsuccessful from the point of view of oil formation. In subsequent experiments a liquid medium—phenol, except in one instance—was employed, in which clarain, durain, and fusain were treated.

Hydrogenation with Gas Oil as Medium.

In the first experiment, 150 grammes of coal and 400 c.c. of a gas oil were heated with hydrogen during 4 hours to a maximum temperature of 415° C. and a maximum pressure of 110 atmospheres. After cooling, the residual gas was released, and treatment continued with fresh hydrogen during 3·5 hours. The product was partly solid and partly liquid. Approximately 40 p.ct. of the coal was converted into liquid.

Hydrogenation with Phenol as Medium.

Clarain hydrogenated in the presence of phenol during 3 hours at 416° C. and 123 atmospheres caused absorption of hydrogen of over 2 p.ct. The recovered material was 56·2 p.ct. soluble in phenol and 20 p.ct. insoluble; there being a loss of 23·8 p.ct. The soluble portion yielded 53 p.ct. to chloroform with 47 p.ct. insoluble, each portion being a brown solid, but that soluble in chloroform having a low melting point. The chloroform-soluble powder contained about 7 p.ct. of hydrogen. This product represented 29·6 p.ct. on the original clarain. Hydrogenated in the presence of phenol for 13 hours, clarain gave 37·7 p.ct. of oil soluble in ether. Heated in the presence of phenol in an atmosphere of nitrogen, clarain gave a yield of 8·3 p.ct. of material soluble in phenol.

Durain was hydrogenated in the presence of phenol during four days, a fresh supply of hydrogen being admitted at the beginning of each day's run. It was found that 4·49 p.ct. of hydrogen had been absorbed. The product consisted of 37·5 p.ct. insoluble residue, 7·5 p.ct. of a brown powder soluble in phenol, but insoluble in ether, and 37·5 p.ct. of an oil soluble in ether; there being a loss of 17·2 p.ct.

Fusain.—The fusain was a soft variety of high carbon content obtained from the No. 2 Rhondda seam, South Wales. Hydrogenated under the same conditions as employed with durain, very little change took place, there being recovered 95 p.ct. of an insoluble residue which appeared to be but little altered.

Hydrogenation of a Coal of High Carbon Content.—This sample from the Graigola seam, South Wales, had the following ultimate analysis: Carbon, 91·54; hydrogen, 4·32; sulphur, 0·84; nitrogen, 1·45; and oxygen, 1·85 p.ct. Hydrogenated in the presence of phenol during 9 hours at a maximum temperature of 430° C. and a maximum pressure of 137 atmospheres (average about 130), 55·4 p.ct. was found to be soluble in phenol, of which 47 p.ct. was soluble in ether—*i.e.*, 26 p.ct. on the original coal (on an ash-free dry basis). Heated at ordinary pressures to 600° C., this coal gave only 2 p.ct. of tar oil and water, very slight decomposition taking place up to 420° C.

General Conclusions.

(1) The possibility of hydrogenating coal under high pressures and at temperatures between 400° and 436° C. has been definitely confirmed, and substantial yields of liquid products have been obtained.

(2) The nature of the liquids so prepared has not been elucidated. They appear to contain oxygen; and it will be a problem for future investigation to determine if this oxygen is eliminated by further hydrogenation, and hydrocarbons thereby obtained.

(3) The statement by Bergius that coal containing more than 85 p.ct. of carbon is difficult to liquefy is refuted. South Wales coal appeared to be hydrogenated almost as readily as South Staffordshire coals, whereas the fusain experimented with was relatively inert.

(4) The nature of the action of phenol or a mineral oil in accelerating liquefaction is not clear. It was thought that the liquid medium might exert a solvent action on the coal, and that hydrogenation of the coal material in solution would then proceed readily. Experiments, however, prove that this view, as regards the clarain used, is untenable, while the work of Illingworth suggests that it is equally invalid with the coal from the Graigola seam. In the light of some of the results, it seems probable that hydrogenation of coal can take place in the absence of a liquid medium, but that the viscous liquids produced cover the surface of the coal particles and prevent further access of hydrogen. The presence of a solvent will remove the hydrogenated product, thus leaving a new surface exposed to the action of the hydrogen.

(5) It is significant that the yields of products soluble in phenol from the clarain and durain are approximately the same, and that the liquids obtained give almost identical analytical figures. This would appear to be further evidence in support of the view put forward by Tideswell and Wheeler that the clarain and durain from the same coal contain constituents of similar chemical type.

(6) The heavy losses experienced in the treatment of the clarain and durain (both containing substantial proportions of oxygen) are due to excessive gas formation, the production of water, and probably also to the formation of phenols, which were removed in the subsequent technique.

SMOKELESS FUEL AND OIL.

A Meeting of the Manchester Section of the Society of Chemical Industry was held at the Textile Institute, Manchester, on Friday, April 3—Dr. H. Levinstein presiding. A paper entitled "Smokeless Fuel and Oil" was read by Dr. C. H. Lander, Director of Fuel Research in the Department of Scientific and Industrial Research.

The lecturer said that, in 1890, the late Mr. Scott-Moncrieff proposed to carbonize coal, or to make a fuel which he hoped would be a better fuel than gas coke, by withdrawing gas coke from the retorts before it was properly carbonized. This was the germ of the low-temperature carbonization process. It was not, however, until 1906, when the late Mr. Thomas Parker, of Birmingham, took out a patent for Coalite, that the subject received special attention. In 1912 the advantages of such a process were realized from a different angle. The Rt. Hon. Winston Churchill, who was then at the Admiralty, appointed a Committee, under the late Lord Fisher, to go into the question of fuel for the engines of the Navy. At that time there was a possibility of Diesel engines being used in the Navy. That Committee went very carefully into the question of the possibility of providing a home supply of fuel oil. There were no known natural oil supplies in this country capable of serious commercial exploitation. The Scottish shale oil industry survived with difficulty; and both the quantity and the quality of its output were gradually diminishing. The large shale deposits of Norfolk and Kimmeridge, though fairly rich, were not suggested as a possible source of oil supply for this country. The Commission were therefore brought back to the consideration of coal. Two distinct industries were concerned with the carbonization of coal—the metallurgical coke industry and the gas industry. After considering the possibilities, the Commission rather negatived the idea of further supplies of oil being obtained from these two industries in the form in which they existed. Of course, any new industry would probably knit itself on to the two older ones. In 1913, the Commission reported that the most hopeful method of obtaining adequate supplies of fuel oil for the Navy and Mercantile Marine during peace-time, and to a certain extent in war-time, lay in following up the suggestions of Parker for the production of Coalite. Large quantities of oil could then be obtained, by ordinary carbonization methods, together with some gas. There were 35 to 40 million tons of coal per annum burned in the domestic grates of this country, with enormous waste from both the thermal and the chemical points of view. The more valuable of the constituents of the coal simply went up the chimney, polluting the atmosphere, and causing great damage. If this enormous amount of coal could be diverted through some carbonization process in such a manner as to produce the maximum amount of oil, the minimum amount of gas, and a good smokeless fuel, great advantage would result. Dr. Lander then explained the work done at H.M. Fuel Research Station at East Greenwich.

At the conclusion of his paper, the lecturer referred to the Bergius process. A great deal of interest was being taken in this matter; and the plant was extremely interesting. As a matter of fact, the Bergius Company were seeking for a cheaper raw material than oil. Some people said that the so-called hydrogenation of oil was simply pressure-cracking. There was, indeed, a controversy as to whether it really was hydrogenation. The whole problem was being carefully investigated in Germany.

Mr. A. F. Browne, whose death occurred recently, at the age of 74, left estate of the gross value of £7712, with net personalty £7571.

LONDON AND SOUTHERN DISTRICT JUNIOR GAS ASSOCIATION.

On Friday last, April 17, members of the Association met the Westminster Technical Institute, Vincent Square, W. 1, to hear and discuss a paper on "Fuel in Industry" by Mr. Dean Chandler, who is in charge of the Industrial Furnace Laboratories of the South Metropolitan Gas Company. The paper was accompanied by an index of articles on the industrial uses of gas which have appeared from time to time in the Journal," and also by a series of interesting photographs of gas furnaces. It has not been possible to publish all these illustrations; but a good selection is reproduced.

Mr. W. Newton Booth, who occupied the chair, in introducing Mr. Chandler, emphasized the importance of the use of own gas as an industrial fuel.

FUEL IN INDUSTRY.

By Dean Chandler, of the South Metropolitan Gas Company.

[Extracted.]

The problem to-day is to determine the best and most economical methods of using our coal. Briefly, there are four methods at our disposal:

1. It may be consumed in the raw state in domestic grates and industrial furnaces.
2. It may be wholly converted into gas in suitable producers, as originally proposed by Mond.
3. It may be burnt in pulverized form.
4. It may be subjected to processes of distillation, known as carbonization.

It is generally conceded that (1) is extremely wasteful and often inimical to health. Cases in London have come to my notice where 5 therms have been used in the form of raw coal to do the work which has subsequently been accomplished by 1 therm by means of town gas. Alternatives (2) and (3) are for certain large-scale operations justified, providing the right class of coal is employed for the purpose. Alternative (4) is, however, the rational method of treating bituminous coal—namely, to subject it to a heat-treatment process by which it is possible to recover all those valuable distillates which are otherwise lost when raw coal is burnt. At present only about 30 million tons in the United Kingdom are so treated—10½ million tons at gas-works and 13½ million tons by coke-oven plants.

Unfortunately for the electrical industry, the generation of electric energy must be classed under (1), since the general practice to-day is to burn raw coal for this purpose. This common

TYRE HEATING FURNACE.

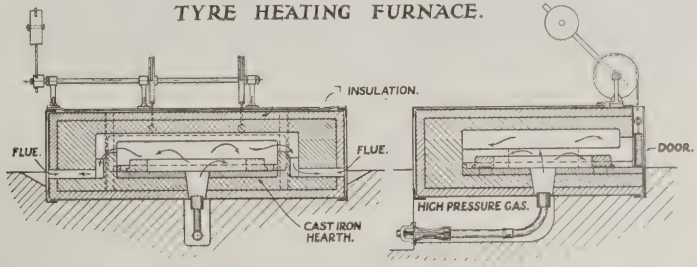


FIG. 1.

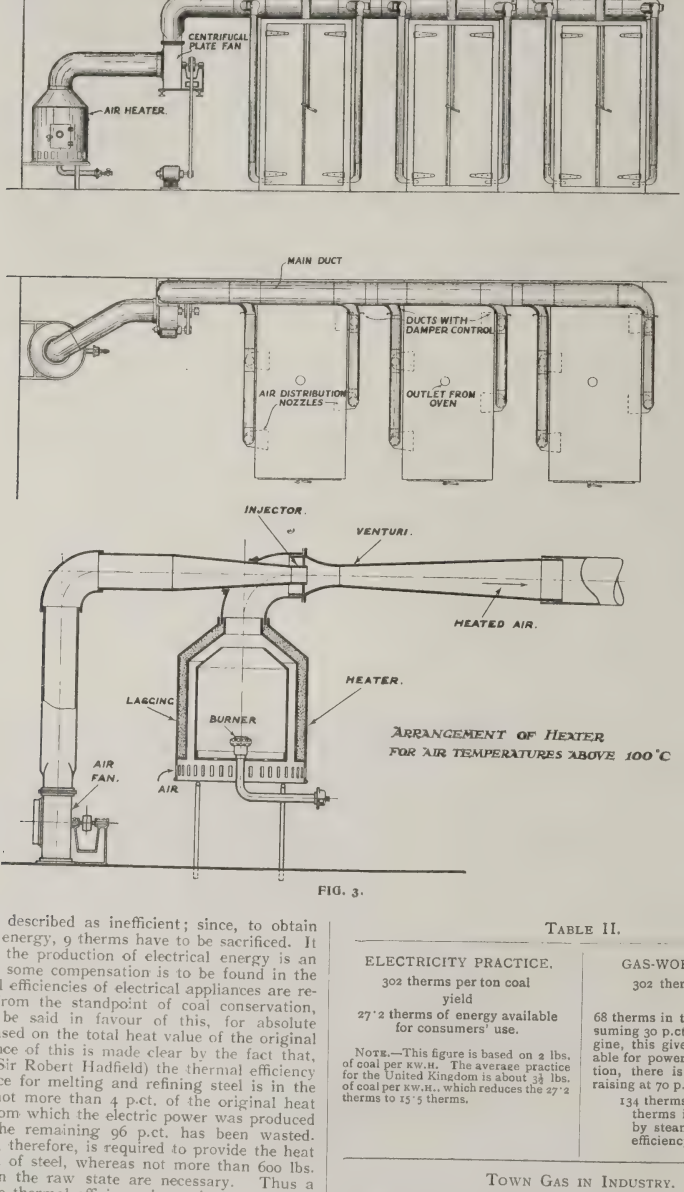

FIG. 3.

method can only be described as inefficient; since, to obtain a therm of electrical energy, 9 therms have to be sacrificed. It is said that, though the production of electrical energy is an extravagant process, some compensation is to be found in the fact that the thermal efficiencies of electrical appliances are remarkably high. From the standpoint of coal conservation, however, little can be said in favour of this, for absolute efficiency must be based on the total heat value of the original coal. The significance of this is made clear by the fact that, while (according to Sir Robert Hadfield) the thermal efficiency of the electric furnace for melting and refining steel is in the region of 47 p.ct., not more than 4 p.ct. of the original heat energy of the coal from which the electric power was produced is actually used. The remaining 96 p.ct. has been wasted. Nearly 1 ton of coal, therefore, is required to provide the heat energy to melt 1 ton of steel, whereas not more than 600 lbs. of coal when used in the raw state are necessary. Thus a much higher absolute thermal efficiency is attainable by burning raw coal.

A comparison of the fuel required for heating 1 ton of steel to 900° C. by coal gas and electricity is given in Table I.

TABLE I.—*Comparison for Heating 1 Ton of Steel to 900° C.*

Fuel.	Therms Used.	Efficiency. P.Ct.	Pounds of Coal Used at Station per Ton Steel Treated.
Coal gas	17·9	32·0	560 lbs.* (used at gas-works)
Electricity	10·3	54·0	851 lbs. (used at electricity works)

NOTE.—* 560 lbs. at gas-works yields 280 lbs. of coke for sale, equal to 33·4 therms. Assuming that coke fired furnaces are only half as efficient as gas-fired furnaces, then a further 0·93 ton of steel could be heated, making a total of 1·93 tons for the expenditure of 560 lbs. coal at the gas-works, then $\frac{560}{1·93}$ gves 290 lbs. per ton used in the gas works. In addition, chemical products are recovered.

TABLE II.

ELECTRICITY PRACTICE.	GAS-WORKS PRACTICE.
302 therms per ton coal	302 therms per ton coal
yield	yield
27·2 therms of energy available for consumers' use.	68 therms in the form of gas. Assuming 30 p.ct. efficiency of gas engine, this gives 20·4 therms available for power purposes. In addition, there is available for steam raising at 70 p.ct. boiler efficiency:
NOTE.—This figure is based on 2 lbs. of coal per KW.H. The average practice for the United Kingdom is about 3¼ lbs. of coal per KW.H., which reduces the 27·2 therms to 15·5 therms.	134 therms in coke, giving 93 8 therms in steam, which give by steam engine at 20 p.ct. efficiency 18·8 therms.

TOWN GAS IN INDUSTRY.

The fuel *par excellence* for industrial heating is gaseous, and there can be little doubt that energy in this form is destined increasingly to supersede solid fuel for a large number of purposes, because of its cleanliness, convenience, constancy of supply, and uniform quality. The use of town gas in all branches of engineering and industrial activity was largely a war-time development, and resulted from the demand for a considerable increase in output of materials of every description. It was thought in some quarters that the industrial load which had been built-up during the war would, after the Armistice, decline and be finally lost; but the advantages of the use of gas as a fuel for a hundred-and-one purposes had been conclusively demonstrated, and its future was thereby assured. Of course, it was to be expected that a sudden drop in the load would occur immediately after the cessation of fighting; but with the return of more normal conditions in industry, the temporary set-back has gradually been made good.

Ten years' experience has taught that one of the essentials for the successful advocacy of gas for industrial purposes is that this branch of business must be handled by men who possess

FIG. 4.—Gas-fired plant for heating air used in drying painted and varnished tinned plates. The heating ovens have a total capacity of 3000 c.ft. A volume of about 120,000 c.ft. of air is raised to about 200° Fahr. per hour; and this maintains a temperature of about 160° Fahr. in the ovens. The maximum consumption of the plant is about 3·7 therms per hour.

more than the ordinary qualifications of salesmen. This is a specialist's business, and it is hopeless to expect a healthy and progressive development if it is left in the hands of those who have but a hazy idea of the basic principles upon which the efficient use of gas as a fuel depends. There must be a common ground of understanding upon which the gas salesman and the works technologist can meet, in order that all the facts with regard to any particular problem may be properly correlated. This is only possible when the representative of a gas company possesses the requisite knowledge. A clear understanding of the basic principles of combustion and of scientific furnace control is essential. The physical and chemical properties of the various grades of fuel should be known; and such information should always be ready to hand. But in addition to an all-round technical knowledge of matters relating to fuels and their combustion, some knowledge of metallurgy and of the more common industrial processes is an invaluable asset, and may be acquired by a study of some of the hundred-and-one books at everyone's disposal to-day.

A matter of vital importance is co-ordination of effort on the part of the commercial and technical staffs. Success very largely depends upon goodwill between the commercial representative and the practical men who should be engaged in the business. The practical technician has always to remember that the man who is canvassing for gas as a fuel has, in the long run, to depend for success upon the gas-consuming appliances which are at his disposal. The real crux of the problem so far as the use of gas as a fuel is concerned is cost. At a time when manufacturers were pressed by the urgency of war, fuel costs became a secondary matter—the problem was simply a question of output. To-day, however, industry is on a strictly competitive basis, and fuel cost is of vital importance, and a question of greatest concern to gas furnace designers. It is incumbent upon the gas furnace and appliance engineer to give the strictest attention to such matters as the combustion efficiencies of the various methods of burning gas and the relative merits of the alternative systems available, the judicious selection of which when applied to a particular process may have a considerable bearing on fuel cost. One of the chief factors requiring consideration in what might be called scientific furnace design is the proportion of air to combustible gas. The fuel losses due to excess air may be considerable. Much can be done to effect a substantial economy by detailed attention to this important matter. It is surprising the extent to which heat energy is dissipated from the average gas fuel furnace. There is, however, no reason for a continuance of this state of affairs. There are many excellent insulating materials at our disposal, the use of which will go far to reduce the consumption of fuel. I have seen gas-fired furnaces concerning which one might be pardoned for assuming that they had been constructed for the purpose of performing the function of a domestic gas radiator, so effective were they in warming the room. As a resuk of tests carried out on lagged and unlagged muffle furnaces, it was found that, after the gas had been turned off for a period of eight hours, the temperature inside the muffle with lagging was 480° C., inside that without lagging only 250° C.

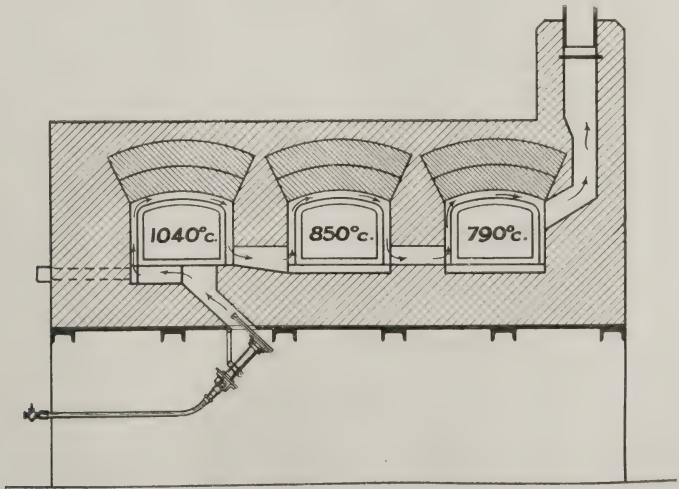

FIG. 5.

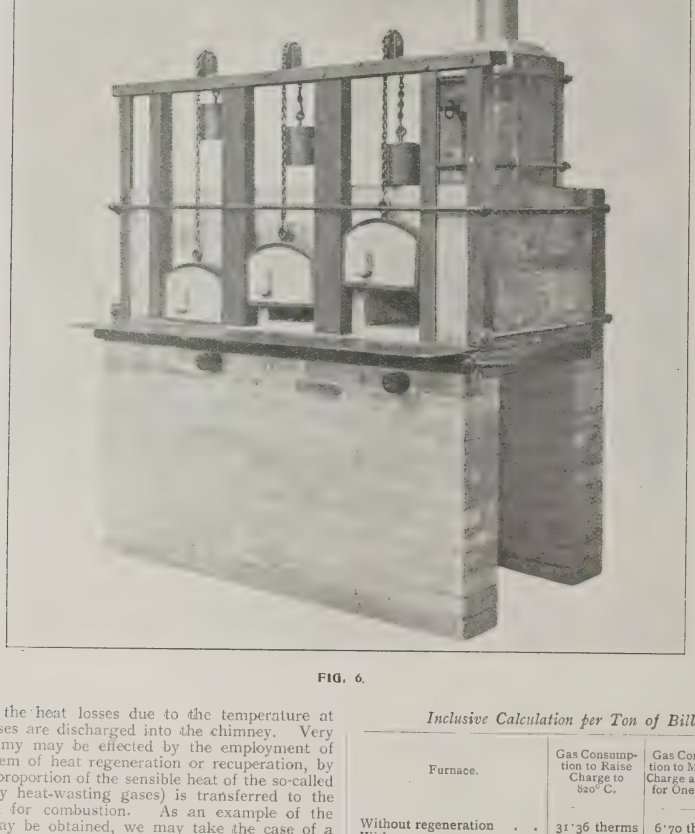

FIG. 6.

Then there are the heat losses due to the temperature at which the flue gases are discharged into the chimney. Very considerable economy may be effected by the employment of some suitable system of heat regeneration or recuperation, by means of which a proportion of the sensible heat of the so-called waste gases (really heat-wasting gases) is transferred to the air which is used for combustion. As an example of the economy which may be obtained, we may take the case of a furnace in which the air entering in sufficient quantity to effect complete combustion of the gas is raised in temperature to 1000° C. It will then have had imparted to it about 35 p.ct. of the total heat units of combustion of the gas. The value of recuperation in practice may be illustrated by the following data, which relate to a specially designed gas-fired muffle furnace for firing vitreous enamelled goods:

Inside dimensions of muffle . .	63 in. by 30 in. by 21 in.
Temperature of air leaving recuperator and entering combustion chamber	350° C.
Temperature of flue gases leaving recuperator	375° C.
Approximate gas consumption to maintain a working temperature of 950° C.	3·65 therms per hour.

A similar furnace in every respect, but without recuperator, required approximately 20 p.ct. more gas.

A striking example of the value of the application of the Siemens principle of regeneration to a gas-fired furnace designed for the heat treatment of steel billets is the following: The furnace was a "Revergen" open-hearth oven, 4 ft. 6 in. by 3 ft. by 2 ft., and the test required that the oven should be brought to a predetermined temperature (820° C.) and loaded-up with cold billets; the whole being then brought back to the same temperature and being so maintained for one hour. The following results were obtained:

Gas consumption per ton of billets to raise charge to 820° C.	16·3 therms.
Gas consumption per ton of billets to maintain charge at 820° C. for one hour . .	4·28 therms.

As compared with the results of an identical test in the case of a furnace without regeneration, the following efficiencies were recorded:

Raising Charge to 820° C.

Furnace.	Consumption per Ton.
Without regeneration	31·36 therms.
With "	16·30 "

Maintaining Charge at 820° C. for One Hour.

Furnace.	Consumption per Ton.
Without regeneration	6·70 therms.
With "	4·28 "

Inclusive Calculation per Ton of Billets Heated.

Furnace.	Gas Consumption to Raise Charge to 820° C.	Gas Consumption to Maintain Charge at 820° C. for One Hour.	Total for Operation.
Without regeneration . .	31·36 therms	6·70 therms	38·06 therms
With " . .	16·30 "	4·28 "	20·58 "

In the matter of regeneration, an interesting development in America is the employment of steel tubes which are specially treated by a process known as "calorizing." It is claimed that the treated tubes are preserved for a very long period from the destructive effects of the hot waste gases. The "Calco" system would seem capable of wide application, and should be watched with interest by those concerned with the heating of industrial furnaces with town gas. Of course, we are faced with the problem of the increased capital outlay which the employment of a system of recuperation entails; but there is little question that such additional cost is amply justified in numerous instances. It must be said that the application of such a system has its limitations—for instance, it is generally of little value for intermittent furnace work, and for very small furnaces it is not to be recommended except where extremely high temperatures are required.

To sum up the factors which require detailed attention for efficient furnace design and construction, these are: Correct system of burning gas; proportion of air to combustible gases; external radiation; terminal temperature of flue gas; temperatures of combustion and process; radiation and heat absorption by furnace body; and methods, where practicable, of using waste heat, which is often carried away by hot furnace gases.

To instance the advantages which may be gained by a study of the best means to adopt in using gas for fuel, two typical examples may be cited.

The London County Council Tramway Department required the South Metropolitan Gas Company to investigate the matter of heating steel tram-wheel tyres, as it was thought that the gas-fired system in use was not of the best. Experiments at the Gas Company's Laboratory resulted in the application of an entirely new system, which reduced the consumption of gas from 0·70 therm to 0·20 therm per tyre. A section of the furnace is shown in fig. 1 and a photograph in fig. 2.

The following example is an instance where the improvement effected did not refer so much to reduction in fuel, but to the greatly enhanced quality of the product. A series of so-called drying cabinets, but which are really hot chambers used for hardening the paint on tin plates, were internally fired by gas by means of bar burners situated in the bottom of each cabinet.

FIG. 7.—A view of the Industrial Demonstration Laboratory of the South Metropolitan Gas Company for the purposes of investigating and demonstrating the suitability of gas for industrial heating, and for affording opportunities enabling potential customers to examine the possibilities of gas for meeting their individual requirements.

The fault with the system was unequal treatment of plates, owing to bad distribution of heat. The problem was investigated, and as a result the system shown in fig. 3 and illustrated in fig. 4 was adopted, by means of which uniform and regular heating is now assured.

A very simple and efficient method of furnace construction is shown in fig. 5. A furnace of this type is suitable for operations in which graded or stage heating is required. Fig. 6 is a photograph of a furnace of this description.

Numerous other examples might be recorded, but these must suffice to illustrate the necessity for giving detailed consideration to every problem where improvements are possible. In order that the campaign against the wasteful methods of using the nation's coal which are in operation to-day may be successfully waged, the gas industry must enlist the services of the right type of men to deal with it. Experience has shown the necessity for a fuel technology department, capable of dealing with the hundred-and-one heat treatment processes met with to-day. In numerous instances the South Metropolitan Gas Company have achieved success in this matter solely by experimental research in their laboratories, which has resulted in the elucidation and the correct principles of design and construction of gas-fired appliances. Finally, collaboration of the salesman, chemist, physicist, and the practical designer is essential to progress in the utilization of both coke and town gas in the industry.

I am indebted to Dr. Carpenter for permission to use the information and data contained in this paper. My thanks are also due to the staff of the Physical Laboratory for their assistance in its preparation.

Discussion.

The Chairman said they would all agree that the paper had covered a very wide field. Most of the statements made were actual facts which left no room for criticism. If gas was to be successfully employed as an industrial fuel, it was necessary to pay strict attention to the points indicated by Mr. Chandler—such as the reduction of losses due to radiation, conduction, and sensible heat in the waste gases from furnaces. These points, it must be confessed, had up till recently been honoured more in the breach than in the observance.

Mr. S. B. Chandler (Tottenham District Light, Heat, and Power Company) thanked the author for the valuable data contained in his paper, which would, he said, add lustre to the Transactions of their Association. Speaking as one who had a great deal to do with the industrial applications of gas, he would stress the importance of co-operation between, and co-ordination of, the technical and commercial staffs of gas undertakings. The day when the gas engineer undertook all branches of gas-works practice was past; and the necessity for employing specialists was now recognized.

Mr. W. L. Westbrook (North Middlesex Gas Company) asked the author for further details of the calorizing process, in particular the use of calorized steel for grill plates, &c. It was, of course, impossible to glean from books knowledge which actual experience with plant yielded.

Mr. W. T. Kenshole (Lea Bridge District Gas Company) said the Association were greatly indebted to Mr. Chandler for his excellent paper. Having developed the industrial load, it was most important to ensure a supply of gas of constant calorific value and composition and at a satisfactory and unvarying pressure. With regard to the preheating of the gases, was a limit imposed by the ability of the furnace lining to withstand very high temperatures?

Mr. A. Broadbent (Hon. Treasurer of the Association), referring to the utilization of coke for steam generation, said that two or three years ago Mr. Hugh Seabrook had given them a paper in which he pointed to the need for co-ordinating the gas and electricity industries. Had anything materialized in the meantime?

Mr. J. G. Joyce (Gas Light and Coke Company) asked what type of air and gas controller was used in the metal-melting furnaces illustrated in the paper.

Mr. Chandler, replying to the discussion, said that as a result of investigating the calorizing process, he was very favourably impressed by its possibilities. It was being used extensively and increasingly in America, and he thought there was a big future for it in this country. Several gas companies in and around London were being supplied with calorized gas grillers, which were giving every satisfaction.

At this stage Mr. Chandler exhibited some ordinary cast-iron and wrought-iron regenerator tubes which had been heated to 1000° C. for 16 hours. By contrast he showed a calorized tube which had been subjected to the same temperature for 96 hours. Whereas the latter was unaffected, the cast-iron and wrought-iron tubes had very considerably deteriorated.

He would mention that Messrs. Hadfield had brought out a new material in competition with nickel-chromium, which promised to be of great service to heating engineers. This new material had, without deteriorating, withstood a temperature of 1000° C. for 128 hours, and the same temperature in an open coke furnace for 36 hours. Nickel-chromium alloy withstood such conditions, but, generally speaking, its cost was too high for general use. The new material could be produced at a little over half the price, and calorized tubing cost much less than this. He was in entire agreement with Mr. Kenshole regarding the need for a constant quality and pressure of gas. The South Metropolitan Gas Company had always stressed this point. As to the temperature to which furnace linings could be subjected, there were materials available which were suitable for almost any temperature—certainly up to 1700° C. It was all a question of cost. Mr. Broadbent had referred to the use of coke for steam generation. After the war the London County Council generating station at Greenwich employed a mixture of small coal and coke breeze, burning this by the "Sandwich" system introduced by Mr. Nicol. This proved highly satisfactory. About 40,000 tons of coke breeze were used, and a saving of £8000 was effected as the result of a year's working. What could be done at a large station could be accomplished at the smaller ones. In reply to the question asked by Mr. Joyce, the controllers used were made by Messrs. James Keith and Blackman Co., Ltd.; and these had given every satisfaction. Indeed, their installation had enabled them to compete with foundry-coke costs. For a particular installation, the cost of coke was £513 for twelve months. After replacing by gas-fired furnaces, a saving of £83 was made during a similar period. His experience in South London had taught him that an important factor essential for the successful application of gas to industry was good service. Every gas-fired installation should be inspected periodically, to ensure the consumer's satisfaction. All consumers should be made to understand that the services of the gas undertakings were at their immediate disposal.

Mr. A. Tennant (Croydon Gas Company), in proposing a vote of thanks to Mr. Chandler, said that, in view of the attention which was being given—both generally and officially—to the questions of coal conservation and smoke abatement, the time was opportune for emphasizing the benefits accruing from the use of gas as an industrial fuel.

Mr. J. R. Gale (North Middlesex Gas Company) seconded the vote.

Mr. Leonard Lacey (Hon. Secretary) announced that the summer meeting of the Association had been postponed till June 20.

National Gas Council.—The seventh annual general meeting of the Council is to be held on Tuesday, May 26, at 11.30 a.m.

Wales and Monmouthshire Junior Gas Association.—The third annual general meeting of the Association will be held at Newport, Mon., on Saturday, May 2.

EVOLUTION OF THE VERTICAL RETORT.

Mr. Walter T. Dunn, before the Junior Institution of Engineers.

For a long time, in years gone by, Mr. Walter T. Dunn, M.Inst.Mech.E., occupied the position of Secretary of the Junior Institution of Engineers, of which he later on became Chairman; and last Friday evening he once more did good service to the members, by presenting to them a paper on "Vertical Retorts," which was crammed full of useful information.

Mr. Dunn, during nearly thirty years spent as Secretary of the Institution of Gas Engineers, has, of course, had unique opportunity for the assimilation of gas engineering information; and of his store, he gave unreservedly to his brethren of the "Juniors." To deal with his subject as thoroughly as the author had determined to do necessitated a very lengthy paper indeed; and it was illustrated by a profusion of models, lantern slides, and diagrams, for the loan of which due acknowledgment was made to the Vertical Gas Retort Syndicate, Sir Arthur Duckham, K.C.B., the Woodall-Duckham Company, West's Gas Improvement Company, Mr. Alexander Wilson, M.Inst.C.E., and Messrs. Robert Dempster & Sons. With the author, we entertain no doubt that his colleagues in the Junior Institution shared his admiration of the splendid progressive work of the gas engineer and gas plant manufacturer in the excellent vertical carbonizing systems which he described, but which are, after all, only a part of the complete story of gas engineering; and that they were in full agreement with his claim that in no other branch of engineering is a deeper knowledge of physics, chemistry, and pure civil engineering demanded—knowledge that implies the ability to "direct the great sources of power in Nature for the use and convenience of man." It should here be said that the value of the paper was greatly enhanced by a visit on the following day—which had been arranged by permission of Mr. Thomas Hardie, the Chief Engineer to the Gas Light and Coke Company—to the Fulham Gas-Works, to see a 7 million c.ft. a day Glover-West vertical retort installation at an interesting stage of its erection. Previously the Institution had visited the works of the Tottenham District Light, Heat, and Power Company, where a 6 million c.ft. a day Woodall-Duckham installation was inspected in operation.

The subject was divided chronologically, by description or by illustrations, into nine sections, according to the dates of the introduction of the various systems. The sections were: Scottish Shale Oil (William Young)—1868 and 1872; Settle-Padfield—June 2, 1902; Dessau Intermittent (Dr. Bueb)—July 7, 1902, and 1904; Woodall-Duckham—July 27, 1903; Young and Glover—Nov. 17, 1905; Glover-West—Oct. 4, 1906; Glasgow (Alex. Wilson)—1911; Dempster-Toogood—1912; and Dessau Intermittent Chamber Ovens—1916.

Scottish Shale Oil Retorts.

Mr. Dunn had been fortunate enough to have lent him for the purpose of illustrating the shale oil retorts copies of a set of five working drawings of the Pumpherston patent retort for the Commonwealth Oil Corporation, Ltd., of Mid-Calder, as well as copies of two drawings of Mr. William Young's plant which was in operation at the oil refinery under his supervision. In 1874, Mr. Andrew Scott, of Musselburgh, introduced a vertical gas retort system which comprised a setting of four cast-iron (afterwards firebrick) retorts, each of 12 cwt. coal capacity.* This form of retort was suitable for the carbonization of shales. Steam was admitted into the lower portion of the retort for the production of water gas.

Mr. W. R. Herring, at one time Chief Engineer to the Edinburgh Corporation Gas Department, invented a vertical gas retort setting which was based on the Pumpherston shale oil retort. It was described and illustrated in the "Journal" for Jan. 16, 1906. Drawings exhibited illustrating Young's patent improved retort bench were of interest from the fact that the design of the first installation of Glover-West retorts (erected at St. Helens) was planned with them in view. In 1828 John Brunton patented an intermittent system for the carbonization of coal in vertical retorts. They were filled with coal, and the gas was given off at the top. Rowan, in 1855, patented a system in which the coke was discharged into a water bosh and then raked out from it by hand.

Settle-Padfield.

The late Mr. William Padfield, when Engineer at the Exeter Gas-Works, and his Assistant the late Mr. Thomas Settle, did important work in experimenting with vertical retorts and developing the system which bears their names. Their retort was intermediate between a continuous and an intermittent system. Coal was fed continuously into the retort, but the coke was discharged by hand at intervals—the retort being kept about half empty. In its design, the retort commenced in a vertical plane, but turned off at an angle at the base, so that the coke was discharged through the side of the bench, and not at the bottom.

Dessau Intermittent.

This system of verticals was the outcome of several years' experimental work by Dr. J. Bueb; the first setting being erected at Dessau by the German Continental Gas Association. The system was introduced into England by the Vertical Gas Retort Syndicate, Ltd.; and there are notable examples of it at Sunderland, East Hull, and Melbourne (Australia). A setting may comprise various numbers of retorts, 4 or 5 metres long, arranged in rows of two or three. In the latter type three retorts are controlled by one operation. The producer is placed alongside the retorts, and the regenerative flues on either side. The coal is fed into a charging hopper; and a measured quantity, with a small amount of breeze, is dropped into the retort, and the lid closed. The coke discharging door at the bottom is opened by means of a lever; hydraulic power being employed for operating it.

Mr. Dru Drury (the Gas Engineer at Sunderland) states that the period of carbonization of the charge may be varied to suit differing conditions; but a twelve-hour charge, including two hours of gentle steaming, has been adopted there. At the gas-works at East Hull, under the direction of Mr. R. Nelson, there are five beds of eighteen retorts, each worked in two shifts of eight hours per 24 hours; there being two periods of four hours each during which the bench is left unattended.

Woodall-Duckham.

In the process of invention of the Woodall-Duckham system, said Mr. Dunn, the truly British qualities of pluck, patience, and perseverance were strikingly displayed. Mr. H. W. Woodall (now Lt.-Col. Woodall, C.I.E.), son of the late Sir Corbet Woodall, D.Sc., when Engineer at the Bournemouth Gas and Water Works, had as his Assistants Mr. (now Sir) Arthur Duckham and Mr. H. C. Head, M.Inst.C.E., who is at present Engineer to the Winchester Gas and Water Works; and this trio of young gas engineering enthusiasts worked persistently at Bournemouth on the difficult problem of carbonization in vertical retorts. Their experiences are fully recorded in a paper by Lt.-Col. Woodall which he read before the Institution of Gas Engineers in 1908. After trials with several experimental settings, it was arranged that Mr. Duckham should resign his position of Assistant Engineer to the Bournemouth Gas and Water Company, and devote all his time to the problem of continuous carbonization. Designs were prepared for new plant, and on inspecting these the Directors at Bournemouth decided to erect a bench comprising four settings, each of four retorts, at their Bourne Valley Works. About this time, Mr. Thomas Goulden, of the Gas Light and Coke Company, and Mr. Edward Allen, of the Liverpool United Gas Light Company, reported favourably on the system to their respective Boards; and both Companies decided to erect installations, each of two settings of four retorts. The plant at Bourne Valley was started-up in January, 1907.

In the Woodall-Duckham system there are three standard sizes of retorts, having throughputs of approximately 3, 5, and 7 tons of coal a day respectively. They are 25 to 26 ft. in length, and of rectangular tapered section; the three sizes varying in the dimensions of the major axis—the minor axis remaining the same in all cases. The taper in the length is not continuous from top to bottom. Most of the taper is confined to the upper 10 ft., where the maximum swelling of the coal takes place. Two-stage heating is effected, thus allowing of efficient zoning of the heats in accordance with the requirements of the various coals.

Among the slides shown were the Glasgow plant of 21 million c.ft. per diem (1356 tons of coal), the largest continuous vertical retort installation in the world; and the installation at Innerleithen of 130,000 c.ft. daily capacity (7 tons of coal), which can be worked at 3 tons a day, and is the smallest Woodall-Duckham installation in Great Britain.

Steam is admitted at the coke extractor, and is superheated in cooling the coke.

Young and Glover.

Mr. William Young, of Peebles, and Mr. Samuel Glover, Engineer to the St. Helens Corporation Gas Department, designed a vertical retort setting which was patented on Nov. 17, 1905. An illustration of it will be found in the "Journal" for June 19, 1906 (p. 758). It was founded, in constructional details, on the Scottish shale retorts; but the discharge of coke did not govern the coal feed. The retort was not filled; but it was intended to keep the coal at a constant level, the space above the charge forming a radiant heat chamber for the dissociation of the tarry vapours. The gas also passed through the coal-feeding hopper before leaving the retort. In 1909 Mr. Glover and the late Mr. John West departed from this system, and reverted to that of governing the coal feed by the rate of coke discharge.

Glover-West.

The first Glover-West installation at the St. Helens Gas-Works consisted of eight retorts, each 20 ft. 9 in. long, which were put into operation in 1908, and remained at work until 1915, when they were taken out and replaced by four retorts of a special design. In these eight original retorts a great many varieties of coal from all parts of the world were carbonized under test conditions. The setting embodied all the principles which are still the fundamental idea of the Glover-West vertical retort setting. The retorts were heated by producer gas

* "King's Treatise on Coal Gas," Vol. I., p. 235.

nsumed in horizontal chambers superimposed one above the her in the height of the retort, so enabling the temperature to e varied at will throughout the length of the retort. Incomig coal was heated by waste products circulated in the top ambers, and heat was transferred from the outgoing coke to e secondary air circulated in the bottom chambers.

The second installation consisted of sixteen retorts erected the Droylsden Works of the Manchester Corporation, to e order of the late Mr. J. G. Newbigging; and the results of vere tests were given in a paper on "The Scientific Carbonition of Coal," which Mr. Newbigging read before the Institution of Gas Engineers at their Glasgow meeting in 1911. n this case 2 ft. 3 in. was added to the length of the retort, and e shape was altered to an increasing but changing ellipse, hich began at the top with straight sides and semi-circular ds 30 in. by 10 in., finishing in an ellipse at the bottom 36 in. 22 in. This increased the capacity from the original 2 tons 2½ tons a day. The retorts remained, with minor repairs, operation from 1910 to 1921, when they were re-built, with rtain modifications. Mr. W. Buckley published the results the eleven years' working in a paper on "The Maintenance osts of Continuous Vertical Retorts," which he read in May, 923, before the Manchester District Institution of Gas Engiers.

Other installations followed rapidly, and some of those inolving modifications in one form or another were described Mr. Dunn, and illustrated by slides. By 1918 the experince with the Droylsden elliptical retort had become sufficiently ngthy and full to show that, not only was the elliptical shape rrect, but that it must be developed in a particular way. n ellipse which in the descent of the retort involved a rapid hange in the shape of the major sides gave rise to spaces left etween the charge and the retort wall, with consequent inonveniences. These were avoided by constructing the retort ith a constant curvature in the major sides; and the standard hape was fixed on the firm foundation of experience and estabshed fact. The new design was introduced simultaneously at afford and Montreal. The retort was 53 in. by 10 in. over e major and minor axes respectively at the top, and it ineased at a constant angle to 39 in. by 18½ in. over the length 21 ft.

The demand of the country for fuel oils during the war led r. John West to undertake at St. Helens experiments in eaming the charge, which has since become the generally lopted practice in the operation of continuous vertical retorts. o far as the results concerned the production of fuel oils, and e establishment of the practice of steaming, they were pubshed by Mr. West in a paper which he read in November, 917, before the Southern Association of Gas Engineers and anagers. The St. Helens Gas Committee were so far connced of the practicability of the 40 in. retort that it was lopted in the third vertical retort installation, consisting of retorts, with an estimated capacity of 2 million c.ft. of gas day, erected there in 1921.

In 1920, the "New Model" retort was patented. This was othing more than the 33 in. by 10 in. retort 21 ft. long exnded to 25 ft. by the addition of a so-called "steaming chamer" at the base. The function of this chamber was to prode a zone in which the hot coke would be available for the irpose of raising the temperature of the steam to that of dsociation before it reached the retort proper, thus securing the lvantages of steaming without deducting from the heat necesry for dry distillation in the retort itself. The immediate fect of this development was that the retort was proved to be pable of carbonizing 50 p.ct. more coal per day, and producg from 50 to 100 p.ct. more gas; and this increase of capaty was obtained at a trifling increase in first cost per retort. he economic effect was that the capital cost of the Glover-'est system per unit volume of gas produced was reduced to e pre-war level. The extension of the new principle to the in. retort was the most natural direction for the next and last ep in the development of the Glover-West vertical retort. hat this design of retort has proved satisfactory is shown by e fact that it has been adopted by the Gas Light and Coke ompany for their Nine Elms Installation.

Glasgow System.

The Glasgow system of continuous-intermittent—continuous regards production of gas, and intermittent in relation to e processes of drawing and charging—vertical retorts, the inention in 1911 of Mr. Alexander Wilson (then Chief Engineer id General Manager of the Glasgow Corporation Gas Department) was introduced specially to deal with the hard nonking Scotch coal used by that undertaking. Neither the inrmittent nor the continuous system appeared fully to meet he requirements of the situation. A trial setting of four retorts as in operation at the time of the 1911 meeting in Glasgow the Institution of Gas Engineers, during Mr. Wilson's presiency. Various improvements were afterwards made; the setng giving encouraging results from the commencement.

With this system no constantly moving machinery is required; and the coke is cooled in bottom cast-iron chambers, which are attached movable buckets for holding the water als. These buckets are actuated by a small hydraulic ram. he retorts are heated in a simple manner; the producer being carried to the top of the setting. Fuel gas and secondary air are admitted between each of the top sections of the retorts, in parallel streams, so that little mixing takes place in the top section. The mixing of the gas and air, with the consequent combustion, takes place in the second section; the temperatures becoming gradually reduced in the downward travel of the gases.

Results obtained from the trial setting justified the decision to erect at Glasgow a 4 to 5 million c.ft. per diem installation on the site of a 2 million c.ft. section of horizontal retorts which were worn out and required complete renewal.

Dessau Intermittent Vertical Chamber Ovens.

This system is a development of the former Dessau intermittent vertical retort, and its construction in this country is in the hands of the Woodall-Duckham Company. The capacity of a plant now in course of erection, and having 25 chambers at 2¼ tons per charge per chamber, will be 112½ tons a day. This should make about 7800 therms a day, equivalent to some 1¼ million c.ft. The advantages claimed for the intermittent vertical chamber oven are the high rate of therm production per square foot of ground area; steaming can be carried out to an extent which is not possible with the horizontal system; low labour costs; absence of machinery, since charging and discharging are performed by the force of gravity; bulk quenching, resulting in a low moisture content in the quenched coke; absence of heat from the space in the chambers, producing superior qualities of tar and ammonia, and a higher quality gas; fewer occasions as compared with horizontal retorts for discharging coke, and consequent reduction of attendant losses. As each chamber is entirely separate, neighbouring chambers are not affected when being charged or discharged. The intermittent vertical chamber has been successfully operated with all classes of coal. With the use of best silica material for the chamber walls, there can be no sticking of charges. The adoption of the big chamber is better from this point of view than the old type of small Dessau retorts.

In closing, Mr. Dunn emphasized the great importance of the waste-heat boiler in connection with vertical retort installations, and referred the members to the paper read in November, 1923, before the Southern Association of Gas Engineers and Managers, by Mr. J. S. Thorman (Engineer of the Stratford Station of the Gas Light and Coke Company), entitled "Waste Heat and Its Insulation from Glover-West Verticals and other Carbonizing Plant."

Appreciative Remarks.

At the conclusion of the paper—the reading of which had, from considerations of time, to be somewhat curtailed—a number of questions were asked, and numerous indeed were the expressions of gratitude to Mr. Dunn for the great trouble to which he had gone in its preparation, as well as of congratulation upon the excellent results of his work. The Chairman (Mr. Edgar) said that Mr. Dunn had always taken a keen interest in the Institution, and it was greatly owing to his efforts that it had attained its present strong position.

Those taking part in the discussion included Mr. Gardner, of the Wandsworth Gas Company; Dr. E. W. Smith, of the Woodall-Duckham Company; Mr. R. J. H. Sayers, of West's Gas Improvement Company; and Mr. George Evetts—who pointed out that the vertical retort permitted the force of gravity to be used, once the coal had been got into the first required position, and, in addition to this, the plant itself was remarkably flexible. He agreed with Mr. Gardner in his contention that the horizontal retort was "not dead yet."

Dr. Smith explained that the resuscitation of the intermittent system was to meet the case of some districts where there was a demand for much denser coke than was made in the continuous vertical retort. Such coke could be produced in the intermittent retort, and gas made from the installation at approximately the same price per therm as with the continuous retort. The author had dealt in a most tactful and delicate way with the various competitive systems. He advanced an earnest plea for co-ordination in dealing with the vital fuel problem of the country.

Mr. Sayers, adding his meed of praise to the author, remarked that the paper contained a very complete history of the development of the vertical retort. He enumerated the main advantages of vertical retorts, and pointed out that provision was made for regulating the throughput so as to meet the carbonizing requirements of different kinds of coal. Extensive investigation had shown that there should be no difficulty whatever in carbonizing any class of coals—including such as were supposed to be "sticky," like Durham coal. At a great many works on the Continent, Durham coal was carbonized both in Woodall-Duckham and Glover-West retorts; and he did not think that in any of these works they would care to revert to the horizontal system. In addition to their other advantages, vertical retorts made a strong appeal to gas engineers from a coal conservation point of view.

In his acknowledgment of the many kind things that had been said, Mr. Dunn assured the members that he would always be ready to do anything in his power to assist an organization so near to his heart as was the Junior Institution of Engineers.

THE AUCKLAND AND DEVONPORT (N.Z.) GAS-WORKS.

The following brief description is taken from the Presidential Address of Mr. James Lowe, M.Inst.C.E., at the First Annual Meeting of the Gas Institute of New Zealand, which was held in February.

Auckland Works.

Gas was first supplied from the present manufacturing station at Beaumont Street in April, 1904. Prior to that date the old works at Nelson Street (shortly afterwards closed) had been the scene of manufacturing operations, since the start of the Company. The total area of the present site is a little over 14 acres; and on it the whole of the manufacturing plant, with the exception of the gasholders, is accommodated.

There are two gasholder sites, one of $1\frac{3}{4}$ acres at Freemans Bay, close to the works, where there are two 2-lift holders of 500,000 and 1,000,000 c.ft. capacity respectively; and the other of $3\frac{1}{2}$ acres at Beresford Street, about three-quarters of a mile from the works, where there is one 3-lift holder of 2,300,000 c.ft. capacity, and room for another of considerably larger size.

The site of the manufacturing station at Beaumont Street was originally on the side of a hill; the frontage at Beaumont Street being at sea-level, and about one-half of the area being 60 to 70 ft. high. It was originally intended to excavate the whole of this area to the level of Beaumont Street, but this intention was changed at a later date; and the top of the cliff was set aside for purifiers and extensions to them, tar and liquor storage plant, station meters, sulphate, anhydrous ammonia, and tar plants, &c. The frontage to Beaumont Street has been excavated as a site for retort houses and No. 1 coal store, workshops, offices, coke yard, &c.; and the boiler house,

Inclined Portion of Rope-Driven Suspension Railway.

engine room, scrubbers, washers, and condensers have been placed on a bank 12 ft. above yard-level.

No. 2 coal store has been carved out of the cliff at its northern end. This store is 174 ft. broad by 240 ft. long. It is made in four sections, each of which is built above a tunnel 240 ft. long driven into the cliff at right angles to Beaumont Street. The tunnels have been built to contain conveyors; and a "Marcus" conveyor is at work in one of them. Each section of the coal store forms a hopper, and the coal gravitates through revolving drums from the store on to the conveyor. The revolving drums are mechanically driven, and their speed can be varied so that the mixture of coals delivered to the conveyor can be altered at will. The cliff is composed of a sedimentary rock called papa, with a 12 ft. overburden of clay; and as this rock disintegrates, or weathers, when exposed to air, the store had everywhere to be lined with concrete, and reinforced where necessary. The height of the store from the underside of the roof trusses to the top of the tunnels is 42 ft. The inclined floors are lined with concrete, 6 in. thick; and all the walls except the front wall, which has no support from the cliff, are 18 in. thick. Each section of the store will contain 4500 tons, or an average of 18,000 for the four sections, without trimming. If the top of the coal were trimmed level, this figure could be increased to 25,000 tons.

Rope-Driven Suspension Railway.

As the top of the store is about 60 ft. above yard-level, it was designed to be filled with coal by a Bleichert rope-driven suspension railway, with automatic coupling and uncoupling apparatus for the cars. The loading station is a pit in the yard, and the cars rise 68 ft. up an incline to the top of the store, and then travel round a track shaped like a gridiron, with both right and left-hand curves, and down the incline to the loading station. As the war supervened, it was not possible to make a contract with the Bleichert firm of Leipzig; and we had to design, construct, and erect the railway. Before doing this, inquiries were made from a number of British makers of coal conveying machinery; but none would undertake the work.

The ropeway has at present a total length of about 800 ft. Each car carries about one ton of coal, and the capacity of the ropeway with six ropeway cars is 75 tons per hour. When the number of cars is increased to twelve (the maximum), the capacity will be 150 tons per hour. The traction rope is of the best extra-tough cast steel, $\frac{1}{2}\frac{3}{8}$ in. in diameter, with a breaking strain of about 95 tons per sq. in. It is driven by a 40-H.P. motor. This is necessary for the starting torque, but when the track is evenly occupied by cars, only 20 to 25 H.P. is required. The rails in the loading pit are laid with a slight gradient, so that one man can easily push a loaded car. On entering the loading terminal, the empty cars uncouple automatically from the traction rope, and are pushed by a workman in front of the loading chutes. The loaded cars are then pushed to the exit, at which point they grip the traction rope automatically, and are carried up the incline and round the track over the coal store, finally returning down the incline to the loading pit. When the current is switched off, the mechanism is prevented from moving by means of a solenoid brake on the driving shaft of the motor.

No. 1 coal store alongside the horizontal retort house is 250 ft. long by 70 ft. broad, with walls 30 ft. high. Its capacity is about 13,000 tons of coal, and it is filled by a gravity-bucket conveyor of a capacity of 50 tons per hour. Coal comes into the works in steel hopper wagons of 10 to 12 tons capacity running on the Company's street railway along Beaumont Street from the Western Wharf. Larger wagons cannot be

Water Gas Plant at Auckland.

used, since the small radius of the curves (68 ft.) limits the length of the wheel base to 6 ft. 6 in. Coke-fired locomotives supply the motive power for this railway.

Carbonizing Plant at Auckland.

The present carbonizing plant at the Auckland Works consists of 23 beds each containing nine horizontal retorts 24 in. by 16 in., 20 ft. long, and seven beds each of eighteen intermittent vertical retorts 13 ft. long. The horizontal retorts are charged by De Brouwer charging and discharging machines, and the coke is removed to the yard by a De Brouwer hot coke conveyor. Sixteen of the horizontal retort beds were originally built as settings of eight's. They were later rebuilt as nine's when opportunity offered, and additional beds of nine's up to the number of 23 were built. The house is now in process of conversion to settings of twelve's. This means that the arches have to be raised 2 ft., and the stoking machinery has also to be raised.

The hot coke conveyor will be discarded, and the telpher track, which will replace the conveyor, is already in position outside the retort house.

Water Gas Plant.

Three water gas plants are in continuous use. Two of these have been installed in conjunction with the horizontal retort house, and one in conjunction with the verticals. They are automatic in action, and the blow gases are utilized to heat the coal gas retorts. The hot water gas is passed through the vertical retorts; but, when used in conjunction with horizontals,

is passed, after being partially cooled, directly into the foul main.

Purifiers.

The purifiers are all of the water-lute type. There are twelve altogether; the last set of four boxes being built in 1913 on the top of the cliff. The boxes of this set are 27 ft. wide by 8 ft. long by 6 ft. deep, and are built two in a piece on a ferro-concrete framework, so that the bottoms of the boxes are 4 ft. above the ground. There is no permanent roof over these boxes, but two movable gantries running on rails and carrying a roof are provided. These gantries carry rope hoists capable of movement in vertical and horizontal directions, for lifting the oxide from ground-level and depositing it at any point in the boxes. Both the rope hoists and the gantries themselves are operated by hydraulic power.

Devonport Works.

The area of the site of the Devonport Gas-Works is about six acres. The land at the northern end of the site has been reclaimed from Shoal Bay. The land on the southern end is about 50 ft. above sea-level.

Travelling Gantry Carrying Hydraulic Hoist for Loading Purifiers with Oxide.

The coal store has been formed by excavation in this higher ground, the sides of the excavation having been trimmed to an angle of about 30°, so that the coal gravitates to a tunnel driven north and south under the coal store, where it is filled into tipping wagons which convey it to the coal breaker and elevator. The coal entering the works has to be carted, and is discharged by tipping carts or motor wagons from transverse bridges lying east and west across the store, and 21 ft. above the top of the tunnel.

The carbonizing plant consists of intermittent vertical retorts and water gas plant. The coke is removed from the retort house by hot coke tipping wagons which run under the retort bench, and are hauled up an incline by a wire rope, after being quenched outside the retort house. The breaking and screening plant and coke hoppers are at the upper end of the incline, and yard storage is obtained by tipping the wagons on the incline.

Manufacture of Firebricks and Retorts.

The manufacture of firebricks and retorts as a branch of the Company's business was begun about the year 1884. Fireclay of excellent quality is obtainable from the neighbourhood of Whangarei; and the bricks and retorts produced are not inferior to the best which can be imported.

View Inside Firebrick Works.

The works are up to date. Advantage has been taken of the slope of the ground to terrace the site, with the object of getting some help in the transport of material by gravitation. The drying sheds are provided with steam-heated floors, and hand labour is displaced by machinery where it has been found advantageous to do so. A semi-continuous gas-fired kiln of five chambers is at work; and when the output justifies it, this kiln can have additional chambers added to it, which will make it continuous. The life of the material in the horizontal retort settings is from seven to nine years.

VIEW OF THE DEVONPORT WORKS.

CHEMICAL TOPICS FROM CURRENT LITERATURE.

Notes from Recent Technical Publications.

By H. J. Hailstone, A.M.I.Chem.E.

Steam Raising.

An excellent aid to the control of combustion in steam boilers is referred to by C. E. Wade in an article on "Economy in Steam Raising" published in "Chemistry and Industry." In order to indicate the correct adjustment of air to fuel supply on boilers using coal, a simple attachment known as Carr's combustion indicator is fitted. This consists of a steam supply taken from the boiler through a coil in one of the flues, and in this way superheated. The steam then issues through a jet and induces a stream of the flue gases with it to a discharge pipe in front of the ashpit. Deficiency of air is immediately indicated by the presence of smoke at the discharge; and this may be rectified so that only a mere trace of smoke is perceptible.

Coke—and the Competition.

Reference to previous contributions under the heading "Chemical Topics" shows that the subject of coke has always been well borne in mind; and most readers need little reminding of the enormous dimensions to which the technical literature of this subject has grown during the last ten years. Sir Arthur Duckham's magnificent stimulus to further work, and the publication of really useful practical knowledge will, it is certain, do much towards clearing up many debatable points and establishing some definite and sound practical principles concerning the technique of economic production and handling of the grades of coke suited to the domestic and industrial requirements of this country. Every week brings fresh contributions to the study of the subject; and it is always difficult to select the most important items from a field of information having such intricate ramifications. One of the most notable of the recent contributions was Dr. Weyman's paper entitled "The Combustion of Coke in One Stage," now printed in the Transactions of the Society of Chemical Industry. This has already appeared in the "Journal" (Nov. 26, 1924, p. 570), and readers will have noted the very wide range of problems and phenomena dealt with. For a comprehensive bibliography of coke reactivity, ignition temperature, and structure the original article should be consulted. Another article of great interest on the same topic recently appeared in "Brennstoff-Chemie." Therein H. Bähr deals with some of the factors which determine the properties of coke. A knowledge of the moisture and ash content of the coal employed, together with the bitumen content and coking power, gives a basis for adjusting coking conditions. This basis may be further investigated by experimental tests at different temperatures and with different mixtures. The resulting coke may be examined for three significant properties—ignition temperature, reaction temperature, and reactivity—in one apparatus consisting of an electrically-heated quartz tube. On raising the temperature until carbon dioxide is formed in the current of air passed through the heated coke, the ignition point is recorded. Carbon dioxide is then passed through the tube, and further heat applied until carbon-monoxide may be detected in the gases; this point being the reaction temperature. The reactivity is obtained by still further heating the coke to 950° C. in a current of oxygen or carbon monoxide, when the proportion of carbon dioxide to carbon monoxide in the waste gases gives a measure of the reactivity. Valuable information can be obtained by investigations along such lines.

Iron and Steel Corrosion.

Mr. U. R. Evans has made a further contribution to this subject, and in a paper appearing in the Transactions of the Society of Chemical Industry deals especially with water-line corrosion—a matter of particular interest on the gas-works. Details are given of steels submitted to immersion tests in various dilute aqueous solutions; and, though useful information is yielded by such tests, it is pointed out that loss of weight of specimens treated in this way gives no correct indication of the damage done. The reason for this is due to the fact that, though equal amounts of corrosion may have taken place with two samples, in the one case the action may be local, and so result in pitting or even actual perforation, while in the other the damage may be general, and hence of much less significance so far as the life of an article may be concerned. The use of corrosion inhibitors is discussed at length.

Fractionation.

Interesting data regarding the working of fractionating columns having moving parts have been obtained by Messrs. Myers and Jones; and the report of their investigations has appeared in the Journal of the Chemical Society. The efficiency of fractionation, and also of gas washing, is, of course, largely dependant upon thorough contact between the vapours and liquids in the successive sections of the column; and the simplest mechanical aid to this end takes the form of a vertical revolving shaft with suitable plates or discs which serv to scatter the descending liquids as they pass from section t section. In separating the constituents of a mixture of benzen and toluene by fractional distillation, the influence of the spee of rotation of the shaft was very marked; increase of speed re sulting in more complete separation. This principle, whicl has been employed for years in certain types of vertical ga washers and ammonia stills in use in the gas industry, shoul find practical application on large-scale distillation plants, pro vided the probably greater initial cost and running expenses (a compared with those of the ordinary bubbling type of column are compensated by increased efficiencies and throughputs. O such a scale, however, it is likely that some device for sepa rating entrained spray will be found a necessary adjunct; an since the peripheral velocity of the disc is a determining factor comparatively low speeds of rotation could be employed.

Gas Analysis.

Two new reagents for the absorption of oxygen from mix tures of gases have been put forward. L. F. Fieser advises the use of a mixture of sodium anthraquinone sulphonate and sodium hyposulphite (see Journal of the American Chemical Society), and claims that this reagent works as quickly as the ordinary alkaline pyrogallol solutions in everyday use. Another reagent is due to Hofer and Wartenburg, who give, in "Zeitschrift für Angewandte Chemie," details of a method for determining oxygen. A solution of indigo carmine in sodium hyposulphite is employed, and a change of colour as compared with standards is noted after the passage of a measured flow of gas. Thus the oxygen content is arrived at after suitable corrections have been made.

"Zeitschrift für Physicalische Chemie" gives a method, due to L. Löwenstein, for determining hydrogen and methane. The gas containing these constituents is passed with an excess of oxygen through a combustion chamber, and the water formed (hence the hydrogen equivalent) is indicated by means of a hair hygrometer. Two new types of gas analysis apparatus designed by M. Dirken (Journal of Scientific Instruments) and H. D. Murray (Journal of the Chemical Society) have been noted. The former apparatus possesses a readily detachable absorption vessel in which the sample is shaken; and during this interval further samples may be dealt with in additional absorption vessels. Thus, when a large number of tests are required in a short time, this arrangement is particularly useful. Mr. Murray's apparatus is a portable one; and for this feature particular advantages are claimed. The burette has a three-way tap at the top; one limb leading to the sampling tube and the other to another three-way tap. This latter serves a receiving vessel containing mercury, and a special pipette. The gas sample is drawn into the burette containing water, and then passed through a jet into the absorbing solution in the pipette. Finally it is returned to the burette for re-measuring. Further absorptions are made in the receiving vessel, which may alternatively be used as an explosion vessel for determinations of hydrogen and methane.

Ammonia Estimation.

The determination of ammonia in its salts may be made by adopting the method outlined in "Zeitschrift für Analytische Chemie" by S. Lövgren. According to this method the solution of the salt is titrated with standard caustic soda, and thymol phthalein is used as indicator, giving a blue colour when the equivalent amount of alkali has been added. To obtain correct indication, one of the necessary precautions is that the solution contains at least 50 p.ct of alcohol; but the use of this may be dispensed with by making comparison tests.

Laboratory Apparatus.

"Chemistry and Industry" publishes a description of a laboratory wash-bottle designed by E. A. Roff. This enables a steady jet of liquid to be directed without the need for continuous blowing. In principle it is similar to the familiar type fitted with a bunsen valve on the inlet tube, and having a release tube controlled by the finger. The improvement consists of having a glass valve on the inlet tube, instead of a rubber one, which easily perishes. A further glass valve is fitted at the bottom of the outlet tube; and this serves to keep the jet always full of liquid, so preventing splashing when washing precipitates on filters, &c.

The mention of filters brings to mind the new sintered-glass filters manufactured in Jena and now being marketed in this country. These should rapidly find favour in gas-works laboratory operations. A recent illustrated list issued by Messrs. Baird and Tatlock gives full particulars of the various types of apparatus obtainable fitted with this filtering medium. By their use, ordinary filter-papers may be dispensed with in many quantitative and qualitative tests; some idea of the wide range and nature of their application being given in the descriptive list referred to.

Institute of Cost and Works Accountants.—The fourth annual costing conference will be held at the Hotel Great Central, Marylebone Road, London, N.W., on Friday, May 1.

NORTH BRITISH ASSOCIATION OF GAS MANAGERS.

Discussion on Maintenance.

(*Concluded from p.* 178.)

Mr. H. H. Gracie (Edinburgh) said it was imperative, if they were to retain the business they already possessed, that some form of free maintenance should be introduced. They were therefore indebted to those pioneers who had taken, and were taking, active steps to promote such an end. Some time ago a proposal originated with the Housing Committee in Edinburgh to the effect that the Gas Department should maintain the installations in good order, even to the extent of supplying mantles for the incandescent burners. The idea was that an extra charge should be made for the gas consumed by way of prepayment meter. The majority of the Gas Committee, however, did not favour the upkeep of mantles, though a suggestion was made to limit the number given free per annum, and it was also arranged to leave a spare mantle free in case of emergency. A modified scheme was prepared, under which four regular visits to each house per annum were to be made, when the various burners and apparatus were to be cleaned, adjusted, and put in full working order. Any other attention required was to be notified by a consumer by postcard or otherwise. Under this scheme, the extra charge for gas was comparatively small; but it did not receive the sanction of the Committee. The good results obtained in other towns might, however, cause his Committee to reconsider their decision on this important question. It seemed to him that attention should be directed to the steps being taken by a strong Committee of the National Gas Council to submit suitable suggestions to the Board of Trade for the examination of all piping, fittings, and appliances on the premises of consumers. The work which was now being carried out in many centres in connection with maintenance schemes was sure to disclose much valuable information. While they had not in Edinburgh a complete door-to-door visitation for the purposes of maintenance, still, they had a very complete system for following up and maintaining cooking, heating, and hot water appliances. One would expect that, with a well-planned scheme of this sort, the condition of the appliances would be so improved that attention would be required only at comparatively long intervals; and as a result, the general run of complaints would be reduced. He would like to ask those who had followed out this practice whether it was their experience that, after an appliance had been thoroughly overhauled and the defects remedied, it could safely be left without further care. The showrooms—or, as they were sometimes wisely called, the demonstration rooms—were now playing an important part in the maintenance campaign, by displaying under the best working conditions only the latest appliances. There was no doubt that they were promoting a good feeling with the plumbing and ironmongery trades; and their ideas of selling the goods to yield them a fair margin of profit was bringing people to the showrooms to make purchases. In this way it seemed to him they were ensuring that only the most reliable, as well as the most efficient, appliances were being fixed in the district. The ideal would be realized if they could get all the tradesmen to come to them for their supplies. If they could not do this, it would be only open to them to purchase and fit appliances which the Gas Department had tested and proved to be thoroughly reliable and economical in every way. The whole gas concern, which, in municipal areas, was the property of the community, would then be carried on in the best interests of the community. They must bring home to the gas consumer the fact that they were his best friends. They must show him that they were out to save him from the ill-suited and ill-designed fittings to be found in almost all districts.

Mr. David Vass (Perth) considered the subject was one they should seriously take to heart. In Perth they had been following somewhat on the lines suggested by Mr. Napier. They had a public showroom, and supplied from there the whole trade of the district. The Gas Department worked very harmoniously with the plumbing trade. Following out, however, the suggestions made by Mr. J. W. M'Lusky in the course of his Presidential Address to the Association last year, the question of maintenance had been tackled in Perth. A proposal was made that mantles should be provided over the whole city for a year at a fixed charge; but that idea did not "catch on," and he began to consider seriously if something on the lines of the Glasgow scheme would not be practicable in Perth. In the old days, they had a system of inspection of fittings; but due to economy, or some idea of that nature, the system of inspection was allowed to lapse. Later he suggested reviving that system of inspection of all appliances; arguing that the Gas Department were losing all over the town to electricity, and that the one way of successfully coping with the opposition was to have two or three fitters specially trained for the work to make a door-to-door canvass of the city. Experience had shown that if people were dissatisfied they were likely to continue dissatisfied so long as no official or fitter from the Gas Department visited them. He enumerated a few instances of pleased consumers, and maintained that these had resulted from the maintenance and inspection scheme which had been adopted in Perth. The scheme had only been in operation since Jan. 1, and so it was probably premature to say much on the question of cost. The expenditure in wages ran to something like one-third of a penny; and so far as he had gone, he was quite confident that the same staff as at present would be able to overtake the whole town and give two visits each year to all the districts. From his own experience, he thought Mr. M'Lusky's figures were quite well founded, and that all undertakings in the country ought to take the forward step of free maintenance. He had omitted to say that in Perth they started away with a scheme of renewing service pipes over the whole town; and this scheme had been in operation now for eighteen months. Originally it was intended to spread the work over five or six years; but they had since decided to concentrate on a complete renewal. The result was that every service in the town would be ample for years to come.

Industrial Consumers and Maintenance.

Dr. E. W. Smith (London) asked if the maintenance scheme in Glasgow covered industrial gas. If so, what happened if they found that for a particular operation the appliance used was not the right one? He knew it was a difficult point to settle. He came across an instance of this in the printing trade in London. Two years ago, probably about 5 p.ct. were on gas for metal melting; but now the remaining 95 p.ct. had adopted the idea, and were effecting a considerable saving. He supposed that with a proper maintenance system the gas undertaking would satisfy itself that the particular plant which was being used was the proper one to work with.

Mr. S. Milne (Aberdeen) felt the time was coming when they would have to face this question of free maintenance. In Aberdeen, since they put in gas radiators, they had made a periodical inspection of them; but up to the present they had not gone in for a properly-organized scheme. Mr. Vass had pursued the proper policy in tackling the service pipes. Proprietors of the older properties were slow to move in the matter, especially if it involved expenditure. Obviously the proper thing to do was for the gas industry to do the work itself. He had been struck with the figures given by Mr. M'Lusky. Certain inquiries that he (Mr. Milne) had made into this question of free maintenance had caused him to reckon that it would take about 2d. per 1000 c.ft. of gas used for domestic purposes only. Mr. Napier had rather suggested that the industrial consumers would have nothing to say, because they already had a special rate. This might be true; but he thought they should not stop at the domestic consumer. In Aberdeen they had lately introduced the practice of going over hotels, restaurants, and such places; and he was bound to admit that these quarterly inspections had been greatly appreciated. They charged a small fee, which was not grudged. He would like to ask Mr. M'Lusky how often particular premises would be visited in the course of a year; and he would also be glad to have an outline of the work done by the inspectors in Glasgow. Was each inspector confined to a particular district, and had he allocated to him a certain number of houses? Further, did the Glasgow Corporation supply gas brackets and pendants, and what was the position if, for instance, chandeliers were condemned? He noticed Mr. Napier advocated a service pipe laid at the expense of the gas supplier right up to the meter. Had Mr. Napier adopted this scheme in his own case?

Mr. J. J. Scott (Cowdenbeath) said in his district they had all along supplied a free service right to the meter. Not only so, but supplied free cookers. Indeed, they went even further than this, and actually provided internal fittings. During the past four years or so, they had added something like 1300 new consumers in whose houses they had supplied internal pipes, brackets, and fittings. Such a scheme as this appealed most strongly to him in that it made every householder a consumer. They charged a small additional sum per 1000 c.ft. to cover the cost of the internal piping system. They had trained their consumers to report all complaints in any shape or form. Indeed, they had educated them up to the practice of applying for information, assistance, and advice at the district gas office or showroom. Cowdenbeath was a mining locality, and not unnaturally they had experienced a good deal of trouble because of underground workings. The cost of the free maintenance scheme in Cowdenbeath did not exceed ¾d. per 1000 c.ft. He had been much impressed by the data given by Mr. M'Lusky, and would carefully examine the possibilities of changing-over to a definite periodical visitation scheme.

Mr. R. Sturrock (Ardrossan) explained that in his district they introduced a maintenance scheme eighteen months ago, and the cost worked out at 0·52d. per 1000 c.ft. Complaints had been considerably reduced.

Mr. A. Dow (Galashiels) could not give any figures relative to his maintenance scheme, because it was in its infancy. Inspectors had been instructed to make periodical visits, and the expectation was that each house would be visited at least once every three months. They did not propose to stop at supplying domestic fittings. In fact, in a preliminary sort of way, they had been giving attention to gas engines and industrial consumption generally. They had on the staff an engineer trained in gas engine work, and his services were always available to consumers. A record was kept of the consumption of gas among the power users; and if in any particular factory or workshop it appeared to be abnormal, an immediate visit was paid to the place, and inquiry made as to the reason. Should the gas engine require attention, a report was made as to the overhaul necessary; and if the manufacturer gave his sanction, the Gas Department were prepared to undertake the work. By this plan of campaign they had retained a good deal of valuable engine consumption in the district. Free maintenance ought not to stop at the domestic consumer. It could be adopted with success in industrial centres.

Piping Schedules.

Mr. John Wilson (Motherwell and Wishaw) said it had been stated that one of the first things in maintenance was the service pipes. He would include in maintenance, not only the service pipes, but the pipes in the houses themselves. What was the use of providing a proper service pipe, if the pipes in the houses were not in proper order? Had not the time come when the National Gas Council or some such body—the Scottish Section of the Council could do it—should schedule the sizes of service pipes for various houses and conditions? At the same time, a schedule could be drawn-up of the sizes of pipes for carcassing houses. The time had come when these things should be put down in black and white by a responsible body. This had been done already under the Gas Regulation Act with regard to the quality and pressure at which gas was supplied. It was only reasonable that house proprietors should be compelled to put in such pipes as were required by the schedule. Gas departments should have the same rights as water departments—to insist upon defects being put right. Mr. M'Lusky's figures, he believed, would prove effective in convincing gas companies and corporations that free maintenance paid its way. Perhaps Mr. M'Lusky would enlighten the meeting as to the type of individuals he employed as maintenance men. While speaking of reform, it might now be made clear that the town or burgh chamberlain's duty, in a municipal sense, should stop at the collection of the cash. The gas department

should control their own work right to the consumers, and be responsible for the reading of meters and the preparation of accounts.

Mr. David Fulton (Helensburgh) said they must first of all be satisfied that in the works they were producing absolutely pure gas. Then he was quite sure that the cost of maintenance would be negligible.

Replies by the Authors.

Mr. M'Lusky, replying to some of the points raised, remarked that Dr. Smith seemed to be concerned about industrial plant. In Glasgow there were a number of industrial plants; and it was the duty of the maintenance men to see that the regulation was right. If any point of difficulty arose, the maintenance staff could report to others who had charge of bigger industrial plants. The ordinary maintenance men were not expected to tackle a heavy industrial undertaking, except to make small adjustments and give advice. When they came to the end of May, he would have completed four financial years of the service pipe campaign, and in that time would have laid down a total of 30,000 pipes. From his own experience, he would say that, if they could guarantee to visit houses twice a year, it would make a great improvement. Eventually the maintenance might be extended to three times a year, but he would not go the length of saying that there should be four visits annually. As a matter of fact, twice a year to begin with would probably give satisfaction. In Glasgow they had sectional depôts and centres; and the system on which they operated was that one inspector had charge of 10,000 consumers. The ultimate scheme was to be ten inspectors, with forty men each. At the moment they were now running with 215 men—consisting of 184 actual house-to-house maintenance men, 9 staff repairers, 11 inspectors, 2 storekeepers in the depôts, 8 clerks on the general clerical work, and 1 controlling superintendent. The meter inspectors in Glasgow were clerks. Their duty was to read the meter and book the record. On the other hand, the maintenance staff was drawn from plumbers and gasfitters—men who had gone through a special test and training for work of this kind. In the selection of these men, regard must be had to their appearance and general demeanour. Men of the type required were not very plentiful. There were plumbers and gasfitters who would be useless for maintenance work. In regard to the apportionment of the cost of the Glasgow maintenance scheme, the principle followed was to calculate the charges on the total consumption of the city. The viewpoint they adopted was that everybody in Glasgow must pay for the maintenance scheme. He did not see how the allocation could be made in any other way. His costs had come down automatically, because they had done the worst parts, and were now passing into better property. The cost would remain, he should say, at ½d. He did not think it would be possible to bring it below this.

Mr. Napier said it appeared to him that the gas undertaking in the future must include, not only the manufacturing works and the distribution system, but all appliances used by consumers. Town councils, in the matter of laying-out new roadways and pavements, called upon the proprietor to meet the first cost. Afterwards the local authority took over these roadways and pavements and maintained them. This was done in the interests of the community. Gas supply also was a communal necessity, and he saw no objection to the local authority obtaining powers for the gasfitting of houses to be carried out to their approved specification. The initial expenses would be met by the proprietor, and afterwards by the gas department. This would strengthen very much the efficiency of gas supply. He put forward the suggestion as a practical one for the future. He looked upon it as a method of making certain that the gas industry would be put on a standard basis. As to Mr. Milne's question relative to service pipes, he felt that the proprietor should pay for that portion of piping laid on private ground. As indicated in the paper, he advocated that the work of maintenance should be subsequently carried on by the gas department. So far as Alloa was concerned, they had not carried out any such scheme in a wholehearted manner; but he had ventured to put the proposition forward as one worthy of consideration and acceptance by the officials of gas undertakings. Personally he hoped that the early future would see such a change in the affairs of gas supply as he had endeavoured to outline in his paper.

"B.C.G.A." North Wales and Cheshire District Conference.—Under the Presidency of Sir John M. Frost (Chairman of the Chester United Gas Company), a British Commercial Gas Association District Conference is to take place next Wednesday (April 29), in the Assembly Rooms, Newgate Street, Chester. The Mayor (Alderman David Lythall Hewitt, J.P.) will welcome the delegates; and there will be luncheon at the Grosvenor Hotel, and a visit after tea to a local gas exhibition. For the business sessions there will be an address by Mr. W. M. Mason, and papers by Mr. Owen Evans (Engineer and Manager to the Wrexham Gas Company), Mr. D. Rennet, M.B.E., M.D., D.P.H. (Medical Officer of Health to the City and County Borough of Chester), and Mr. Harold Hartley, D.Sc.

Tar Plants.—A "T.I.C." (lead) tar dehydrating plant supplied by the Woodall-Duckham Vertical Retort and Oven Construction Company, Ltd., has just been put into operation at the works of the March Gas Company, and is, we understand, working very satisfactorily. Orders have also been received by the Woodall-Duckham Company for bitumen and tar mixing plants from the City and Royal Borough of Dunfermline Gas Department, the Gas Department of the Alloa Town Council, and the Dundee Corporation Gas Department. The production of Road Board tar and bitumen tar mixtures by the gas undertakings of Scotland is being taken up with a considerable amount of enthusiasm, as the profits to be gained in the production of such materials by the gas undertakings themselves are considerably greater than those obtainable from the sale of crude tar.

GASHOLDERS: THE USELESS TOP LIFTS.

By Norton H. Humphrys.

The subject of storage capacity as compared with the output of gas, though prominent in the early days of our industry, is now rarely heard of. The output of gas has tended to spread evenly over 18 hours out of the 24, thus diminishing the degree of variation in the gasholder contents. The difference between maxima and minima, once over 50 p.ct. of the daily output, is now a mere trifle, perhaps not exceeding 10 p.ct.

Night work tends to increase, even in small towns; and frequently the consumption keeps step closely with the make, with the exception of a slight gain between midnight and 6 a.m. Accumulated experience is such that a temporary stoppage of the make, due to obstruction or other trouble at some point between the retorts and the gasholders, is practically unknown to the younger generation of gas engineers. Modern manufacturing plant is more extensive in variety, more reliable, and more elastic as regards rate of production of gas, than the 9 ft. horizontal retort which at one time was exclusively used. The continuous vertical retort and the cupola type generator enable the production to be kept nearer in line with the output. This state of things is a great advance on the time when the bulk of the consumption came between dusk and 11 p.m., and troubles due to pitch, naphthalene, and frost were part of the regular winter experiences—to say nothing of fog and November afternoons. From motives of economy in first cost, the manufacturing and purifying plant at the smaller class of works then consisted to a large extent of cast-off plant from the larger—often antiquated and inefficient in pattern, or as much a misfit as "father's old clothes."

Hence the remarkable fact that the obsolescence of about half the storage capacity, due to its not being equal to the pressure demands at the governor outlet, has been accepted with indifference. In order to comply with the pressure clauses included in the Gas Regulation Act, 1920, not less than 40-10ths is needed; but the usual top or single lift pressure is in the neighbourhood of 30-10ths. Sometimes boosters are put down with the view of meeting this defect; but the majority have not experienced any inconvenience, and have scarcely noticed the difference. The established rule of storage capacity—*i.e.*, total holder delivery content equal to 24 hours' maximum output of gas—was perfectly sound when applied to the conditions under which it originated, but is quite out of tune with modern requirements. Many gas-works have 100 p.ct. total holder content in accordance with this rule, but only 50 p.ct. of available storage capacity that can be distributed under at least 40-10ths pressure.

A fair representation of the average state of affairs at a gas-works supplying 100 to 125 million c.ft. of gas per annum is three holders, respective capacities 100,000, 200,000, and 400,000 c.ft.—a total of 700,000 c.ft. of gas—approximating to the above rule. These were in every respect efficient up to within the last twenty years or so. As late as 1895, in the course of a paper read before the Incorporated Gas Institute, entitled "Unaccounted-for Gas," Mr. D. Irving accurately voiced the current opinions among gas engineers by the statement that, if the district requirements could not be met with 18-10ths pressure at the governor outlet, enlargements of some of the mains should be considered. At that date, single-lift holders were more in evidence, and took a large share in the work of distribution; but to-day we shall not be far wrong in stating that the bulk of the work falls on multiple-lift holders. All subsequent enlargements or additions have been supplied with not less than two lifts; but in the above example only 300,000 out of 700,000 c.ft. of gas is available at full pressure.

At first sight one might conclude that top or single lifts can be used for 8 or 10 hours out of the 24. Stated in terms of hours, this is 33 to 40 p.ct. of the whole; but measured by the proper standard—thousands of cubic feet of gas—the proportion is nearer 4 p.ct. A more important difficulty is that the top lift takes precedence of the lower ones. They cannot be brought into active service unless the top lift is full. If the lower lifts could be worked independently, the position would be different. Unless the make does, or can be made to, outstrip the output, which is very improbable, the effect of starting (say) at 6 a.m. with the top lift half-empty will be a deficient supply until the top lift is again clear above water, which may not be possible until after the following midnight. Consequently many multiple-lift holders in use to-day have not had the first cup under water for months, and perhaps years. Yet no deviation is noticeable from the beaten track, and holders are being designed and erected on the old lines of a pressure of about 30-10ths off the first, and an additional 20-10ths as each succeeding lift cups. So far from a reduction towards the 1895 18-10ths, distribution pressures are being increased to such an extent that before long the second lift may be as inefficient as the first is at present. It is difficult to see where the engineer would be prejudiced, if his 700,000 c.ft. storage were replaced by 300,000 c.ft. under not less than 50-10ths pressure.

An example of the possibility of working efficiently with a small storage factor is furnished by an 80 million c.ft. gas-

works. The holder capacity (total) was ample, but chiefly concentrated in one 90 ft. double lift; the only addition being a 60 ft. double lift, the lower half of which represented less than 10 p.c. of the 24-hour output. The tank of the large holder leaked badly, and during twenty years the amount expended in pumping approached the original cost of the holder. Two successive managers held that the loss was unavoidable, as the holder could not be put out of action for a time sufficient to repair the tank without practically shutting-down the works. A third manager thought he could tackle the problem, although he had only old pattern 9-ft. ⏢ section retorts in the retort house; and he succeeded in maintaining an efficient service for six weeks with the large holder out of action. No specific complaint was received at the rental office, and outside the works there was no knowledge of any special matter in progress. The carbonizing account for the year showed no extraordinary increase.

There is no reason to suppose that this experience is unique; and doubtless similar examples might be quoted in proof of the fact that an efficient supply can be maintained on a storage capacity much less than 50 p.c. of the 24-hour output. This means that the cost of gasholders, the effect of which on the selling price of gas has been a matter of frequent comment, can be substantially reduced, not in the same proportion per 1000 c.ft. capacity, but to a degree sufficient to exercise important effects on the selling price of gas by reducing the capital outlay per million c.ft. of gas made per annum. Smaller holders mean not only lower first cost, but reduced annual expenditure for maintenance and upkeep.

That useless top lift should therefore be abolished, if it cannot be brought into useful service, by some system of loading. If of no use, it certainly is no ornament, and sometimes an objection to neighbouring residents. A time has arrived when the whole question of storage, the safe or necessary working margin, and methods of construction, especially in reference to pressure capabilities, might be fully examined. Some years ago it was the custom to enlarge on the advantages of a 24-hour storage; but with the levelling-down of the demand towards one even hourly rate on the one hand and increased elasticity of manufacturing plant on the other, the need for such provision is steadily disappearing. The suggestion that high-pressure reservoirs might efficiently replace the bulky and costly gasholder is not so absurd as it seems at first sight. Perhaps some daring engineer will bring out a scheme for dispensing with storage by methods of adjusting the make to fit the demand.

REGENERATION OF COMBUSTION GASES.

[A Communication from the Karlsruhe Gas Institute, "Das Gas- und Wasserfach," Feb. 7, 1925.]

The proposal has recently recurred that a proportion of the combustion gases in producer practice might be withdrawn as they enter the recuperator, and that, instead of steam, gases containing carbon dioxide should be introduced with the combustion air under the producer grate. It is suggested that a considerable economy in fuel can be effected in this way. As this proposal is continually coming up from one quarter or another, the Gas Institute decided to probe it thoroughly once and for all, and to clear up the facts.

Let it be assumed first that half of the combustion gases are withdrawn, that is, 1 cub.m. out of 2 cub.m. of waste gases, and that this is returned under the grate together with 1 cub.m. of air; then the process is as follows:

In the combustion gas there are about 4 cub.m. N_2 to 1 cub.m. CO_2. If this CO_2 is used to take up carbon from the solid fuel, then 0·536 kg. of carbon can be gasified per cub.m. CO_2, and 2 cub.m. CO formed.

$$C + CO_2 + 4\,N_2 = 2\,CO + 4\,N_2 - 1731 \text{ calories.}$$

There are, therefore,

Taken from the producer	− 1731 calories
Developed in the settings	+ 6068 ,,
	4337 calories

The heat developed in 1 cub.m. CO_2 is thus passed from the producer to the settings, with the formation of 10 cub.m. of waste gas (2 cub.m. CO_2 + 8 cub.m. N_2). If, instead, the producer temperature is lowered in the usual way by the introduction of steam, the reaction, again theoretically, is

$$C + H_2O = CO + H_2 - 1267 \text{ calories.}$$

To produce the same cooling effect in the producer, however, the decomposition of $\frac{1731}{1267} = 1{\cdot}37$ cub.m. of steam can be assumed.

$$1{\cdot}37 \times [(CO + H_2) + O_2 + 4\,N_2] = 1{\cdot}37 \times [CO_2 + H_2O + 4\,N_2 + 3034 \text{ cal.} + 2570 \text{ cal.}]$$

Therefore there are developed in the settings

$$1{\cdot}37 \times (3034 + 2570) \text{ cal.} = 7677 \text{ cal.}$$

with the formation of combustion gas

$$1{\cdot}37\,CO_2 + 1{\cdot}37\,H_2O + 4 \times 1{\cdot}37\,N_2,$$

or a total of 8·22 cub.m. waste gas. For 1000 cal., therefore, which are withdrawn from the producer, there are developed in the oven

By waste-gas regeneration, 3500 cal. with 10 cub.m. combustion products.
By steam decomposition, 4430 cal. with 8·22 cub.m. combustion products.

From which it appears there is no advantage in the regeneration process, but rather the contrary.

It is, however, claimed that the method effects a saving of 10 to 15 p.c. of fuel in the grate, corresponding to the heat which is brought back under the producer in the waste gas—and this without any change in the final quantity of waste gas and its heat content. The whole cycle may, therefore, be followed out mathematically.

Of 2 cub.m. of waste gas, assume that one-third is withdrawn and returned to the producer together with 1 cub.m. of air.

1 cub.m. air + 0·66 cub.m. waste gas	
0·2 × 0·66 CO_2	= 0·132 CO_2
0·8 × 0·66 N_2	= 0·528 N_2
0·8 × 1 N_2	= 0·800 N_2
0·2 × 1 O_2	= 0·200 O_2
1·660 producer air.	

Heat contents of producer air (waste gas at 1000° C.)

0·132 × 1000 × 0·511	= 67·5
0·528 × 1000 × 0·332	= 175·3
1000 × 20 × 0·312	= 6·2
	249·0 cal.

Heat changes in producer

0·132 (CO_2 + C = 2 CO) × (− 1731)	= − 228 cal.
0·1 (2 C + O_2 = 2 CO) × (+ 1303)	= + 260 ,,
0·1 (O_2 + C = CO_2) × (+ 4337)	= + 434 ,,
	466 cal.

At the outlet of the producer there are therefore available

$$249 + 466 \text{ cal.} = 715 \text{ cal.}$$

Composition of the producer gas

0·264 cub.m.	CO	24·5 p.c.	CO
0·2 ,,	CO		
0·1 ,,	CO_2	5·3 ,,	CO_2
1·328 ,,	N_2	70·2 ,,	N_2
1·892		100·0	

Theoretical temperature of the producer gas

$$\frac{715}{0{\cdot}1 \times 0{\cdot}514 + 1{\cdot}792 \times 0{\cdot}333} = 1100° \text{ C.}$$

Combustion of the Producer Gas

Producer Gas.	Air Required.		Combustion Products.	
	O_2	N_2	CO_2	N_2
0·1 CO_2	..	..	0·1	..
0·464 CO	0·232	0·928	0·464	0·928
1·328 N_2	..	..	..	1·328
1·892	..	..	0·564	2·256
	1·160 air.		2·820 waste gas.	

The result, therefore, is 2·82 cub.m. of waste gas instead of 2·0 cub.m. Of this, 0·66 cub.m. would be introduced under the producer, and the remainder, 2·14 cub.m., will be required to preheat 1·16 cub.m. of air.

There is available for the oven

1. The heat of the producer gas	715 cal.
2. The combustion heat 0·464 × 3031	= 1410 ,,
3. The heat of the combustion air (900° C.)	
1·16 × 900 × 0·33	= 345 ,,
	2470 cal.

Extreme temperature of the combustion

$$\frac{2470}{0{\cdot}564 \times 0{\cdot}562 + 2{\cdot}256 \times 0{\cdot}358} = 2200° \text{ C.}$$

Heat content of waste gases at 1000° C.

0·564 × 0·511 × 1000	= 288 cal.
2·256 × 0·332 × 1000	= 726 ,,
	1014 cal.

The heat available for the settings is, therefore,

$$2470 - 1014 = 1456 \text{ cal.}$$

With this regeneration of one-third of the waste gases, the expenditure of carbon for the heat production may be calculated as follows. In the producer gas there are 0·564 cub.m. of gases containing carbon. The quantity of waste gas used introduces 0·132 cub.m., so that there are produced 0·432 cub.m., and 0·432 × 0·535 = 0·232 kg. of carbon, which is, therefore, the quantity required for 1456 cal. in the combustion chamber. This, with a calorific value for the carbon of 8100 cal., represents 0·232 × 8100 = 1880 cal.

For 1000 cal. in the combustion chamber, therefore, 1290 cal. in the coke are consumed.

With this must now be compared the conditions when the

lowering of the producer temperature is effected by decomposition of steam instead of waste gas.

PRODUCER GAS WITH STEAM DECOMPOSITION.

An equal total calorific value of the producer gas must be assumed. In the previous example, 1·892 cub.m. contained 0·464 cub.m. of CO, or, with the regeneration of the waste gases, 1410 cal. Taking a water gas of the following composition

CO_2, 5 p.ct.			
CO, 28 ,,	. . . . .	0·28 × 3034 =	850 cal.
H_2, 10 ,,	. . . . .	0·10 × 2570 =	257 ,,
N_2 57 ,,			

the calorific value is 1107 cal. per cub.m.

The composition of the assumed producer gas is correct, since for 57 volumes of N_2 there are 14 volumes of O_2. Of these, 5 volumes are used to form CO_2, leaving 9 which may form 18 CO. There remain 10 CO, which, together with 10 H_2, have been produced by the reaction

$$C + H_2O = CO + H_2.$$

In order that the same calorific value as before may be available with this producer gas of 1107 cal. per cub.m.—*i.e.*, 1400 cal.—1·28 cub.m. of semi water gas must be produced, thus

0·064 cub.m.	CO_2
0·358 ,,	CO
0·128 ,,	H_2
0·730 ,,	N_2
1·280 cub.m.	

the formation of which produces

0·064 ($C + O_2 = CO_2 + 4337$ cal.)	= + 278 cal.
0·128 ($C + H_2O = CO + H_2 - 1267$ cal.)	= − 162 ,,
0·230 ($C + \frac{1}{2} O_2 = CO + 1303$ cal.)	= + 300 ,,
	+ 416 cal.

Heat contents of the steam (assuming 50 p.c.t. excess)

$$\frac{0·192}{0·8} \times 639·7 = 153·5 \text{ cal.},$$

or preheating the primary air to 400° C.

$$\frac{0·73 \times 100}{80} \times 0·320 \times 400 = (117 \text{ cal.})$$

So that at the outlet of the producer there are available

I. 416 + 153 = 569 cal. without preheating of air.
II. 416 + 153 + 117 = 686 cal. with preheating.

From which the temperature of the gas may be found as

I. $$\frac{569}{0·064 \times 0·524 + 0·128 \times 0·335 + 1·088 \times 0·338 + 0·064 \times 0·410} = 1230° \text{ C.}$$

II. $$\frac{686}{0·064 \times 0·530 + 0·128 \times 0·338 + 1·088 \times 0·341 + 0·064 \times 0·419} = 1420° \text{ C.}$$

Air and Combustion Products.

Producer Gas.	Air Required.		Combustion Products.		
	O_2.	N_2.	CO_2.	H_2O.	N_2.
CO_2 0·064 . . .	..	..	0·064	..	..
CO 0·358 . . .	0·179	..	0·358	..	..
H_2 0·128 . . .	0·064	..	..	0·128	0·730
N_2 0·730 . . .	..	0·972	..	0·064	0·972
	0·243	0·972	0·422	0·192	1·702
	1·215 cub.m. air		Waste gas, 2·316		

Heat contents of the combustion air at 900° C.

$$1·215 \times 0·329 \times 900 = 360 \text{ cal.}$$

Available for the oven

Heat of the producer gas	569 cal.
Combustion heat of the producer gas	1410 ,,
Heat of the combustion air	360 ,,
	2339 cal.

Extreme temperature without preheating the air

$$\frac{2339}{0·422 \times 0·508 + 0·192 \times 0·506 + 1·702 \times 0·362} = 2425° \text{ C.}$$

Extreme temperature with preheating the air

$$\frac{2456}{0·422 \times 0·570 + 0·192 \times 0·517 + 1·702 \times 0·364} = 2530° \text{ C.}$$

Heat contents of the combustion products at 1000° C.

0·422 × 0·511 × 1000 =	216 cal.
0·192 × 0·398 × 1000 =	76 ,,
1·702 × 0·332 × 1000 =	565 ,,
	857 cal.

Therefore there are available for the settings

2339 − 857 = 1482 cal. in case I.
2339 + 117 − 857 = 1599 cal. in case II.

The consumption of carbon is

$$0·422 \times 0·536 = 0·226 \text{ kg.}$$

Taking the calorific value at 8100 cal. per kg., this makes 1830 cal.

For 1000 cal. in the combustion chamber, therefore, there are required in case

I. 1230 cal. from the coke.
II. 1145 ,, ,, ,, ,,

Finally, the heat available in the waste gases must be estimated, as being employable up to 300° C. for steam raising. In all, taking the regeneration process first, there are 2·820 cub.m. of waste gas, of which 0·66 cub.m. is returned to the producer for regeneration. This leaves

2·160 cub.m.—0·432 cub.m. CO_2 and 1·730 cub.m. N_2.

Heat contents of this at 1000° C.

0·432 × 0·511 × 1000 =	221 cal.
1·730 × 0·332 × 1000 =	575 ,,
	796 cal.

At 300° C.

0·432 × 0·442 × 300 =	57 cal.
1·730 × 0·318 × 300 =	165 ,,
	222 cal.

Difference 796 − 222 = 574 cal.
For preheating air to 900° C. are required

$$900 \times 0·33 \times 1·16 = 314 \text{ cal.}$$

Leaving for steam raising 230 cal.

In the steaming process, the waste gases at 1000° C. contain

0·422 × 0·511 × 1000 =	216 cal.
0·192 × 0·398 × 1000 =	76 ,,
1·702 × 0·332 × 1000 =	565 ,,
	857 cal.

And at 300° C.

0·422 × 0·442 × 300 =	56 cal.
0·192 × 0·376 × 300 =	22 ,,
1·702 × 0·318 × 300 =	162 ,,
	240 cal.

Difference 857 − 240 = 617 cal.
For preheating air to 900° C. are required

$$1·215 \times 0·33 \times 900 = 360 \text{ cal.}$$

Total available for steam raising	257 cal.
Required for producer steam	153 ,,
Remaining for other steam raising	104 cal.

Summary.

	Heat Changes in the Producer.	Temp. of Gas Produced.	Available for Oven when Waste Gas at 1000° C.	Extreme Temperature of Combustion	Calorie Consumption of Coke per 1000 Cal. in Oven.	Free Available Waste Heat.
With waste-gas regeneration . .	+ 466	1100° C.	1456 cal.	2200°	1290	230
With ordinary steaming	+ 416	1230° C.	1482 ,,	2425°	1230	104
Do. with air preheating to 400° C. . .	..	1420° C.	1599 ,,	2530°	1145	..

Hence a detailed calculation of the heat processes involved in the regeneration of waste gases from a producer, as compared with ordinary steam injection, shows that no actual advantage is gained by the former method.

Preventing Corrosion.

The belief is expressed by Mr. R. B. Williams, writing in the "Gas Age-Record," that a remedy for wasteful and costly rust will be discovered, now that the problem is being attacked vigorously, and from many angles. He points out the economic importance of the problem to the gas industry, whose tremendous advancement will call into use a vastly increased amount of metallic surface. Even now, he says, metallurgists are learning to incorporate with iron a proportion of chromium; and when this proportion amounts to from 12 to 18 p.ct., a rustless iron results which is capable of taking a high polish, and is absolutely impregnable, not only to ordinary atmospheric influences, but even to such powerful corrosive elements as boiling sulphuric acid. Unfortunately, while chromium is not a rare element, it is sufficiently uncommon to make the cost of high-chromium steel prohibitive for ordinary usage. It has been found also that the incorporation of 0·5 p.ct. copper into iron will materially increase the resistance of the resultant metal to corrosive agents. Investigators are collecting more and more information on the causes of corrosion, and more and more material for the development of protective coatings or paints. One railroad, as an instance, has recently found that, by applying a certain protective covering, a marked decrease in corrosive tendency on rails results. Prof. Baker, of the University of Michigan, has discovered a method whereby steel can be electro-plated to a thickness of 0·001 in., instead of the usual 0·0001 in., at very little additional expense. This extra thickness of the nickel-plating affords a protective covering to the base metal that capably resists the test of the United States Bureau of Standards.

SCOTTISH JUNIOR GAS ASSOCIATION.

(EASTERN DISTRICT.)

Annual General Meeting.

The Annual Meeting of the Association was held on Saturday, April 11, in Edinburgh—Mr. R. L. Laing (Brechin), resident, in the chair.

The Hon. Secretary and Treasurer (Mr. E. L. Farquhar, Lower Largo) read the annual report of the Council for the 1st session, which stated that eight members had been added to the roll during the session; the total membership now being 17 ordinary members and 16 honorary members. The financial statement submitted showed that at the end of the year there was a credit balance of £50 4s. 11d.

On the motion of Mr. Laing, seconded by Mr. Gavin Galashiels), it was unanimously decided to devote a sum of money not exceeding £20 for the purpose of bringing the Association library up to date.

Mr. Farquhar intimated that he had decided not to stand for re-election, as he felt that his duties at Largo did not afford him sufficient leisure to devote to Association affairs.

The President remarked on the smoothness with which the business had been carried out during the two years Mr. Farquhar had been in office. The membership had been increased by 25, and the credit balance from £16 to £50.

The following office bearers were thereafter elected for the ensuing session :

President.—Mr. Alan Clark, Perth.
Vice-President.—Mr. H. A. Yuill, Dundee.
Hon. Secretary and Treasurer.—Mr. J. Scobie, Dunfermline.
Council.—Messrs. Carrie, Duffy, and Gavin.
Auditors.—Messrs. J. R. Moyes and J. M'Donald.

With a view to bringing the matter before members, a letter was read from the Institution of Gas Engineers intimating that a register was being prepared for the assistance of those members of the Institution out of employment.

Mr. Laing then delivered his

PRESIDENTIAL ADDRESS.

I have to thank you for the honour conferred upon me by electing me your President—an honour which I feel is considerably enhanced by the fact that during the current session our Association has attained its majority.

Education.

At present we are very much concerned with education; and I assume that we are agreed that this question in its broadest sense must be kept strictly in the foreground. The Institution of Gas Engineers have laid down a thorough and complete programme which coming gas engineers must follow. The question, however, which is really concerning many of us is how we are to study to the best advantage the subjects prescribed. I am in hearty agreement with the whole scheme, but am convinced that the lack of technical centres of education in the country generally and in this district in particular makes the further education of the gas engineer a problem rather difficult of solution. The average continuation classes in small burghs cannot reasonably be expected to provide facilities for such specialized instruction, where the enrolment must of necessity be small. Reliable guidance to the student with regard to the choice of subjects is a feature which is calculated to make for success. It may be argued that to men of our nationality the problem should present no insuperable difficulty; but until some scheme of suitable curriculum in our technical schools and classes is evolved, and a Director of Gas Education is appointed, there must be a considerable waste of time and energy on the part of the student. The greatest good for the greatest number cannot be obtained by prescribing a highly specialized scheme, and at the same time offering no suggestion as to the best means of carrying the scheme to a successful issue. I am glad to learn that an Advisory Committee for Scotland have been appointed; and I am sure they will do much to advance our claims for recognition in this direction, and put us on a better footing than originally arranged for. We could derive more benefit from an educative point of view from this Association if we maintained a more vigorous campaign of papers and discussions.

Carbonizing Plant at Brechin.

The installation is of the Woodall-Duckham type, and consists of two parallel benches of three retorts, regenerators, &c. The retorts are 25 ft. long, tapering from 3 ft. 4 in. by 8 in. to 2 ft. 4 in. by 20 in. at the bottom. The whole plant is capable of carbonizing 21 tons of coal a day—in six retorts of 3½ tons. This throughput can be altered, and it is possible to vary the make per mouthpiece considerably as occasion may demand. At present we have an average output of 62,000 c.ft. per retort per day. The average amount of coke produced is 13 cwt. per ton of coal carbonized; and of this amount, 30 p.ct. is generally required for the producer. This percentage varies according to the numbers of retorts working. On the average, the actual amount of coke for sale is just over 9 cwt., which, with the reduction of breeze, is reduced to nearly 8 cwt. Our net saleable coke figure is 5·9 cwt. This is coke actually leaving the works; the balance being used for steam raising. All coke is sieved through a 1-in. mesh before going to the producer, and is handled by the stokers themselves.

The coal is brought into the coal store by carts, is filled into hutches of 10 cwt. capacity, and elevated to the storage hoppers by a steam-driven lift. The hoppers are so arranged that they hold a three-day supply; and by keeping all the hoppers full, we are assured of a six-day supply. The stokers handle no coal. Two yardmen are engaged from 1½ to 2 hours every morning to fill the storage hoppers; and the lift is used afterwards for elevating coke.

Working Results.

Some figures regarding the work done by the plant may prove interesting. The retorts were put to work in July, 1920; and since then our annual make has risen from 41 to 47 millions. The cost of repairs and renewals to date has been £19, which figure includes the conversion of hydraulic to dry seals at the top of the retorts. The remainder is all for bottom ironwork, side bottom plates, and curved door plates which were eaten through by the action of the water and coke. This ironwork was renewed last summer. The brickwork of the retorts, beyond showing a slight picking of the joints round the bottom, is in excellent condition. The materials used were Glenboig. No bulging appears at any part. So far, three retorts only have been in action; and the following figures represent four years' working. The total amount of coal carbonized has been 107,400 tons—an average of 3571 tons per retort. For the same period, the gas (460 B.Th.U.) per ton of coal has been 16,405 c.ft., sulphate of ammonia 26·79 lbs., tar 18·86 gallons, and coke (net for sale) 5·5 cwt. We steam at 15 lbs. pressure; and the original steaming arrangement was altered to one of our own design. With the present system there is no trouble in disconnecting the superheater, and no danger in burning-out during scurfing operations. The present tubes have been doing duty for 2½ years, with no repairs. The retorts are run for twelve weeks without scurfing; and we are in favour of periods not exceeding this. Clean retorts promote steady working, regular coal feed, and consequently a straight line on the calorimeter record.

Indicators are fitted to each auxiliary coal hopper, which can be read at floor-level. There is then no excuse for short or extra coal feed. The attendant is able to watch the working of the retorts without having to climb to the top of the bench. I would certainly recommend this indicator system for small installations. It is not an expensive item, and certainly repays itself in better results and saving of labour. The producer has given us little trouble except with the accumulation of dust and very small breeze at the back wall. If this layer is not attended to, it becomes black and dead, and reduces the area of the producer to a considerable extent. This trouble has been largely overcome by introducing an additional firebar about 18 in. deep, two steps up, which enables the stoker to get right through to the back of the grate, and keep the whole fire always on the move. The producer is pricked-up every four hours, and clinkering is only done at long intervals, much depending on the class of coke in use. In working vertical retorts of the type and size with which I am acquainted, I would summarize the main features of good practice as follows :

(1) Scurf at regular intervals.
(2) Steady make per retort.
(3) Periodical attention to flues, regenerator, and producer.
(4) Ample chimney pull.
(5) Strict attention to exhauster vacuum and retort-house governor.
(6) Interest in the workmen directly connected with the retort house.

A comparison between the first and fourth year's working is interesting :

—	1920.	1924.
Gas manufactured	41,129,600 c.ft.	46,408,000 c.ft.
Coal carbonized	2,787 tons	2,665 tons
Gas made per ton of coal	14,757 c.ft.	17,413 c.ft.
Price of coal per 1000 c.ft. made	1s. 9·9d.	11·59d.
Labour	10·66d.	8·01d. (includes distribution, sulphate of ammonia, &c.)
Carbonizing costs only	5·01d.	3·24d.
Residuals realized	1s. 5·90d.	1s. 0·63d.
Coal per ton in works	46s. 9·6d.	31s. 11·1d.
Calorific value of gas	475 to 460	430 to 440
Price per 1000 c.ft.	6s. 8d.	4s. 7d.
Cost of repairs (per 1000 c.ft.)	..	·03d.

As will be observed, our present calorific value is given as 430 B.Th.U.; but in the absence of a total heat calorimeter, and running constantly with the Beasley recorder, I am not claiming this figure with absolute certainty. Two jet photometers are installed in the retort house—one in direct connection with the purifier outlet and placed in a convenient position in the retort house. The gas which is passing from the retort can thus be seen burning 30 to 40 minutes later at the photometer; and a change in calorific value can be immediately investigated. Gas of a steady calorific value is at all times our ideal; and with

attention to the points enumerated, and strict observance of retort house conditions, stokers themselves find an interest in keeping a straight line on the chart. Further to help to nullify any discrepancy in calorific value which may take place in the supply to the district, all the gas made is led into the largest holder, and fed back into the smaller as the consumption demands.

At the introduction of vertical retorts, with which in our case a reduction of the calorific value of the gas was made, it was necessary to survey the distribution system. The change-over was made at an opportune time—viz., the middle of June. We were thus enabled at first to give full attention to cooking apparatus, and gradually deal with the lighting and heating appliances as the load came on. We were aware that portions of the town mains were requiring attention; work was commenced immediately. For some time we were engaged laying new steel mains and extending and renewing services. Now, at the most distant point from the works, we are able to maintain ample pressure. We are in the fortunate position of having our works at the lowest part of the town, and have no difficulty, with a works pressure of 30-10ths, in providing a pressure of 2 in. at the consumers' meters 1½ miles from the works, when the heaviest load is on. We have laid over 5000 yards of steel main ranging in size from 1½ in. to 4 in. diameter.

As road construction has been everywhere carried out extensively in Brechin, we took the opportunity of examining and, if necessary, increasing services and mains. All steel mains are of the spigot and faucet type, with lead joints. Nothing smaller than ¾ in. service is laid. Most services are taken from the side of the main with heavy brass couplings; and in the case of a short service (anything up to 12 or 15 ft.) lead pipe is used. Where there is a long run, galvanized tube of steam quality is installed. This is excellent, for there is less corrosion. Our distribution system also includes seven miles of steel main supplying high-pressure gas to a neighbouring village. As this main runs for nearly a mile through part of the town, we have utilized it to a fair extent for supplying various large consumers in the town. We boost at 60 in. with a Bryan Donkin compressor, and all high-pressure regulators are by the same firm. The system works perfectly.

Strict investigation of meter inspectors' reports helps at all times. Cookers are loaned free provided a certain amount of gas is consumed per annum, and they can also be had on the hire-purchase system. Gas fires and radiators are all hire-purchase, but every encouragement in the way of price is given for an outright sale. There are 2630 consumers; the average consumption per consumer being 17,000 c.ft. for ordinary, and 15,000 c.ft. for prepayment, meters. Since 1914 the number of consumers has increased by 330, and the annual make has risen from 30 to 48 millions—and this despite a decrease in population of nearly 16 p.ct.

I would here make a slight reference with regard to competition with electricity, and relate briefly what has been happening during the last few years in our city.

Electricity at Brechin.

The electricity supply was originally under an Order of 1898, granted to the Burgh of Brechin; and in 1900 a deed of transfer approved by the Board of Trade transferred the Order to a private company. The Order of 1898 allowed a maximum price of 8d. per unit, with a minimum charge of 13s. 4d. per quarter. From 1900 until 1914 the price ranged about 6d. per unit; and it was not until 1919 that the maximum price of 8d. per unit came into force. Then in 1920, under the Temporary Increase of Charges Act, the Company were granted an Order to charge a maximum of 1s. per unit for lighting, and a minimum charge of 15s. during the winter quarters, and 10s. during the summer quarters. From 1900 until 1919 competition was keen; but it was not until four years after this minimum charge had been adopted that the Electricity Company were able to pay a dividend, when their profit rose from £600 to £2000. Naturally the increase in price, and especially the minimum charge, did not find favour. A public meeting of protest was called, and subsequently an inquiry was held by the Ministry of Transport. One consumer giving evidence at the inquiry said he had paid £2 for four summer quarters, and consumed 16 units, so that he was paying at the rate of 2s. 6d. per unit. All this controversy and dissatisfaction brought us many consumers; a goodly proportion of them being shopkeepers. We have been able to convince them that gas as an illuminant is equal to electricity. As regards costs, with electricity at 1s. 5d. per unit, the majority of new consumers have halved their previous lighting bill. That gas for cooking and heating holds the field, no one will dispute.

Mr. Clark proposed a vote of thanks to the President.

Mr. Laing thanked the Association for the way in which they had supported him during his term of office.

Thereafter the members joined their lady friends at tea, following which an enjoyable whist drive and dance completed a successful meeting.

"Journal" Index.—The index to the "Journal" for the past quarter—January-March—is given as a supplement to this issue.

POWER ALCOHOL.

Production from Tuber and Root Crops in Great Britain.

As a fuel, alcohol possesses many advantages, perhaps th chief of which is that it allows the use of high compressions, t to 200 lbs. per sq. in. On the other hand its volatility is lov and consequently it is necessary to add a more volatile "liver ing agent." It does not mix freely with petrol, so that th latter is in this respect ruled out of court. It is, howeve miscible with benzole in all proportions, and the resulting mi ture is a highly efficient fuel. Every day one hears of the nece sity for finding a substitute for imported petroleum product Benzole is as good as, if not better than, petrol as a moto fuel; but the supply is by no means equal to the demand. seems possible, therefore, that, if alcohol can be produce cheaply in Great Britain, the standard home-produced fuel the future may be a benzole-alcohol mixture.

Alcohol from Potatoes.

For several years before the war, Germany produced larg quantities of alcohol from potatoes specially cultivated for th purpose. The history of this German industry is comprehen sively given in "Power Alcohol," by G. W. Monier-Williams He points out that the success attained prior to the war wa due not so much to actual cheapness of production as to th effect of State subsidies. If we can draw conclusions fro continental experience, the cultivation of potatoes in Gre Britain, with the object of producing power alcohol, would de mand heavy subsidies, and would not, under present condition be economically practicable. It is significant that, before th war, 95 p.ct. of the alcohol produced in Germany was mad from potatoes, while in 1920-21 only about 15·5 p.ct. was s made.

Work of the Fuel Research Board.

The Department of Scientific and Industrial Research (Fue Research Board) have just published their Third Memorandu on "Fuel for Motor Transport," which is concerned with th production of power alcohol from tubers and root crops in Gre Britain. In this pamphlet (obtainable from H.M. Stationer Office, Adastral House, Kingsway, W.C. 2, price 9d. net) it i stated that the only possible raw materials which could b grown in Great Britain and Ireland for this purpose ar potatoes, mangolds, and Jerusalem artichokes. It is unlikel that potatoes could be grown at a price which would make i possible to obtain alcohol for use as an alternative to petrol a anything approaching its present price. Stated briefly, 1 to of potatoes produces 20 gallons of 95 p.ct. alcohol, so that ever £1 it costs to grow a ton of potatoes is equivalent to 1s. on gallon of alcohol for raw material. A possible way in whic alcohol might be produced for the purpose is suggeste —viz., co-operation between the potato grower and distiller, th erection of small distilleries in the centres of growing districts the combination of cattle rearing with potato cultivation so a to utilize the distillery residues for cattle feeding, and the us of the resulting manure on the land. The mangold possesse several advantages over the potato. It is an easier crop t grow, harvest, and store, and it is not so liable to disease an failure. Its carbohydrates, being in the form of sugar, simplif the manufacture of alcohol. It is, however, susceptible to in jury from frost, and cannot be grown in the north of Englan or in Scotland. The yield of 95 p.ct. alcohol per ton, calculate on the average sugar content, is about 8 gallons; so that ever £1 it costs to grow a ton of mangolds is equivalent to abou 2s. 8d. on a gallon of alcohol for raw material. The averag yield of mangolds per acre in Great Britain is, however, 1 tons, as against 5·7 tons of potatoes; and the price is abou £1 10s. for the former as against about £7 for the latter o the wholesale market. If potatoes were used, the cost pe gallon for the raw material would be 7s.; if mangolds, the cos would be 3s. 9d. The yields from Jerusalem artichokes var from 15 to 25 gallons of 95 p.ct. alcohol per ton.

Tempering Springs by Gas.

An account of the installation of a continuous-process ga oven for tempering the springs of automobile seats was give some little time ago in the pages of the "American Ga Journal." For these seats helical coil springs are turned ou in great quantities; but the wire used in the coils, after the have been formed, is too hard to be fitted in a seat, and to giv service, without the coils flattening, and so it becomes neces sary to resort to tempering. Immediately after being formed the coils are packed on perforated metal trays (each tray hold ing 40 lbs. to 50 lbs. of wire coils), and carried in a continuou line on gravity conveyors to the tempering oven, to which the are transferred. The oven temperature is maintained at 500 Fahr. Direct gas burners with blast tips, operating at 1 lb pressure developed by a Roots gas pump, are controlled auto matically by Robertshaw temperature controllers. With tw conveyors operating, the oven equipment accommodates 24 trays an hour, each holding 40 lbs. of coils, making a total o 9600 lbs. an hour delivered, or approximately 86,400 lbs. pe nine-hour day. The heat treating time is 15 minutes.

CORRESPONDENCE.

Government Subsidies.

Sir,—With reference to the possible subsidy by the Government to electricity undertakings, it would appear that the utmost vision has not been utilized. As the gas industry is the chief conservator of our coal supplies, would it not be better to subsidize this industry for the purpose of expanding its production of aniline dyes, and thus enable the gas undertakings of the country to engage chemists on research work with a view to our equal efficiency with Germany in regard to yes?

"Carboniferous."

April 17, 1925.

REGISTER OF PATENTS.

Regenerative Gas Furnaces.—No. 208,700

Huessener, K., of Pittsburgh.

No. 30,480; Dec. 4, 1923. Convention date, Dec. 21, 1922.

This invention relates to the regulation of combustion, and consists essentially in regulating apparatus wherein the air and gas are fed to the furnace through chambers connected to pressure-controlled mechanism. The latter regulates the supply of air and maintains the air and gas pressures inside the chambers at a constant ratio. A hand-controlled valve is provided in the air supply conduit between the air chamber and the furnace; this enabling the apparatus to be adjusted.

Gas-Fired Firetube Boiler.—No. 216,151.

Eickworth, R., of Dortmund.

No. 12,072; May 16, 1924. Convention date, May 16, 1923.

A single U-shaped firetube is used for heating the boiler; one of the two ends being provided at the front end of the boiler with a blade wheel burner, while the other end of the firetube is provided (also at the front end of the boiler) with a fan connected to the burner by gearing.

Coke Handling Plant.—No. 218,654.

Koppers Coke Oven Company, Ltd., of Sheffield.

No. 15,800; July 1, 1924. Convention date, July 5, 1923.

A method commonly adopted for handling coke from coke ovens consists in pushing the coke out of the oven into a car, then running this under a central quenching tower, and thence transporting the coke from the car to a screening plant by a conveyor. This invention relates to this system. In combination with an elevated storage bunker from which the screen can be fed is used an inclined chute below the bunker, delivering directly to the screen, so that the latter can be fed from the bunker or by the chute alternatively; the coke conveyor being arranged to deliver either to the inclined chute below the bunker, or to an inclined chute above the bunker. Under normal conditions the coke is delivered directly from the intermediate container to the bottom chute leading to the screen; but in the case of a stoppage at the screen, incoming coke is deflected to the bunker, whence it is delivered to the screen when convenient. Direct feed to the screen may proceed when the bunker is full.

Purification of Coke-Oven Gases.—No. 224,863.

L'Air Liquide Sté. Anyme pour l'Etude et l'Exploitation des Procédés Georges Claude, of Paris.

No. 18,793; Aug. 7, 1924. Convention date, Nov. 17, 1923.

By this process the carbon dioxide and sulphuretted hydrogen are removed from the gas by passing it through a column provided with Raschig rings through which an ammoniacal solution is circulated. This solution can afterwards be regenerated by passing it through a tower provided with plates in which it is subjected to a progressively increasing temperature sufficient to expel the carbon dioxide and sulphuretted hydrogen. Alternatively the solution may be distilled, and the ammonia evolved converted into sulphate.

Safety Cocks for Gas Burners.—No. 229,876.

Schar, F., of Schwechat, and Theumar, R., of Vienna.

No. 7182; March 20, 1924.

This invention relates to gas burners of the kind in which, as long as the burner is alight, the shutting-off member is retained in the open position by a flexible clamping device under the influence of the generated heat, but is automatically closed as soon as the burner is extinguished. According to this invention, a rod is arranged to move longitudinally between the burner and the outlet nozzle for the gas, the end of this rod which is near to the burner being attached to the clamping device, while the other end is so formed that it may be forced against the nozzle to close it.

Low-Temperature Carbonization.—No. 229,880.

Zuyderhoudt, P. C., of Brussels.

No. 7262; March 21, 1924.

The object of this invention is to provide an oven for producing continuously low-temperature coke in the form of cakes, and for recovering the distillates. An elevated ring oven is provided comprising a series of chambers each containing a battery of retorts and having means for connecting them with each other, with the outside air, and with a waste-gas flue. The chambers extend over a free space of a depth at least equal to that of the retorts. This is for discharging purposes. Discharge is effected by lowering the bottoms of the retorts. In operation the retorts are entirely surrounded by the heating atmosphere of the chambers.

Coke Ovens.—No. 230,167.

Mellersh-Jackson, W. J., of London.

(A communication from the Koppers Company, Ltd., of Pittsburg.)

No. 30,490; Dec. 4, 1923.

This invention relates to regenerative ovens with retorts alternating with heating walls containing vertical heating flues porting at their upper ends into horizontal distributing channels. The invention has for its chief object to permit a considerable reduction in the capacity of the latter channels, with corresponding increase in the effective heating area of the heating walls, while permitting the employment of the system of flow through the walls, wherein upflow in the vertical flues of one group takes place concurrently with downflow in the flues of another group in the same heating wall. A communication duct is located at a higher level than the retorts, and connects the horizontal distributing channel serving a group of upflow combustion flues with a horizontal distributing channel in the same heating wall and serving a downflow group of flues.

Wet Meters.—No. 230,175.

Thorp, F., and Parkinson and W. & B. Cowan, Ltd., both of Kennington, S.E. 1.

No. 30,619; Dec. 5, 1923.

This invention relates to wet gas-meters of the type wherein one or more oscillating liquid-sealed bells are coupled to a rocking lever or levers or other mechanism, and thus also to the gas distributing mechanism. The object is to ensure that operation of the meter shall be prevented should the liquid within the meter exceed a predetermined level.

There is provided an auxiliary valve upon a float-controlled stem which is closed to prevent a flow of gas when the liquid exceeds the predetermined level; and this auxiliary valve is mounted above and on the same stem as the ordinary stop valve.

Water Gas Production.—No. 230,217.

Whitwell, G. E., of Tacoma, Washington.

No. 966; Jan. 12, 1924.

This invention relates to a process of making water gas and to apparatus therefor.

According to the invention, part of the run is effected by passing a mixture of fresh gas-making steam and gas successively through a recuperating or superheating vessel or vessels and the entire fuel bed in the generator, and another part by steaming the entire fuel bed in the opposite direction. The run with fresh gas-making steam and gas preferably follows the blasting of the fuel bed and the up run of steam, and takes the place of the so-called down run of steam, which is expensive and wasteful through the steam of the customary down run not being superheated. The patentee further points out that the back run of steam and gas effected in accordance with his invention cleans the checker brick when oil is used, removing carbon deposit therefrom and increasing the yield of gas. The steam which passes successively through the superheating vessels and generator, produces gas; and a portion of this is repassed with steam through the vessels and generator, and forms, with the steam, the mixture of steam and gas above referred to. It is claimed that the invention decreases the cost of maintenance of the apparatus and permits the use of cheaper low-grade oils as the enriching material; further, that the generator be charged with other fuels than coke or anthracite.

The apparatus for carrying out the process above described includes a generator and a superheater or recuperator, and if desired a carburettor there-between; means being provided, including a device such as a jet, for causing a back run of gas through the apparatus. As in well-known gas-making plants, there is a main passage from the generator, through the superheating vessel or vessels, to a wash-box or the like. According to the present invention, a second passage is provided from the generator to the wash-box, these two passages having a by-pass connection with each other in which the steam jet is located, the by-pass preferably connecting with the main passage between the superheater and the wash-box, although it falls within the scope of the invention to connect this by-pass with the main passage at some other point.

After describing in detail the apparatus, the specification states that the act of recirculating the gas has a most important and beneficial effect upon the economical operation of the set in the manufacture of carburetted water gas.

First, a larger volume and weight of gases is passed through the superheater and carburettor than if steam alone were so passed, thereby transferring to the generator (where it can do useful work) heat contained in the superheater and carburettor otherwise wasted.

Secondly, when blue gas is passed a second time through the fire-bed, the carbon dioxide contained therein is afforded another opportunity to become reduced to the more valuable carbon monoxide.

Thirdly, the capacity of the machine is greatly increased. When steam reacts with incandescent carbon, two main reactions are possible according to the temperature and concentration of the reacting substances:

$$H_2O + C = CO + H_2.$$
$$2H_2O + C = CO_2 + 2H_2.$$

The first of these two is the one most desired in making carburetted water gas. Maximum capacity, among other things, requires maxi-

mum passage of steam. The amount of steam possible to be used, however, is limited by a further reaction:

$$H_2O + CO = CO_2 + H_2.$$

Too much steam, therefore, results in the formation of carbon dioxide, so undesirable as to limit the amount of steam usable and, with it, the capacity of the set. Recirculation of considerable portions of the back run gas permits of the use of excess steam and the attainment of increased capacity, because carbon dioxide formed is later reduced to carbon monoxide by again passing through the fire-bed and coming in contact with incandescent carbon—thus:

$$CO_2 + C = 2CO.$$

Fourthly, inasmuch as in any water gas set steam in excess of that theoretically required must be used, there is always an excess of steam which passes undecomposed through the fire-bed. Recirculation, however, provides for a repassage of some of this steam through the fire-bed, thus reducing the amount of steam which must be supplied from the boilers.

Fifthly, there is a reaction between the superheated back run steam and recirculated back run blue gas, whereby carbon dioxide is formed from the carbon monoxide of the blue gas. This reaction may take place either in the superheater or in the carburettor, or in both, before the gases reach the generator; thus:

$$CO + H_2O = CO_2 + H_2.$$

The carbon dioxide formed is later reduced to carbon monoxide by passage through the fire-bed. Because of this reaction, however, the gas-making portion of the set is thereby increased to include the carburettor and superheater as well as the generator, thus increasing the capacity of the set.

Washer-Scrubbers.—No. 230,243.

Kirkham, Hulett, & Chandler, Ltd., Hersey, S., and Stokes, F. W., all of Norfolk Street, W.C. 2.

No. 3427; Feb. 9, 1924.

This invention provides for a modified design of the well-known apparatus wherein bundles of metal plates are arranged between a pair of circular end or cover plates. The object of the modification is to increase the rigidity of the rotating members, to facilitate the carrying of wider bundles, providing increased washing area, to provide for the easy removal of the bundles for cleaning, and generally to reduce the cost of manufacture.

To this end, each bundle is mounted in a framework carried by a hub on the driving shaft in such a manner that the end plates of each bundle are sealed in the framework, thus avoiding the use of end or cover plates.

In a suitable construction, the framework is built up of a series of T bars extending radially in pairs from the driving hub. The periphery of the latter is advantageously made polygonal or with flats, and the pairs of bars extend from the angles at the lines of intersection of adjacent flats, being so placed that the webs of the bars of each pair extend inwardly in the same radial plane and their flanges lie in the outer face of the framework. These radial bars are rigidly connected by circumferential bars or strips attached to adjacent flanges on each face or side of the framework.

Alternatively, the framework may be built up of a series of flat bars, instead of T bars, extending radially in pairs from the driving hub. In this case the two outer plates of alternate bundles of plates are preferably made wider than the inner plates, so that they overlap the outer plates of the adjoining bundles where they make contact with the bars.

The casing of the apparatus is advantageously of rectangular form in cross section, and the flat top thereof can serve as the bottom of a tank for water for cooling the casing.

Carbonization.—No. 230,281.

Imray, O. Y., of London.

(A communication from S. P. Curtis, of Philadelphia.)

No. 7502; March 24, 1924.

The process is for the manufacture of hard low-volatile coke, and gas of relatively high calorific value, together with the recovery of oils. It consists in heating the coal in a chamber having a centre take-off duct; causing the liquids, gases, and vapours evolved at the low temperatures to travel through the coolest portion of the material in the chamber and escape therefrom before they can undergo secondary decomposition; carbonizing at a high temperature the coked residue; maintaining a plastic film in the body of material in the chamber, which separates and protects the liquids, vapours, and gases escaping through the coolest portion from the high temperatures used to carbonize the coked residue, and from contact with the high-temperature gases evolved from this coked residue; and causing the high-temperature gases to escape freely through an outlet distinct from the one through which the low-temperature products escape.

Gas Cookers.—No. 230,506.

Helps, G., of Nuneaton.

No. 22,673; Sept. 10, 1923.

By this invention the flue pipe from the outlet nozzle of the cooker is brought down to a level just above the burners in the oven, or below them, as experience with a particular oven proves necessary. Such an arrangement, claims the patentee, balances the pressure inside and outside the oven. The waste occasioned by the oven being open at the bottom is neutralized, as the pull on the outside air would only be that measured by the difference in the levels of opening and the flue pipe end. Instead of bringing down the flue pipe as described, an orifice may be made in the closed bottom, which will answer the same purpose.

Geysers.—No. 230,525.

Gausden, A. H., of Wallington.

No. 28,936; Nov. 16, 1923.

This invention relates to geysers of the instantaneous hot water type, and has for its object an improved construction whereby water is caused to flow by pressure up the jacketed sides of the geyser, and then by gravity over a number of flat spirally corrugated metal plates in a zig-zag manner.

Gas Meters.—No. 230,582.

Anderson, J., of Edinburgh.

No. 867; Jan. 11, 1924.

This invention relates to valves for prepayment gas meters. During and since the war, states the patentee, difficulty has arisen with the operation of meters owing to the fact that the gas contains more matter in suspension than previously, causing the deposition of grit on the valve and its seating, preventing full closure. The object of the invention is to overcome or minimize this difficulty. The invention consists in the employment of a valve of a rotating or sliding type—as distinct from the usual form of valve—preferably one comprising a cup or disc with a ground face mounted on a pivoted arm and capable of being moved over the ground face of a port with a guiding extension.

No. 230,583.

No. 868; Jan. 11, 1924.

This invention relates to prepayment mechanism, and its object is simplification. It consists in measuring-out mechanism comprising a pair of gear wheels mounted on different axes; the smaller operated from the prepayment mechanism, and the larger carrying, or controlling, means (such as a further wheel) for effecting control of the valve by a screw acting both as a rack and also as a worm, and in addition operating an indicator.

Gas Burners.—No. 231,115.

Helps, G., of Nuneaton.

No. 529; April 7, 1924.

By this invention the adjustment of the air to atmospheric burners may be regulated automatically. A gas burner is provided with means whereby the turning of a tap partially to shut off the gas causes the partial closing of a restricted passage in the plug, which passage acts as the injector nipple.

South Metropolitan Gas Company.—See Conlay, C. No. 9540.
Wilderspin, G. H.—"Gas retort furnaces." No. 9195.

Profit-Sharing.—At a conference of directors, managers, foremen, and forewomen held at Oxford last week, Mr. Duncan Todd, a Ministry of Labour official, said that the gas industry was the only one in this country which had been largely reorganized on a co-partnership basis; and the success attained had been mostly due to the strenuous advocacy of the principle by Sir George Livesey and his successors as Chairmen of the South Metropolitan Gas Company.

A Loss at Conway.—The accounts of the Gas Department of the Conway Town Council show a surplus of £2724 8s. 7d. on the revenue account, but after meeting redemption and interest on loans this was converted into a loss of £737 7s. 8d., which increased the deficiency to £11,893 4s. 8d. The balance-sheet shows that £56,029 1s. 2d. was expended on the works, and including the amount overspent up to date shows an excess of assets over liabilities of £14,967 16s. 6d. The make of gas per year has increased from 13,391,000 in 1899 to 56,111,000 c.ft. in 1924, and the gas produced per ton of coal has increased in the same period from 8058 to 12,692 c.ft.

MISCELLANEOUS NEWS.

GAS REGULATION ACT APPLICATIONS.

The following notices have appeared in the "London Gazette" re-arding applications to the Board of Trade under the Gas Regulation ct.

SPECIAL ORDERS.

Midhurst Gas Company, Ltd.

An Order under section 10 is to be applied for by the Company to thorize them to use scheduled land for gas purposes, to supply gas various parishes, to make provisions as to capital, to prescribe gas ices and rates of dividend, and to formulate regulations regarding e supply of gas.

Southampton Gas Light and Coke Company.

The Company are applying to the Board of Trade for a Special rder to extend the limits of supply, to increase the maximum rates dividend and borrowing powers, to authorize the establishment of co-partnership scheme, to make further provisions with regard to e issue of capital and the supply of gas, and for other purposes.

METROPOLITAN GAS COMPANY OF MELBOURNE.

The half-yearly meeting was held at the offices of the Company, linders Street, Melbourne, on January 28—Sir JOHN GRICE (Chair-an) presiding.

The CHAIRMAN said that the cost of coal for the half-year amounted £305,951.

The revenue from the sales of gas—£659,647—showed a decrease £2677 in comparison with the corresponding period of 1923, due reductions in the price, which was now 6s. 8d. per 1000 c.ft.

The total quantity of gas sold during the half-year was 1964 million ft., as compared with 1819 millions during the corresponding half 1923—an increase of 8·01 p.ct.

From residuals the receipts were £150,204—an increase of £9556 er the corresponding period in the previous year. The operations the stove and fittings department again showed very satisfactory sults. Special efforts, by means of suburban cookery demonstra-ons and canvassing in various suburbs to increase the use of gas ooking stoves, had resulted in an output of these for the year of 51, as compared with 7838 last year. Sales of other appliances had et with a good response.

The number of meters fixed at Dec. 31 was 168,928, as compared ith 166,513 at the same date last year. The profits for the half-ear under review amounted to £138,677, from which sum transfers £41,763 had been made to the reserve fund, £5000 to the meter enewal fund account, and £10,000 as a nucleus of a staff superannua-on fund, leaving a balance of £81,914. It was recommended that dividend at the rate of 7s. 6d. per share be declared, absorbing 82,197, leaving an amount to be carried forward of £71,778.

During the half-year 14½ miles of service mains and nearly 4 miles f trunk mains were laid, in addition to 57 miles of services.

The continuous vertical carbonizing units at the West Melbourne Vorks, as recently improved, continued to give the greatest satis-ction.

At the last half-yearly meeting they were informed that the Direc-ors were issuing 20,000 new shares of £5 each. Of these, 14,824 ere disposed of for an amount of £107,566 15s.—an average of 7 5s. 1·5d. per share. The balance of 5176 shares unsold at the uction were offered to shareholders as follows: In the Common-ealth, 4387; in Great Britain, 789. At the upset price of £7 5s. er share, the whole of the 4387 shares offered to Commonwealth hareholders were taken, the amount received being £31,805 15s. Of the 789 shares similarly offered to English shareholders, 342 were ccepted, leaving a balance of 447, which were disposed of in Mel-ourne in November last for £3479 7s. 6d.—an average of £7 15s. 8d. er share. The total net premium received from the issue, after pay-ent of all expenses, including printing, brokerage, and advertising, as £43,527, which was credited to premium capital. Debentures to he amount of £38,000 at 4 p.ct. fell due on Oct. 1, and the Directors ecided to issue a conversion loan of 6½ p.ct. debentures at £98 10s., vith a currency of eleven years. Holders of the maturing debentures onverted to the extent of £15,700, the balance of £22,300 being ubscribed by the public. The Company had considerable commit-nents which might render it advisable to make a further issue later n the year.

Mr. G. S. ALLEN moved: "That a dividend at the rate of 7s. 6d. er share for the half-year on 218,386 shares, and at the rate of 3s. 9d. n 1614 shares issued on Oct. 1, 1924, be declared."

Mr. J. WALKLATE seconded the motion, which was agreed to.

Newtownards Gas-Works Loan.—At a Ministerial Inquiry into he application of Newtownards Town Council for sanction to bor-ow £6000, and to have a running overdraft of from £8000 to £10,000 funded as a loan, the Town Clerk said the loss on the gas ndertaking was occasioned by war conditions, &c. For the year nded March 31, 1919, the loss was £2386; 1920, £1977; 1921, £1807; and 1922, £3016. The concern had been holding its own or the last two years. Mr. John P. M'Ilwaine (the Gas Manager) ave evidence as to the consumption of coal for the years 1919 to 1923, nd detailed the cost of production and distribution of gas; pointing ut that the loss, in a large measure, was due to the small consump-ion, particularly by the factories, which had given up the use of as engines and installed crude-oil engines as a cheaper means of riving their machinery.

THE AUSTRALIAN GAS LIGHT COMPANY'S WORK AND PROGRESS.

From a Souvenir Booklet.

The history of the gas industry in New South Wales extends over the reigns of five monarchs of England, for, as far back as the days of King George IV., the pioneers of Sydney considered lightening the gloom of their straggling streets by the then newly discovered illuminant—gas. Their consideration took definite form in the reign of the next Sovereign, William IV. In 1837, just prior to Queen Victoria's accession to the Throne, a quaintly worded Royal Charter gave power for the formation of the Australian Gas Light Company, for the purpose of "effectually lighting the said town of Sydney." At that time the entire white population of the infant Colony of Australia numbered only 150,000, but what the pioneers of Sydney lacked in numerical strength they more than made up in courage and enterprise. They launched the first gas company in Australia only twenty-five years after the incorporation of the first in the world—now the Gas Light and Coke Company. The gas undertakings of Paris and Berlin came into being a few years earlier than that of Sydney.

To celebrate the birthday of Queen Victoria, May 24, 1841, the streets of Sydney were first lighted with what the Press of the day, in its enthusiasm, described as "this exquisite production of science . . . this pure, brilliant, and inoffensive illumination of gas."

Literally, the Australian Gas Light Company was founded upon a rock, the sites for the first works, gasholder tanks, and offices being actually hewn out of the solid sandstone at Darling Harbour. Each of the first two holders had a capacity of 45,000 c.ft., which the Directors of those days referred to as "being sufficient to store up a superabundant stock of purified gas to meet any emergency, the 90,000 c.ft. of storage being considered more than adequate for all the wants of Sydney for many years to come." How far along the road of progress the Company has advanced since then is shown by the fact that it now has five holders with a total capacity of nearly 20 million c.ft., one of which is the third largest in the world, while during the last fiscal year no less than 406 million additional c.ft. of gas had to be made. The make of gas now reaches an annual total of just on 7000 million c.ft.

From the small concern of the early 'forties, the Company has grown to be the seventh largest gas undertaking in the British Empire, while it is rapidly overhauling the gas companies of the great cities of Manchester and Liverpool for the honour of fifth position.

New South Wales is blessed with a wealth of coal, but that wealth must be conserved. The Australian Gas Light Company is in line with the gas industry generally in the economical utilization of the world's coal resources. Recognizing the national need for extended use of gas as a substitute for the wasteful burning of coal, the Company is encouraging gas utilization by the introduction of concessions in price and the provision of a special demonstration hall. This is equipped with up-to-date furnaces and appliances for the convenience of manufacturers desirous of making practical experiments, under actual working conditions, in the use of gas as an industrial fuel. Manufacturers find in the cheap rates for industrial gas a solution of one of their greatest economic problems, and they welcome the opportunity given by the Company to test its possibilities.

By the original Royal Charter of 1837 the capital of the Company was limited to £100,000, but this restriction was removed by subsequent legislation. To-day capital stands at nearly 4½ million pounds sterling, which has been contributed by over six thousand share and debenture holders, most of whom are actual customers of the Company. A big percentage of the employees are also shareholders, a fact which gives them a personal interest in the organization which they serve. With the shares of the Company spread over so great a number of stockholders, and with the customers and staff taking part in the financing of the concern, the Australian Gas Light Company is a co-operative organization in the true sense.

The Company, in its works, out-stations, branches, and head office, employs 3000 people; the wages and salary bill amounting to well over £800,000 per annum. The relations between the Company and its employees are harmonious, which is due in great measure to the smooth working of the conciliation systems in operation. This happy condition of affairs has been more marked since 1920, when an agreement was completed between the Company and the Gas Employees' Union, which represents the main body of the workers. This agreement was the basis for a system of conciliation unique in the industrial history of the Commonwealth; all disputes and labour difficulties now being settled in an atmosphere of reason around the table of the Conciliation Committees. The success achieved by these Committees has been remarkable.

A keen interest is taken by the Company in the educational efforts of its staff; and fees are advanced for tuition in approved commercial subjects. An extensive welfare scheme has been inaugurated, and is enthusiastically supported by the staff. Comfortable rest and luncheon rooms, medicine chests, nursing attention, and facilities for social functions are provided, under the care of a Committee elected by the staff from among its members.

Winchester Preference Stock Over-Subscribed.—An issue by the Winchester Water and Gas Company (which was made locally) of 5½ p.ct. preference stock has been largely over-subscribed—practically all those tendering at par having to remain unsatisfied. Announcing the result, a Winchester paper says: "That the stock in a local undertaking should command such attention must be very gratifying to the Directors and stockholders, and is evidence that it is widely realized that the citizens of Winchester are well served in their water and gas supplies."

COLOMBO GAS AND WATER COMPANY, LIMITED.

Annual General Meeting.

The Annual General Meeting of the Company was held at the Offices, No. 148, Gresham House, Old Broad Street, E.C., on Monday, April 6—Mr. Strachan C. Clarke (Chairman) presiding.

The Secretary (Mr. A. C. Pullen) read the notice convening the meeting and the Auditor's report.

The Chairman: Gentlemen, a copy of the report and statement of accounts having been sent to all the shareholders, I will ask you to take them as read. One of the Directors, Mr. Robert H. Glen, is not able to be with us to-day, as he is now on his way to the East, and will be at our Colombo Works on the 18th inst. During his stay in Ceylon, he has undertaken to report to the Board as to land which may be available, as we should be prepared for future extensions.

I am pleased to state that the total gas sold during the year was 13·5 p.ct. more than in 1923; the private consumption being equal to 82 p.ct. of the whole. To encourage the use of gas for cooking and heating, we arranged last year a specially low rate for same; and at the end of August a scheme was started for fixing cookers entirely free to consumers—a moderate rental being charged for the cooker itself. At our last annual meeting I referred to the fact that the Ceylon Government had passed the hydro-electric scheme, and the work of construction is now proceeding. It is therefore very necessary for this Company to obtain all the trade it possibly can in gas for heating, and no effort to that end is being spared. The total number of cookers in use at Dec. 31 last was 423, compared with 209 at the end of 1923; so we have doubled the number in one year.

The alterations and extensions at our works have been completed; and, as we have now sufficient plant to meet the gas requirements of Colombo for very many years, we hope business will continue to forge ahead rapidly. An amount of £14,906 has been added to capital account in connection with extensions, and £4000 has been appropriated from the retorts reserve for the renewals and replacements. The walls and roof of the old retort house were taken down, and the building was reconstructed; fresh retorts and mouthpieces being supplied for old beds. Reference to the capital account will show also that we paid off debentures amounting to £3800 during last year. A few further bonds were paid off on Jan. 1 last, and debentures amounting to £3300 fall due on July 1. These will be repaid, and the Company's total debenture debt will then amount to only £3950; the bonds being met as they mature.

We carbonized 679 tons of coal more than in 1923, but the total cost for coal is somewhat less. The average rate per ton for 1925 will show a further considerable diminution, and reductions in the gas rates consequently came into force as on the 1st inst. at Colombo. The average of gas made per ton for the year was 14,513 c.ft. of 450 B.Th.U.; and these figures, produced as they are from Indian coal and with native labour, are highly satisfactory, and reflect the greatest credit on our Manager. I may say that the make per ton for February this year was 16,666 c.ft. We hope to show an average make for the whole of the year considerably in advance of the 1924 figures.

The total for wages and salaries is about the same, and includes the bonuses paid on profits to all local employees from the Manager to the lowest workman. The Directors attach much importance to this profit-sharing arrangement. Maintenance of works and plant is slightly higher. We paid in 1923 for two new motor lorries, but in 1924 there was more expenditure on the works. Maintenance of mains shows a figure of Rs. 20,334, which is not a high cost. The total mileage of mains is 106. Trade charges was rather more; but the cost of advertising, included in this account, went up from Rs. 1583 to Rs. 6841, partly counterbalanced by the fact that we received considerable sums for the use of the Company's weighing scale, which moneys are credited to trade charges. Our Manager pays particular attention to the work of propaganda, and specimens of our advertisements and pamphlets are about these rooms.

On the credit side of the revenue, I would point out that gas rentals improved by Rs. 33,740. The quantity of gas sold private increased by 14 millions, and public by 2¾ millions; these increases in sales being offset to some extent by the reduction in prices. The revenue from residual products was considerably higher; coke sales being increased by 770 tons, and tar sales by 31,574 gallons. The net coke available for sale amounted to 9·93 cwt. per ton—a most satisfactory feature of our working. The percentage of the value of residuals on cost of carbonizing material for last year was 81 p.ct. Gasfittings account showed improvement. We made additional profit on the erection of new arc lamps, brackets, &c. Exchange account shows a credit arising from adjustment of remittances and shipments. I would point out that our assets remain in the books at 1s. 4d. per rupee, although the rate on Dec. 31 was over 1s. 6d. I think these are all the comments needed on the accounts.

The balance of net revenue is £28,509 17s.; and the Directors recommend a final dividend of 3½ p.ct. on the preference shares, less tax, and a final dividend on the ordinary shares of 5 p.ct., free of tax, also that £10,000 be added to the general reserve. Here I would remark that, from advices just received, the output of gas at Colombo for the past three months increased by 11¼ p.ct., the gas made per ton averaged 16,153 c.ft., and the rupee profit showed improvement.

I now come to a matter which has been engaging the attention of the Directors for some considerable time. Our general reserve account, after adding the £10,000 now recommended, will amount to £35,433; and we have other reserves. Investment account stands in our books at £42,693, and if the bank loan of £12,500 be deducted there is a credit balance of over £30,000; so that our financial position is very satisfactory. For some time the Directors have felt that the Company's proprietors, who in years gone by waited so patiently for a fair return on their shares, should benefit by our present position; and the Board recommend that bonus shares be issued to the ordinary shareholders at the rate of one bonus share for each three ordinary shares held. We have also decided to ask your acceptance of new Articles of Association, in order that our shares may be officially quoted on the Stock Exchange. The Committee will not, at present, sanction the request for a quotation, on the ground that our Articles are out of date. As the Company was established in 1869, we can well understand this view. We further consider that the ordinary shares should be converted into shares of £1 each from the present figure of £10 each. Extraordinary meetings will be called shortly to place these proposals before you in detail, and to ask you, if thought fit, to give effect to same.

Before I sit down, I wish to again refer to Mr. Johnson, our present Manager. I have already mentioned, among other features of our working, the carbonizing results obtained last year; and the Directors are in every way most pleased with everything that Mr. Johnson is doing for the Company. He does not spare himself, and it is right that I should draw your particular attention to what he is doing for us. With these remarks, I have pleasure in moving that the report and accounts be received and adopted.

Mr. John G. Wardrop seconded the resolution.

Mr. Alfred W. Oke remarked that the shareholders fully appreciated the policy of the Board, and were pleased with the results of same.

Mr. A. J. Kingdon said that the Directors were to be congratulated in being able to bring forward such an excellent report and accounts. Much praise was due to the Engineer at Colombo for the very able manner in which he had managed the affairs of the Company there; also to the Secretary in London for the keen manner in which he undertook his duties. In obtaining over 81 p.ct. of cost of coal from residuals, the Engineer had recorded a result rarely heard of, even in England. This also indicated that the Board had been well advised in the purchase of coal.

The Chairman then put the motion to the meeting, and it was carried unanimously.

The Chairman moved the following resolution—viz.:

"That a dividend for the year ended Dec. 31, 1924, at the rate of 7 p.ct. per annum upon the preference shares, less income tax, and 10 p.ct. per annum upon the ordinary shares, free of income-tax (both less interim dividend paid on Oct. 1, 1924), be and is hereby declared, the warrants to be payable on April 17."

This was seconded by Mr. John G. Wardrop, and carried unanimously.

The Chairman then proposed the re-election of Mr. Robert H. Glen as a Director, which was seconded by Mr. Alex A. Johnston who remarked on the great value of Mr. Glen's services to the Board. Mr. Johnston said that, although he personally had only been on the Board a short time, he could see that the Company's position was due to able direction and management. The future prospects were good and the time was ripe for the issue of bonus capital referred to by the Chairman. Even after the addition to capital account of a further £20,000 ordinary shares, the Company's capital per million c.ft. of gas sold would compare favourably with that of English companies of a similar capacity.

The motion was unanimously carried.

Major Heriot R. Glen proposed the re-election of Mr. William Cash as Auditor for the current year, which was seconded by Mr. A. J. Kingdon, and carried unanimously.

The Chairman proposed a vote of thanks to the staff in London and Colombo. He said the Company's present position was largely due to the hard work of the Secretary, who was of the greatest assistance to the Board. He could add no more as to the Manager, except to say that Mr. Johnson was coming home this year on leave, and might visit England more often than in the past.

Mr. A. J. Kingdon said he wished cordially to second the motion which was carried unanimously; and the Secretary briefly responded.

Mr. Alfred W. Oke proposed a hearty vote of thanks to the Chairman and Directors, and remarked that the Chairman had given shareholders some very welcome news. The Company was progressive, and was very competently managed.

Mr. H. Gage Edwards seconded the resolution, which was unanimously carried, and the proceedings then terminated.

Riscavoid.—This is the title of a Company registered, with a capital of £500, to acquire inventions relating to a device for the automatic closing of gas ducts when the supply of gas ceases or falls below a predetermined pressure.

New Capital for Littlehampton.—To provide the necessary extensions to cope with the growing demand for gas, the Littlehampton Gas Company require further capital; and accordingly Messrs. A. & W. Richards have been instructed by the Directors to offer for sale by tender £5000 of 6 p.ct. redeemable debenture stock, at the minimum price of par. Tenders must be received by the firm at No. 37, Walbrook, E.C., by Tuesday morning, April 28.

Price of Gas at Dunfermline.—A possible rise in the price of gas during the current year, in view of the fall in the value of residuals, was hinted at recently in the Dunfermline Town Council; but a statement made at last week's meeting showed that after all there would be no need for this. The Convener of the Gas Committee (Mr. Smith) announced that they had just completed the purchase of 20,500 tons of coal for the year, at an average cost of 19s. 7d. per ton, or 5s. 2d. less per ton than the previous year's supply. He was of the opinion that at the price mentioned the decrease of revenue from residuals would be balanced by this saving, and therefore the price of gas would remain at 2s. 6d. per 1000 c.ft.

The Team By-Product Coke Company.—The Company experienced a setback in the year ended Nov. 30, 1924; a loss of £40,107, after providing for taxation, being recorded, as compared with a profit of £52,501 for the previous year, and a loss of £31,595 for 1921-22. The Directors state that the economic dislocation on the Continent, which resulted largely from the Ruhr occupation, prolonged the severe depression in the iron trade, and caused during the year a disastrous reduction in the demand for coke. As a result, it was impossible to keep the Company's works fully employed; and the average production over the whole year was equal only to 70 p.ct. of the normal output. Since the end of the financial year the volume of business has increased, and the works are now on approximately full output.

NORTH-EAST COAST COAL TRADE.

From our Own Correspondent.

The market returned to business after the Easter break without finding any improvement in conditions. Many of the collieries which are working have fairly full turns for a week or so ahead; but forward inquiry does not show any signs of developing, and the outlook for the end of the month and later is as bad as ever.

At the end of last week it was stated that 75 out of scarcely 200 pits in Durham had been closed entirely, and 40,000 men were idle. In addition to this, there are thousands who are working short time. Orders continue to go to Germany, at prices from eighteenpence to three shillings a ton below English quotations.

Durham gas coals are in poor demand, like all other sorts. Wear Specials are nominally 20s. f.o.b., and best qualities 19s. 6d. to 19s. 9d. They are fairly steady at these prices for prompt; but they can probably be discounted for forward business. Seconds and others are weak, and some makes obtainable at 16s. 9d., though nominal quotations are 17s. to 17s. 3d. The market for coking sorts is lifeless, and prices are 17s. to 17s. 6d. Unscreened bunkers are 17s. to 18s. 3d., according to quality.

YORKSHIRE AND LANCASHIRE COAL TRADE.

From our Local Correspondent.

There is no appreciable difference in the coal market conditions in Yorkshire and Lancashire as compared with recent weeks.

Gas coals move steadily under contract, with indications of slightly decreased prices for renewals.

House coal remains steady, and there is no indication that prices will be lower in the near future.

The industrial situation does not improve, and "spot" lots of the lower-grade fuels are available at prices below the average; but these are not being taken advantage of, owing to the difficulty of dealing with contract supplies to which the consumers are already committed.

The slump in export continues, and it is questionable when the position will improve.

Prices at Hull at the week-end were (f.o.b. usual shipping ports): South Yorkshire: Hards, Association, 19s. 6d. to 20s. 3d.; screened gas coal, 19s. to 19s. 6d.; washed trebles, 20s. 6d.; washed doubles, 17s. to 17s. 6d.; washed singles, 17s. to 17s. 3d.; washed smalls, 13s. to 14s.; unwashed doubles, 15s. 9d. to 16s. 3d.; rough slack, 10s. 10½d. to 11s. 6d.; smithy peas, 20s. to 20s. 6d. West Yorkshire: Hartleys, 17s. to 18s.; screened gas coal, 18s.; washed trebles, 18s. to 19s.; washed doubles, 17s.; washed singles, 16s.; washed smalls, 12s. 6d. to 12s. 9d.; unwashed trebles, 18s.; unwashed doubles, 13s. to 14s.; rough slack, 11s.; coking smalls, 10s. to 11s. Derbyshire and Notts: Top hards, 19s. 3d. to 20s.; washed trebles, 18s.; washed doubles, 17s. 6d. to 18s.; washed singles, 17s.; washed smalls, 13s.; unwashed doubles, 15s.; rough slack, 10s. 6d. to 11s. Yorkshire, Derbyshire, and Notts: Screened steam coal, 15s. to 17s. 6d.; gas coke, 21s. to 23s.; furnace coke, 17s. 3d. to 18s. 6d.

COAL TRADE IN THE MIDLANDS.

From our Local Correspondent.

Output is being further curtailed. The suspension of coal-getting during the Easter holidays has helped to relieve stocks at some of the collieries, but not to any very appreciable extent, inasmuch as industrial consumption has been on a much reduced scale, and comparative idleness has reigned in the distributive channels. In no direction is there any strain on transport. Values have naturally tended to depreciate. Old undertakings that are linked, so far as the regulation of wages is concerned, with more profitable properties which have a superior geographical position are in many cases drifting into a hazardous plight. There are grave misgivings with regard to not a few of them. The prickly subject of the seven-hour day is generally avoided in public discussion of the crisis; but it figures very prominently when possible remedies are being canvassed in circumstances which impose less restraint. Thoughtful men among the miners appreciate as thoroughly as anybody does the importance of lowering the cost of production, and it is believed that many of them would be ready to acknowledge the part which the output per man has to play in any solution of this side of the problem.

Cokes are increasingly plentiful. Some of the big gas-works which have been very sure of their grip of the market, and have been adamant respecting proposals to lower district prices, are showing anxiety to cultivate both the industrial and the household trades; the advance of the season aggravating their difficulties.

TRADE NOTES.

"Thermix" Air Heater and Emile Prat Mechanical Draught Systems.

Messrs. James Gordon & Co., Ltd., of Windsor House, Kingsway, London, W.C., are acting as successors to the late Major S. Utting for the sale of the "Thermix" air heater and Emile Prat systems of mechanical draught.

Meldrums' Gas Purification Plant.

Messrs. Meldrums, Ltd., of Timperley, near Manchester, have received an order from Canada for their gas purification plant. The order includes their improved patent gas washer-scrubbers (in duplicate), capable of dealing with 12 million c.ft. of gas per diem.

Falk Stadelmann Gas Cookers.

We have received from Messrs. Falk, Stadelmann & Co., Ltd., of Farringdon Road, London, E.C., a copy of their 1925 list relating to gas cookers and other cooking requisites. It deals with a large number of appliances for this important part of the business of gas undertakings.

The Davison-Waller Water Gas Plant.

Messrs. Davison & Partner, Ltd., of No. 11, Carteret Street, Queen Anne's Gate, London, S.W. 1, have forwarded a copy of their March booklet, which deals with the Davison-Waller water gas plant. It is of interest to mention that, since the publication of this brochure, repeat orders have been received from York, Dorchester, and Ashford.

Dixon's Silica-Graphite Paint.

The Joseph Dixon Crucible Company, No. 22, Duke Street, Stamford Street, London, S.E. 1, have published a new descriptive booklet about their silica-graphite paint. This paint, it may be mentioned, has been supplied in all parts of the world for over 55 years, for the protection of iron and steel structures, &c. It is now being manufactured in England by Mr. C. R. Averill, at the above address.

"A. & M." Pressure-Wave Controllers.

The County of Lanark, District of Middle Ward, have placed a contract with Messrs. Alder & Mackay, Ltd., of New Grange Works, Edinburgh, for a complete installation of "A. & M." patent pressure-wave controllers, to be fitted to all the public gas lamps coming under the Bellshill and Mossend special lighting district. This installation will represent 500 lamps, and will be operated from the Bellshill Gas-Works. The work is to be completed in readiness for next lighting season.

CONTRACTS OPEN.

Coal.

The East Dereham Urban District Council are inviting tenders for a twelve months' supply of screen gas coal or nuts. [See advert. on p. 266.]

Tenders are invited by the Gas Committee of the Todmorden Corporation for the supply of 10,000 tons of gas nuts. [See advert. on p. 266.]

The Thornton Urban District Council are asking for tenders for about 3000 tons of best screened gas coal, nuts, or slack, and 300 tons of steam burgy. [See advert. on p. 266.]

EXTENSIONS.

New Holder for Troon.

At a meeting of the Dean of Guild Court, Troon, on Tuesday of last week, the plans of a new gasholder on the north shore were passed, and the erection of same authorized. The estimated cost is £14,550.

CURRENT SALES OF GAS PRODUCTS.

The London Market for Tar, Tar Products, and Sulphate.

London, *April* 20.

There is a moderate amount of inquiry for pitch, and the price is nominal at about 41s. to 42s. per ton f.o.b. works.

Creosote is quiet at about 7⅛d. to 7¼d. per gallon net and naked at works.

Pure benzole and pure toluole are about 1s. 10d. per gallon; and solvent naphtha, 95/160, about 1s. 8d. per gallon.

Tar Products in the Provinces.

April 20.

The average values for gas-works products during last week were: Gas-works coal-tar, 28s. 6d. to 33s. 6d. Pitch, East Coast, 40s. to 41s. f.o.b. West Coast—Manchester, 35s. to 36s.; Liverpool, 36s. to 37s.; Clyde, 39s. to 40s.; Benzole, 90 p.ct., North, 1s. 6½d. to 1s. 7¼d.; crude, 65 p.ct., at 120° C., 10d. to 1s., naked at makers' works; 50-90 p.ct., naked, North, 1s. 6½d. to 1s. 7¼d. Toluole, naked, North, 1s. 6½d. to 1s. 7½d., nominal. Coal-tar crude naphtha, in bulk, North, 7¾d. to 8¼d. Solvent naphtha, naked, North, 1s. 5d. to 1s. 6d. Heavy naphtha, North, 1s. to 1s. 2d. Creosote, in bulk, North, liquid, 6¼d. to 6⅝d.; salty, 6d. to 6¼d.; Scotland, 5⅞d. to 6¼d. Heavy oils, in bulk, North, 6¼d. to 7d. Carbolic acid, 1s. 5d. to 1s. 6d. prompt. Naphthalene, £11 to £14; salts, £4 to £5, bags included. Anthracene, "A" quality 2½d. per minimum 40 p.ct., purely nominal; "B" unsaleable.

North Middlesex Capital Issue.—Messrs. A. & W. Richards, acting on the instructions of the Directors, are offering for sale by tender £16,000 of additional ordinary stock of the North Middlesex Gas Company, on terms which are announced in our advertisement pages.

Brentford Price Increase.—The Directors of the Brentford Gas Company regret that, owing to the reduced yield from residual products and to increases in the rates of wages paid, they are compelled to raise the price of gas by 0·8d. per therm as from the date of the reading of the indices for the June quarter. This increase—which is equivalent to 4d. per 1000 c.ft.—will necessitate a corresponding reduction in the dividends paid to the stockholders.

New Preference Capital for Andover.—The Directors of the Andover Lighting and Power Company are inviting tenders for £5000 of 6 p.ct. redeemable preference stock; the money being required to pay off a bankers' loan and to provide increased carbonizing and condensing plant rendered necessary by the growing demand for gas. The minimum price of issue is par; and tenders must be received by the Company, at No. 13, Bridge Street, Andover, by noon of May 12.

STOCK MARKET REPORT.

It was not to be expected that the reopening market, discouraged speculative dealings. The of the Stock Exchange after the Easter Holidays business continued to feel the effect days would be distinguished by any marked of the dearer money, and there was a slight increase of business; but it cannot be said satisfactory in quotations. In the Foreign Mar- that markets were dull, though transactions ket, in spite of the financial uncertainty, were few. The possibility of sensational happenings in France tended to keep dealers and French loans were steady. Home Rails were distinctly depressed. speculators alert until the formation of the The announcement of Cabinet and the passing of the "crisis" the intention of the Great Western Railway to reduce its staff forthwith, in consequence of afforded some relief. Anxiety with regard to lower traffic receipts, came as a shock to the the British Budget, and the rather stringent railway investment market, and prices weak- conditions which developed in the Money Mar- ened.

Quotations at :—*a*.—Bristol. *b*.—Liverpool. *c*.—Nottingham. *d*.—Newcastle. *e*.—Sheffield. * Ex. div.

The Industrial Market was steady, but there was very little business done. Courtaulds and Imperial Tobaccos were again exceptions. The price of these two companies' shares have been steadily advancing for some time, and there has been speculation as to which will reach the £5 mark first.

In the Gas Market the depression continues. It will be seen from the Table that Commercial 4 p.c.t. and all the Wandsworth stocks fell during the week. Although these stocks at the prices quoted are good investments, there is a possibility of a still further drop before the inevitable reaction occurs. The Brentford stocks were also marked down by as much as 2½ points. In view of the excellent terms of conversion provided by the Gas Light and Coke Company's Bill (which is now practically certain of becoming an Act), the fall is very remarkable. Primitiva ordinary advanced by 1s. 9d., to 10s.-11s.—a jump of no less than 20 p.ct. on the former average price, and, in view of the state of the Company's accounts, would, to say the least, seem to be scarcely justified.

An issue of interest to gas stock investors is that of the Tottenham District Company, who are offering £150,000 5½ p.ct. Irredeemable Preference Stock. Tenders must be received by May 1, and the minimum price of issue is par.

The following transactions were recorded during the week:

On Tuesday, Alliance and Dublin 60¼ ex div., Bombay 5⅞, Brighton and Hove "A" 123½, 124½, Bristol 94½, 94, Commercial 3 p.ct. debenture 58½, Gas Light and Coke 87, 87⅛, 87½, 88, 4 p.ct. preference 78¼, 78⅜, Imperial Continental 180½, 182, 3½ p.ct. debenture 73, Primitiva 8s. 6d., Tottenham "B" 98. Supplementary prices, Liverpool 5 p.ct. 87⅛.

On Wednesday, Aldershot "C" 78, Alliance and Dublin 67½ ex div., Bournemouth 6 p.ct. preference 11⅞, Cape Town 4½ p.ct. preference 6¼, Gas Light and Coke 87, 87⅛, 87½, 3½ p.ct. maximum 63, 63¾, 63⅞, 4 p.ct. preference 79¾, 3 p.ct. debenture 60¼, 60⅜, 61, Montevideo 65⅜, Primitiva 8s. 10½d., 9s., South Metropolitan 94⅜, 95, 95¼, Tottenham "A" 117, Wandsworth "B" 113, 114. Supplementary prices, British, Norwich, 3½ p.ct. mt. debentures 62, 4 p.ct. mt. debentures (Act of 1890) 71½, 72, Wandsworth New 95.

On Thursday, Aldershot "C" 80, Continental Union 30, Gas Light and Coke 86½, 86⅜, 87⅛, 87⅜, 3½ p.ct. maximum 64⅛, 4 p.ct. preference 79, 79⅛, 3 p.ct. debenture 61, 61⅛, Imperial Continental 181½, Montevideo 65⅝, Primitiva 8s., 9s. 3d., 9s. 6d., South Metropolitan 94⅜, 95, Tottenham "A" 117. Supplementary prices, Gas Light 10 p.ct. bonds 195, Grays and Tilbury "B" 8⅛, 8¼, Wandsworth New 95.

On Friday, Brentford "B" 95, 4 p.ct. debenture 76, Continental Union 30, European 7¼, Gas Light and Coke 86⅞, 86⅜, 87⅛, 87⅜, 3½ p.ct. maximum 64, 4 p.ct. preference 79⅛, Imperial Continental 180, 181, 182. Primitiva 9s. 6d., 9s. 9d., 10s., 10s. 3d., 4 p.ct. 1st debentures 80, 4 p.ct. debenture 63⅛, 64, South Metropolitan 95⅛, Wandsworth, Epsom, 115. Supplementary prices, Brentford 6 p.ct. mortgages 99, Hongkong and China 5 p.ct. debentures 92, Wandsworth new 96½, 97⅛, 98, 99, Watford 3½ p.ct. consolidated 90, 91.

As we have mentioned above, stringent conditions developed last week in the Money Market. On Friday 4 p.ct. had to be paid at the start for fresh money; but the position eased later, and 3⅜ p.ct. was the general rate. Treasury Bills showed an increase in the average rate at which they were allotted—£4 4s. 2·38d., or 10·2d. p.ct. above that of the previous week.

The Foreign Exchange Market was inactive, except for the improvement in the French franc. The rate, which had touched 04 earlier in the week, dropped to 01·40 on Saturday. Belgian francs were 04.85, and Italian lire 110⅝. Sterling was steady at 4·78$^{9}_{16}$.

Silver, with Indian and Continental selling, is inclined to fall, and the price for cash is 31⅞d. per oz. Gold was unaltered at 86s. 7d. per oz., with practically no dealings.

The Bank Rate is 5 p.ct., to which it was raised from 4 p.ct. on March 5. Bankers' deposit rates are 3 p.ct. The deposit rates of the discount houses are 3 p.ct. at call and 3¼ p.ct. at notice.

VOL. CLXX., No. 3233.] WEDNESDAY, APRIL 29, 1925. [77TH YEAR.

EDITORIAL NOTES.

The New Wembley.

In another twelve days the public will be flocking to the British Empire Exhibition; the reopening of which is to be performed by His Majesty the King on Saturday, May 9. Gas and the secondary products of its manufacture are to take their good part in the new display. We understand there has been additional demand on this occasion upon gas service to meet the requirements of the exhibitors; and it is well known that our primary commodity will have a considerable part in the work of the several caterers who will be dealing with the feeding of the great multitude during the six months through which the Exhibition will be open to the public. Regarding the Gas Exhibit, the features of it are to be entirely new, although the old setting will remain. But in addition to the industry's artistic buildings, further adjoining space has been taken, which will be a great convenience for cookery demonstrations and so forth. This will prevent the overcrowding which sometimes took place in the Exhibit last year, and will provide more seating accommodation for the many housewives who will be attracted by the lectures and the demonstrations of the methods of cooking Empire foods. An Imperial atmosphere will be introduced on this occasion by the exposition of the uses of gas—industrial as well as domestic—in our Dominions and Colonies. There is no doubt that the Committee, particularly those who are taking the most active part in the plans, have an intention even to outdo the scheme which proved so magnetic to the public during 1924. In addition to the Imperial feature, the domestic and industrial applications of gas at home will be kept well to the fore. The abilities of gas for labour-saving—so solving the troubles of the housewife, without (as is the case with a competitor) fear of collapse, and with the certainty of economy and high efficiency, if waste is not allowed—will also be continually proved to visitors.

The Gas Exhibit is to be full of movement. Prominently displayed on the main gangway, a motor manufacturing exhibit is being arranged, showing the important industrial uses of gas in that industry. A similar space on the other side of the pavilion entrance will show two gas-engines—one of them of 150 H.P., and over 9 ft. high—continuously at work, and, among other duties, supplying power to a gas wafer-baking oven, from which will be produced no less than 100 tins of wafers daily. Various other industrial appliances will be seen in operation. A working exhibit of pottery making with gas-fired furnaces, conducted by disabled ex-service men of the Ashtead Pottery, is certain to fascinate many. Another interesting section will show the applications of gas in various hobbies—such as woodwork, model making, metal work, and amateur wireless. What with the addition of daylight cinemas, illustrating the thousand-and-one domestic and industrial uses of gas, and cookery demonstrations and lectures, there is no fear of the live gas industry having an exhibit which lacks life.

There will again be the demonstration of high-power low-pressure lighting in the Amusements Park, and gas will be represented in the great housing exhibit in the Palace of Engineering. This exhibit, we are informed, will occupy at least 60,000 sq. ft., and every foot of the space will provide a practical detail in the solution of the housing problem. The main object is to prove, by the erection of actual full-sized houses, the economic and artistic use to which many new materials and methods can now be applied in the construction of houses. The buildings will be of varied types from working-class dwellings to country cottages. In the organization of this display, the Government are participating, through the patronage and advice of the Minister of Health; and municipalities, and those engaged in building by private enterprise, are co-operating to make the demonstration as comprehensive and up-to-date as possible.

It is also learned that the National Gas Council, through the Central Executive Board, have acquired space in the Chemical Section of the Palace of Industry for tar propaganda. The design of the accompaniments for this exhibit has been confided to the well-known artist, Mr. Norman Wilkinson; and he will, there is confidence, do credit to his subject. Here samples of road-making material will be exhibited, in addition to a stretch of tar-treated road; and at the stand literature will also be available descriptive of the advantages of tar in the construction or surfacing of roads. Steps are being taken to ensure that surveyors, chairmen of highway committees, and others interested in the road question will have an opportunity of seeing what we are assured will be a very interesting exhibit. The chemical industry will again this year occupy a prominent position. As last year, the display is being organized by the Association of British Chemical Manufacturers—a guarantee that it will be an interesting and comprehensive exhibit. A number of new features will be introduced, and the keynote will be information for the public. In the scientific section, it is proposed to show how strikingly connected are the various stages from basic materials to finished products. From the consideration of raw coal, the visitor is to be taken through the various stages of its distillation, the products resulting therefrom, such as tar and ammonia, the treatment of tar for the resulting intermediate products, which lead up to the manufacture of dyestuffs. The production of benzole, disinfectants, fine chemicals, medicinal products, and the numerous other chemicals obtained from coal will also be illustrated. The wonders of coal and its products are only partially realized by the public; but at this exhibition the scientists propose to be informative as to these things, which have such an important part in the service and economy of everyday life.

Of the Exhibition generally, it may be said that the interest which the Homeland, Dominions, and the Colonies are furnishing on this occasion will be an enlargement of that which was enjoyed by the public through the wonderful display of last year. From the marvels of our Empire, and the demonstrations of the relationship that exists between science and the things of everyday life, down to the amusements which will be provided, there will be something in the great display for every visitor, whatever his interests. Splendid and attractive as was the gigantic show last year, the one this year will be lighter and brighter, and will make its call to people far and near, even to those across the seas.

An Electrical Inquiry into Domestic Supplies.

A considerable amount of liveliness is noticeable in the electricity supply industry in respect of the exploration of conditions with a view to future developments. There is the Committee, who have been sitting under the chairmanship of Lord Weir, to whom the Government entrusted the task of advising them on the lines that should be adopted in regard to generation and distribution with the object of increasing the availability of electrical energy. The Minister of Transport and the Minister of Labour have been talking in charming language of the interest the Government are taking in the efforts to promote the coursing of electrical energy here, there, and everywhere. But the Advisory Committee have not, so far as we are aware, yet reported; and so we cannot think that the Government have at present any definitely moulded views as to the future, or the assistance they are prepared to render. Now the Electricity Commissioners have appointed a Committee to consider the questions of the development of domestic consumption and alternative methods of charging. The constitution of the Committee is purely electrical; it comprises members of the British Electrical Development Association, the Association of Electric Power Companies, the Municipal Electrical Association, and the Provincial Electric Supply Committee.

It is an interesting feature to find a Government Department concerning itself in this way in the business end of a statutory industry. The fact will undoubtedly have an influence within the industry if recommendations are made by the Committee which commend themselves to the Commissioners, and, through them, are endorsed by the Government. But as to the effectiveness of any recommendations that may be submitted, this will rest entirely with the public. The point has frequently been made by us—that with Government interest so manifestly directed towards the electrical industry, the policy the gas industry should pursue is the highest possible standard of service among the public. In that way it will best protect its interests. It may be frankly confessed that we shall be curious to learn the nature of the recommendations that are made by the Committee of investigation who are to advise as to the domestic development of the uses of electricity. In the first place, they are asked to consider and report what steps are being taken by authorized undertakers to encourage and extend the application of electricity to domestic purposes; the relative effectiveness of such steps; and what further steps could be taken to bring about an increased consumption of electricity in the household. It seems to us that the reference savours somewhat of a reflection upon the business acumen of the existing administrators and managers of electricity undertakings. The potentialities in domestic electrification differ in every area; and there can be no one formula which can have universal application to the encouragement and extension of the use of electricity. Because of the diversity of conditions, it is difficult to judge as to the "relative" effectiveness of the steps already taken to secure development. We may be pardoned for thinking that if electrical undertakings are administered and managed by competent men, they themselves have already considered the trading methods applied in other districts having correspondence with theirs, to ascertain whether or not they are superior to their own. But apparently the Electricity Commissioners do not regard the matter in the same light as ourselves, and are of opinion that the capacity of local administrators for judgment requires supplementing by an Advisory Committee drawn from the various organizations mentioned. Furthermore, one would imagine that all normal steps that can be taken to bring about an increased consumption of electricity are well known to the administrators and executive officials of electricity undertakings. It will be of little use for the Committee merely to present known and normal practices as the "further steps." These must be novel and therefore abnormal. Hence the interest there will be in seeing what the Committee will propose in their report. They will have to be clever if they can devise plans which have not been previously thought of and tried in the forty and odd years of the electricity industry's statutory life.

Then there is that eternal matter of tariffs. As long as there has been an interest on our part in the affairs of the electricity supply industry, the charges for electricity have almost constantly been the subject of attention and discussion. For electricity supply it is felt that something special in the nature of charging is needed. Apart from flat rates and discounts according to purpose and character of patronage, the method most favoured so far is the bi-part one—a fixed charge and a low price per unit. But in most cases the fixed charge is a percentage upon the rateable value of, or upon the floor area of certain rooms in, a house. This sounds ludicrous; but the fact remains that the men of the electricity industry have found nothing better. Neither system has, in respect of the fixed charge, any definite relation to the electrical requirements of the householder. Many electrical men are very properly of opinion that some two-part method should be devised, the fixed charge of which should have relation to the electrical requirements of the consumer. That is the only legitimate foundation for such a system; it is the only manner in which can be eliminated the injustices as between consumers which are found through the operation of the rateable value and floor area elements in existing bi-part systems. We rather think the Electricity Commissioners are surprised that more undertakings have not applied for permission to substitute a two-part tariff for the flat rate one—not compulsorily, but at the option of the consumer. The second item in the reference to the Committee asks them to investigate and report as to what methods of charging for domestic supplies could be authorized as standard ones (subject to the fixing of an appropriate quantum in individual cases) for adoption, at the option of authorized undertakers, in lieu of charging for the actual amount of energy supplied, or by the electrical quantity contained in the supply. There the Commissioners have set the Committee the task of attempting to discover something which the perennial exercise of the best brains in the industry has not yet succeeded in doing. Perhaps concentrated effort will be victorious where scattered endeavour has failed. There are words in the reference against which some existing consumers might protest did they know of them. They are "for adoption at the option of authorized undertakers." Some consumers, until they know of the method proposed to be substituted for (say) a flat-rate system, might object to the option resting only with the authorized undertakers. Now why not set this matter at rest, and get into uniformity with the gas industry? The domestic purposes other than lighting for which the electrical industry are heartily yearning are cooking and room and water heating. Then why not charge by the therm (which has direct relation to those uses), and so get the two competing industries on one basis? We can see the men of the electricity industry smiling over this; we agree there is room for the smile. We also concur in what will be their view, that they would be foolish to enter into competition on the basis of a unit of heat—100,000 B.Th.U.—such as has been applied by statute to the gas industry. But perhaps the Committee may think differently, and will at least take the idea into consideration, even though they reject it as being derogatory to the competitive position for heating purposes of the purveyors of electrical energy.

Then, we see, it may be necessary, in order that the Committee's recommendations may be effective, to make application for legislative powers. The Committee are, in fact, asked to report what legislative powers (if any) beyond those already conferred by the Electricity (Supply) Act would be required to give effect to any recommendations that may be made. If legislation is contemplated simply to make the recommendations permissive, then no harm would be done; but if compulsory application is in view, it would depend upon the nature of the recommendations whether or not the electricity industry would rebel against this method of altering their statutory powers and administrative rights.

We are of opinion there might be a serviceable extension of the reference to the Committee to cognate and, indeed, very pertinent matters. A couple may be suggested for the consideration of the Electricity Commissioners. The first is, What would be the effects in respect of electricity generating and distributing plants assuming these were called upon to give an amount of heat equivalent to the coal now used in a given district—particularly having regard to the seasonal requirements for room heating, the

vagarious temperatures in winter time, and the fact that the peak of the lighting load then obtains? The second point is, Is it to the country's economic advantage that coal should be used for the production of electricity for domestic heating purposes, in view of the efficiencies of generation, distribution, and utilization? Perhaps the Board of Fuel Research might be invited to aid the Committee, if the Commissioners can see their way to extend the scope of the inquiry in the manner suggested. The consideration of these two matters should have precedence of the other three, for upon the answers to the former would greatly depend the necessity for spending much time upon the latter.

Low-Grade Gas and the Unaccounted-for Percentage.

There were several matters of more than passing interest in the Presidential Address of Mr. F. A. West, of Newark, to the members of the Eastern Counties Gas Managers' Association [*ante* pp. 237-240]. In it are found the broad views of a thinker who forms judgment from personal experience and experiment, and is not inclined to attach himself to any particular flock who adopt the practices of those whom they regard as dependable leaders. The members, after visiting the Newark Works and hearing the Presidential Address, have several matters over which to indulge in a little mental exercise for the purpose of examining into, and forming conclusions upon, their validity. But we are confident that, whatever other engineers and managers may think, Mr. West will not shift in any degree from the opinions he has formed as to the best course of procedure in the circumstances with which he is surrounded at Newark. However, we must preface what will be regarded as the cardinal and controversial points of the address by a brief reference to general matters. The Gas Company (whose property is about to pass into the hands of the Corporation) were badly in want of new works; but instead of going to a fresh site, economy suggested the piecemeal reconstruction of the works, until now there is hardly a remnant of the old remaining, although the arrangement may not be precisely what Mr. West would have selected or designed had he been dealing with a virgin site, and so had freedom for the lay-out. He has continued horizontal retorts; and from his method of operating them, he is obtaining a regular flow of gas of even quality. Working 12½ cwt. charges in twelve hours, charging every six hours, and employing temperatures of from 1300° to 1330° C., he is making 72·3 therms from South Yorkshire and Nottingham coal; and, when four beds are at work, the output is equal to 140,000 c.ft. per man per day, for every operation in the retort house—including clinkering furnaces, removing ashes, sweeping-up, &c. No one will be prepared to criticize these results, having regard to the circumstances. So working, and at the temperatures mentioned, it is hoped the settings will have a long life. Absolute control is maintained by routine testing throughout the operations. In this way, troubles are often avoided; and, moreover, a regular supply of 475 B.Th.U. gas is given, of uniform composition and specific gravity. Incidentally, it may be suggested that a useful hint will be found by some engineers in the description given by the President of his coke-handling plant, which was made by a local firm from second-hand steel work from the old retort house.

It is to the controversial part of the address to which we particularly wish to direct attention, because we are confident that there will be dissentients from the views expressed, as well as strong supporters. From his experience with low-grade gas (no lower than 410 B.Th.U.), Mr. West is persuaded that it is uneconomical, and not in the best interests of an undertaking such as that at Newark. He finds that the troubles he experienced through the distribution of gas of that calorific value are disappearing, with economic advantages, by the supply of gas of no higher value than 475 B.Th.U.—only a 16 p.ct. increase. His deductions from the Newark experiences are that, while there are admitted advantages for almost every gas-works in being equipped with alternative methods of gas manufacture, there are also decided disadvantages. He is convinced that in the smaller works it is not an economical proposition to run two different types of gas-producing plant at the same time, as, in such circumstances, the best efficiency cannot be obtained from either. That is true in respect of the smaller works, but, in all industrial works, one has to take into consideration economic efficiency as well as plant efficiency before final judgment is passed in respect of such a question as this. He admits that there is in the auxiliary plant an aid to the control of the local coke market; and, in existing coke market conditions, this advantage is one to which due weight must be given, with, concurrently, other secondary products reduced in value. Any outlet for the profitable utilization of coke is welcome at the present time; and, looking also at developments in competition in the coke market, we are not disposed to belittle this aspect of the matter, having regard to the ultimate economic considerations. There must be regard for the future as well as the present. We also hold that the changing conditions in respect of labour must be kept in view—not so much labour within the industry, but in those industries upon which gas undertakings depend for materials. An obligation rests upon those who have the control of such a supply as that of gas to do their utmost to maintain it in times of emergency as well as in normal conditions. We will not say this is as important as giving constant service in respect of pressure, calorific value, composition, and specific gravity; but it has an importance which should not be neglected, in view of the reliance placed to-day on gas for light, heat, and power. It seems to us that the only point Mr. West has in his favour is the one that two small plants cannot be continually worked each to its highest efficiency. In normal conditions it is not difficult with a water gas or complete gasification plant and a coal-gas plant, if both are under good supervision, to mix the two gases in determined proportions, and so give a supply constant in all respects.

The next point is as to the supply of low-grade gas. Mr. West's experiences have not been good at Newark with gas of 410 B.Th.U.; and he has retraced his steps to 475 B.Th.U., and is much happier in his particular circumstances. He puts the position tersely when he says that, while the low-grade gas was economical to manufacture, it was not the cheapest to sell. What he found was that, as the make went up, the unaccounted-for gas increased in direct ratio until the alarming figure of 20 p.ct. was reached, and there seemed to be no finality about it. So far as the mains are concerned, if they are in sound state, there should not be more leakage with the low-grade gas than with the high grade, unless (with unsound joints) the greater leakage be due to the use of higher pressures with the former. But the fact remains that since the high-grade gas (if 475 B.Th.U. quality is entitled to that nominal distinction) was introduced, the percentage of unaccounted-for gas has in two years been reduced from 20 to 13. This fact the President regards as sufficient evidence to show he is on the right lines. Thermally the loss of 20 c.ft. out of every 100 c.ft. of 410 B.Th.U. gas means a loss of 8200 B.Th.U., while the loss of 13 c.ft. out of every 100 c.ft. of 475 B.Th.U. gas means a loss of 6175 B.Th.U. From the economy point of view the President is right. So far, however, as the distributing system is concerned, we cannot see that there should be a reduction of the unaccounted-for percentage by the mere process of increasing the calorific value by 65 B.Th.U. per c.ft. But there must be a cause for the effects described; and there can be little doubt that the real cause of the high percentage of unaccounted-for gas was the condition which customers' meters attained—after, so we gather, shorter service—during the reign of the low-grade gas. There is no doubt that with low-grade gas there must be complete removal of all impurities which have a deteriorating effect upon the metal parts of meters. The leathers of the meters, too, perished considerably during the years of the supply of the low-grade gas; while the greater proportion of hydrocarbons in the richer gas is having a good protective influence. Those are the points over which there may be discussion between the advocates respectively of low-grade gas and what to-day may be described as the normal grades of gas. And we shall not be surprised to hear of experiences where there has been no undue increase of the unaccounted-for percentage where low-grade gas is distributed. However, technically that is one of the

outstanding features of the address; and in it there is a challenge based on an experience of some duration. But we are not prepared to say that what is stated would apply as conclusive in all local and economic circumstances. It may be that there will have to be greater recourse to complete gasification and lower grades of gas as time passes. No one can yet say positively what will happen; but should that come to pass, then inventive faculties will set to work to defeat such attendant drawbacks as are described in the address.

A highly pleasing feature of the deliverance is the President's firm views on the subject of service. He is a strong believer in supervision not stopping short at the meter, but that it should be carried into the vital quarters beyond. Newark may be classed as one of the pioneers in this. Some years ago the Company obtained an enactment which enabled them to specify the size of internal pipes; and now architects, builders, and gasfitters are all required to work to specification in the piping of houses. Then, again, the undertaking has a well-trained inspector whose duty is to call at every house and inquire if, and see for himself that, everything is working satisfactorily. Mr. West is quite convinced this is an economical scheme, as many small defects are discovered and put right which would otherwise cause the consumer to be dissatisfied. All who take the long and the correct view will agree with him that the general policy of up-to-date gas undertakings should be service to the public, if they are to keep abreast of the times, and meet competition successfully. It is indeed much better to charge a fraction of a penny per therm more for gas, and give thorough satisfaction, than to sell cheaper gas, and not trouble about the consumers realizing good results. Though that fraction of a penny may have, under the sliding-scale, a slight effect upon the dividends of share and stock holders, it is one of the soundest pieces of protection they could have for their capital in these keenly competitive days.

Whatever part of the address is considered, we see in it that the President has one objective to all his doings within the opportunities provided by his environment. It is—Good Service. That should be the predominant consideration throughout the gas industry. It is the highway to maximum progress.

The Industrial Business.

There are indications of a larger activity in the gas industry in connection with the application of gas to industrial operations, and above all a bigger recognition of the fact that, for the best and permanent promotion of this branch of business gas salesmen with special knowledge are required. The "B.C.G.A." have contributed to the promotion of specialization by the formation of a Circle for industrial gas salesmen only; the point as to special knowledge and acumen was strongly emphasized by Mr. Dean Chandler in the remarkably engaging and information imparting paper (published last week) which he contributed to the London and Southern District Junior Gas Association; and the same view underlies all that was said in the paper, which concentrated much, that Mr. C. Bryan Donkin read at the meeting of the Eastern Counties Gas Managers' Association last Wednesday. The largely increased attention which is being given to this subject is very opportune. Industrial depression is fairly rife; there are signs that revival is at hand, but that it is likely to be a progressive revival, and not one which will come upon the country as a rolling tide. The conditions therefore admirably serve as an opportunity for the exploitation of industrial gas heating.

Those in charge of industries are looking around to ascertain where and how they can effect economies; and the gas industry has the means available for assisting in its promotion. But a great deal of care is necessary in treating this matter, because the experiences of gas heating during the war had a twofold effect; and there is need to correct any false impression that may have been formed during that period, and to further the good impressions that were made by being in a position to show the advances that have since been achieved. We get mention of the dual impressions by taking together the papers by Mr. Bryan Donkin and Mr. Dean Chandler. The former states that "during the war, when furnaces were required quickly and in large numbers, there was no time to go into questions of design and efficiency. Consequently users got the impression that gas was an expensive and inefficient fuel. However, very great advances have been made in the scientific design of the gas furnace; and gas can now show efficiencies far greater than other fuels." Mr. Dean Chandler's point of view is: "The use of town gas in all branches of engineering and industrial activity was largely a war-time development. . . . . It was thought in some quarters that the industrial load which had been built up during the war would, after the Armistice, decline and be finally lost; but the advantages of the use of gas as a fuel for a hundred-and-one purposes had been conclusively demonstrated, and its future was thereby assured. Of course, it was to be expected that a sudden drop in the load would occur immediately after the cessation of fighting, but with the return of more normal conditions in industry, the temporary set-back has gradually been made good." Both authors are right. War-time experiences—when all was push and hurry, and time and not cost was the important thing—did give to many men in industry the idea that the fuel cost of gas was high; while others saw the economy and efficiency attributes of gas compared with solid fuel. It is highly important that those controlling industry should get detached from the consideration of fuel costs alone, and give consideration to the economies and higher efficiencies which the change to gaseous fuel produces, and which reduces the over-all costs per unit of production. That is a matter that must be kept well before those concerned in industrial work. Even if fuel costs are considered alone, both Mr. Dean Chandler and Mr. Bryan Donkin show the increased knowledge, compared with the early adventure of gas in this field, that exists to-day as to the points to which strict observance must be given in order to gain higher thermal efficiencies and thus lower the fuel cost *per se*. There is also the question of the correct methods of application, which have a considerable bearing upon fuel cost. There are a right way and many wrong ways of applying gas as a fuel in industrial operations; and that is why a person not fully competent to deal with large propositions may do irreparable harm, through not being able to advise in a manner which will give the consumer the maximum economy. Mr. Dean Chandler supplies an instance of how, by laboratory investigation, the South Metropolitan Company succeeded in proposing an entirely new system for the heating of steel tram wheel tyres, which reduced the consumption of gas, to the L.C.C. Tramway Department, from 0·7 to 0·2 therm per tyre; and another example is given of a development which resulted in a greatly enhanced quality of product.

The papers by Mr. Bryan Donkin and Mr. Chandler contain much information for every gas man who is engaged in the industrial gas business, and they should be read together, and be carefully studied. The subject is one which interests most gas managers, because there is hardly a gas-supply area in which there is not some industry in which gas can be applied. Even villages have now their garages in which motor-car repairs are carried out, and which require heat for the work. The industrial consumer is, as a rule, one whose custom is well worth having; and it can be obtained and retained by gas undertakings by attention to such matters as both authors present in their contributions.

The Thousand Pounds Coke Competition.

Our contemporaries in France, Germany, Holland, and America have published information regarding the coke competition; and inquiries have been made for further particulars from friends abroad. These have been given. The conditions were fully set forth in the "Journal" for Feb. 18; and references to other information which has been sought have since appeared in our columns. We hope all who are working at contributions will remember that the last day for receiving them at this office is June 30. We want as many papers as possible in each of the three sections. A wag asked us the other day who would be the winner of the £200 prize. The members of the Committee will not know who is the winner of that or any other of the prizes until after adjudication of the last of the contributions. Not till then will be opened the sealed envelopes containing the names of the competitors. We might take the

opportunity of mentioning that a paper must only have a *nom de plume* at the top; and the *nom de plume* must be on the outside of the sealed envelope. It would also be an additional safeguard if repeated on the sheet of paper enclosed in the envelope which bears the name and address of the competitor.

Electricity for Gas-Works Purposes.

In the "Journal" for March 18 (p. 662), reference was made to the action of the Ministry of Health in consulting the Electricity Commissioners as to including in a loan applied for by the Goole Urban District Council for gas-works extensions an amount for the provision of electricity generating machinery for plant operation. The Commissioners advised that the Council should take their supply from an electricity supply company. The National Gas Council advised that intervention in such a matter by the Electricity Commissioners should be resisted. We are pleased to learn that the Council have received information that the Ministry of Health has since unconditionally granted the necessary sanction to the Goole Council.

More Capital Wanted.

It is a change to see once more the name of Lt.-Col. E. Eaton, "C.E.," figuring on a prospectus with which 43, Cannon Street, is identified. The Chagford and Devon Electric Light Company, Ltd., require "additional extension capital," and Eaton's name appears on the prospectus in association with the useful baronet—Sir Charles B. H. Soame—and Mr. R. G. Harley as Directors. The perennial officials, Walter Thompson, Solicitor, and Turner & Co., the Auditors, are also there. The Company have opened the mouths of their coffers to wide dimensions. The offer of Chagford and Devon (why should Chagford come before the county?) capital is only for £12,500 of cumulative preference shares of £1 each, for which a premium of 1s. is required; and £15,654 ordinary shares at £1 each, which are entitled to "91 p.ct." of the balance of distributable net profits. Apparently that £28,000 odd will not be enough for the new business to be done at Chagford, as a "limited number" of 7½ p.ct. first mortgage debentures are also waiting acceptance by anyone who is willing to part with his or her money. The Lighting and Power Finance Corporation, Ltd., part of the 43, Cannon Street machinery, are making this offer. A great point is made of the fact that the Company are utilizing water power, and that the Directors have concluded an agreement for supplying in bulk electricity for light, heat, and power. With whom this agreement has been made, is not stated; and no figures are given as to existing business—actual consumption, revenue, profits, &c. A very artful statement is made in a circular accompanying the prospectus: "The possibility of the undertaking being bought out by a larger concern must not be disregarded, in which event considerable capital profit may accrue, and in particular to the ordinary shares, which, after payment out of the yearly net profits of 9 p.ct. to the preference shares are entitled to rank for dividend in the balance of net profits—viz., 91 p.ct." At the top of the prospectus appears the words: "Every application will receive consideration as far as is possible." Of that we have not the slightest doubt. Another copy of the prospectus of the South Midlands and Berkshire Electric Light and Power Company has also been received from a gas shareholder.

Coal Shipments and Values.

In March there was a little more activity compared with February in the coal export trade, but not enough to make those engaged in it any more lighthearted when the figures and prices are compared with those of the corresponding months of last and the previous year. The total quantity exported in March was 4,392,258 tons, while in February 4,344,008 tons were shipped. In the corresponding month of 1924, the amount exported was 5,190,265 tons, and in that of 1923 7,180,102 tons. The values of these quantities were: March, 1925, £4,557,002; 1924, £6,390,574; 1923, £8,817,851. Gas coal shared in the slightly increased activity; the quantity shipped during the month being 600,104 tons, as compared with 568,966 tons in February. The shipments of gas coal in March, 1924, were 687,358 tons, and in 1923, 866,607 tons. The value of the gas coal shipped last month was £603,672, which gives an average per ton of £1 0s. 1·4d., or 5d. less than the average for the gas coal exported in February. Taking the first three months of the year, the total quantity of coal sent abroad was 13,102,317 tons compared with 15,705,950 tons in the corresponding period of 1924, and 18,694,402 tons in that of 1923. Of these quantities in the first quarter of this year, 1,720,846 tons was gas coal. This compares with 1,981,846 tons in the first quarter of 1924, and 2,290,790 tons in that of 1923.

Gas Coke Exports.

There was also rather a better showing in regard to gas coke last month, as compared with February; the respective figures being 52,658 tons and 41,714 tons. In March, 1924, 76,826 tons of gas coke were exported; and in the same month of 1923, 93,865 tons. The value of the gas coke shipped last month was £76,400, which works out to an average of £1 9s. 0·2d. per ton, which is close upon 1s. 7d. less than the average per ton for February. The value of the quantity exported in March, 1924, was £136,708, and in 1923 £144,777. In the first quarter of this year, the total shipped was 158,178 tons, which is rather less than half the quantity sent overseas in the corresponding period of 1924, when it reached 326,455 tons. In the first three months of 1923, the amount of gas coke shipped was 294,553 tons. The values were: For the first quarter of this year, £240,085; 1924, £569,361; 1923, £428,941.

Sulphate of Ammonia Shipments.

Last month the amount of sulphate of ammonia sent abroad was 19,198 tons, as against 26,321 tons in March, 1924. For the first three months of this year, 79,607 tons were shipped, as compared with 87,258 tons in 1924. So far, therefore, we have not succeeded in maintaining the quantity of business done abroad in the first quarter of last year. The best customer up to the present is Spain and the Canaries; the quantity taken by them being 28,699 tons in the first quarter of this year, as compared with 16,439 tons in the corresponding period of 1924. The Dutch East Indies has been the next best customer with 14,474 tons, and Japan follows with 14,182 tons; but last year in the same period Japan bought 32,755 tons.

Coal Tar Products.

In March the export of benzole showed a distinct upward move; the quantity being 53,041 gallons, as compared with 13,246 gallons in March, 1924. But in the first quarter of last year considerably more than twice the quantity was shipped, contrasted with the first quarter of this year; the respective figures being 252,749 gallons and 115,521 gallons. Of naphtha last month, 3463 gallons were sent abroad, as against 4638 gallons in March, 1924. The shipment of naphtha for the quarter was 10,895 gallons, as against 49,797 gallons in the corresponding period of 1924. Taking together tar, oil, creosote, &c., no less than 3,063,280 gallons were sent abroad last month, compared with 2,234,298 gallons in March, 1924. In the first three months of this year, the total quantity exported was 10,828,946 gallons, as against 9,513,748 gallons in the first quarter of 1924.

Gas Oil Imports.

In March 5,721,410 gallons of gas oil were imported, as compared with 3,614,176 gallons in March, 1924. In the first quarter of the year, the total quantity of gas oil imported was 16,250,811 gallons, which contrasts with 16,103,496 gallons in January-March, 1924—a small difference.

Anti-Eczema Soap

As the result of careful research, Messrs. F. & E. Stanton, Ltd., of Lewisham, London, S.E. 13, have been successful in producing an anti-eczema emulsion, and experimental work has enabled them to convert this into a firm, hard, anti-eczema soap, which will not only prevent gas eczema breaking out upon gas workers, but will also cure those who are suffering from it. The firm inform us that they will be pleased to post, free, a 2-lb. sample bar of the soap upon receipt of a post-card from any gas manager or engineer, so that a test may be made of its virtues.

Institution of Civil Engineers.—An Extra Meeting will be held on Wednesday, May 6, at six o'clock, of the various bodies which are co-operating in the work of the Special Committee on Tabulating the Results of Heat-Engine Trials. Mr. J. Carnaghan will introduce the following subject for discussion: "A Standard Code for Tabulating the Results of a Heavy Oil Engine Trial." Capt. H. Riall Sankey, C.B., C.B.E., Chairman of the Committee, will preside.

PERSONAL.

Among recently elected members of the Society of Chemical Industry is Mr. Jacques Abady.

At a meeting on the 21st, Alderman Frederick Joseph West, C.B.E., Lord Mayor of Manchester, was elected a member of the Institution of Civil Engineers.

Mr. Alexander Young, Gas Manager at Tayport, has been appointed Engineer and Manager of the gas undertaking at Bridge of Allan. Educated at Arbroath High School, Mr. Young served his apprenticeship with Messrs. Shanks, of Arbroath. Later he obtained the position of Chief Draughtsman at the Dundee Gas-Works, whence he went to Tayport.

Many readers will be interested to learn that Mr. R. L. Wilson, who has for a number of years occupied the position of Commercial Manager to Messrs. J. Brown & Co., Ltd., manufacturing chemists, of Savile Town, Dewsbury, has been appointed a Director of the Company.

OBITUARY.

In the early part of this month Mr. A. Jacob, Manager of the British Aluminium Company, Ltd., died at Hatch End, Middlesex, at the age of 57 years.

We regret to learn of the death, on the 18th inst., at 93, Morningside Drive, Edinburgh, of the wife of Mr. James O. Scott, of Messrs. Alder & Mackay, Ltd.

ELECTRICITY SUPPLY MEMORANDA.

Some of the circulars issued by electricity supply undertakings regarding electric cooking and heating are probably more interesting to those who understand, than to those who have not the knowledge to estimate, the value received for a given expenditure. We have before us some circulars on the subject sent out by the Great Yarmouth Electricity Supply Department. The first one tells us that in response to an increasing demand from electric lighting consumers who are desirous of taking advantage of electric cooking and heating, the price for current has been reduced to 1½d. per unit (flat rate) for those purposes, or 1d. per unit for all purposes, *plus* a lump payment equal to 20 p.ct. on the rateable value of the premises, *plus* a rent of £1 a year for a No. 19 cooker, 24s. a year for a No. 20 cooker, and 28s. a year for a No. 22 cooker. The householders of Yarmouth who desire to take advantage of electric cooking and heating may find that these processes will take advantage of them. There are two points into which the householder should inquire. One is, Why do the electricity people have to charge 1½d. per unit for cooking and heating, while so much more is charged per unit for lighting? And, Why do they talk about 1d. per unit for cooking and heating under the rateable value system, when there is also the 20 p.ct. in this instance to be divided over the consumption to find the average total cost per unit? They will reply that they want to encourage a day load, and to induce this they charge a low price. But it must be apparent to the poorest of intelligences that if there were the savings and merits about electric cooking that are so lavishly spoken of and circulated, there would be no need for such low prices per unit. The fact is that the potential heat energy in a unit of electricity is so meagre—3420 B.Th.U.—that expediency compels a small charge in order to make any show (even then it is of a remote order) in the competitive field. That is the point to which the attention of householders should be directed—in other words, they should be informed of the modest heat value of a unit of electricity in comparison with the value to be purchased at the same price through other heat agents. That is a matter on which these circulars for the "information" of the householders of Great Yarmouth are as silent as the grave. It would, of course, be a strategical blunder for electricity purveyors to say anything about the matter. What is said is that "the electric method is extremely simple, and requires no previous experience—a point which cannot be too strongly emphasized in view of the misconception which appears to exist in the minds of many people." It is not the method that is extremely simple; it is the householder who believes that it is—for the "simple method" is the seat of several weaknesses, to which it is constantly succumbing to the inconvenience of the user, and which then call for rectifying expert attention. So real is the uneconomy through hotplate inefficiency, and so pronounced are the limitations and the troubles, that we see in the Department's circular that "no stove will be let for a shorter period than twelve months." It is in the circumstances a necessary safeguarding condition.

Yarmouth and the Cooking Load.

Plausible Tales and Incontrovertible Facts.

But we were on price. It is the custom in some areas to trot out consumers' low accounts for electricity for cooking and heating in comparison with gas. It should be pointed out to householders that these are nothing to go by. Such testimony misses out the important factor of work done; the work done must be equal if there is to be any true financial comparison. Householders should also have impressed upon them that a gas therm equals 100,000 B.Th.U., while a unit of electricity equals only 3420 B.Th.U. Therefore 100,000 ÷ 3420 = 29 units of electricity. Any intelligent householder must see when the matter is brought to his notice that—with a slightly higher thermal efficiency in the electric oven than in the gas oven, but with a higher efficiency on the hotplate of the gas-cooker than on the electric hotplate (75 to 80 p.ct. of the work done by a gas-cooker is carried out on the hotplate)—it is impossible, equal work being done, for the electric cooker, in view of the heat value delivered for a given expenditure, to match the gas-cooker for economy. Consumers with these facts before them will realize why in their struggles to secure heating and cooking business the electrical people have to get down to low prices per unit; even then the thermal value given for money expended is distressingly poor. Just as one cannot get out of a jug more liquid than it will hold, so one cannot get more heat out of a unit of electricity than it can generate. But the electricians make out a plausible tale which, without investigation, may deceive many people.

Charges and Costs.

It would be interesting to know how the flat rate of 1½d. per unit for heating and cooking is justified in Great Yarmouth. It is stated that 230 cookers were placed as the result of the Industrial Trades Exhibition held in March last; but the load from these (assuming they are all retained in constant use, which is very doubtful) cannot warrant a price per unit less than the average of the generating costs, let alone the total expenditure, per unit sold. In the year ended March 31, 1924, the current sold for all purposes amounted to 2,094,892 units; and the total cost per unit sold was 2·8d. This was made up as follows: Generation, 1·88d.; distribution, 0·3d.; rents, rates, and taxes, 0·18d.; and management, salaries, printing, stationery, and miscellaneous charges, 0·44d. From this it will be seen that the 1½d. per unit on the flat rate is 0·38d. below the average generating costs per unit, and as much as 1·3d. below the average of the total costs. As to the rateable value system, an illustration will show that in some—perhaps most—cases the revenue per unit will fall short of the average expenditure, although the fixed charge is supposed to cover the standing costs incurred in supplying the consumer. Take a house rated at £50; the fixed charge is to be 20 p.ct. of that, or £10 per annum, which reduced to pence is 2400d. One of the circulars tells us that the electricity consumed for cooking averages 1 unit per person daily. Therefore, supposing there are six persons in a household, this would be 42 units a week. Let us add 8 units a week for lighting and incidentals—seeing that we may be sure the makers of the cookers have not over-estimated the consumption at 1 unit per person a day—this would make 50 units per week, or 2600 per annum at 1d. Adding to this the fixed charge of 2400d., we have 5000d. to be divided by the 2600 units. This works out to 1·92d. per unit. If the householder's consumption is more, it would work out to still less; yet the total charges to which we have referred average 2·8d., and the generating costs 1·88d. This is municipal trading; it is the grossly unfair trading with which gas undertakings are called upon to compete. There is no justification for it. It is also totally unjust to the man who prefers electricity for lighting and gas for cooking. Why should he pay three or four times as much per unit for lighting when the man in our illustration with the cooker can, during lighting hours, both cook and light at a cost of 1·92d. per unit, or 0·4d. above the bare generating costs for the year ended March, 1924. He might be advised to go on to the rateable value system; but would it pay him, with his house rated at £50, if he prefers electricity for lighting only? Flat-rate lighting consumers are, through the revenue they produce, the backbone of electricity undertakings to-day. It is only through their revenue that electricity concerns are able to indulge in these fantastic schemes of making a fixed charge upon rateable value or floor area of rooms (with an additional low charge per unit), instead of upon the actual electrical requirements. However, we may be sure the Gas Company will show the inhabitants of Great Yarmouth that the thermal value supplied by them far exceeds for a given expenditure the poverty-stricken value offered by the Electricity Department.

An Investigating Committee and Domestic Consumption.

A sane and sound electrical tariff to displace the flat rate, with discounts for good loads, is something which, it is admitted in the electricity industry, its men have not yet achieved, despite a wonderful aptitude for arithmetical gymnastics, as instanced in the "Memoranda" last week. There has been a great deal of advocacy of the two-part tariff, of the rateable value form. In

the Act of 1922, power was given to the Electricity Commissioners to supersede the flat rate where they were satisfied with proposed alternatives; but in their last annual report, they stated that very few applications had been made for permission to adopt a new system. Now the Commissioners have appointed an Advisory Committee to report on certain questions affecting the use of electricity and the methods of charging. Allusion is made in our editorial columns to the points which have been referred to the Committee for consideration and report. But here it may be mentioned that the Committee represents various organizations in the industry, and is constituted as follows: Messrs. J. W. Beauchamp (Chairman), S. T. Allen, and A. N. Rye (representing the British Electrical Development Association), Messrs. J. S. Highfield and W. B. Woodhouse (representing the Incorporated Association of Electric Power Companies), Messrs. A. C. Cramb and W. C. P. Tapper (representing the Incorporated Municipal Electrical Association), and Messrs. H. Bentham, F. E. Gripper, and K. A. Scott-Moncrieff (representing the Provincial Electric Supply Committee of the United Kingdom).

The "Safety" of Electricity.

Within a week there were three disconcerting street explosions—at Keighley, York, and Falkirk. At the first-named place an electric cable misbehaved itself not only by fusing, but by melting a gas-pipe. The cable it is stated was twenty years old, and was encased in a cast-iron pipe instead of the usual earthenware conduit as is the modern practice. At both York and Falkirk, the explosions caused manhole lids to make a swift flight in the air, and caused other unpleasant commotion. These incidents appear to be getting more and more frequent; and this suggests that there are towns where a good deal of old distributing material should be replaced by new, laid in the most approved style. Electrical men have dropped talking about town gas leaking into their culverts, because advancing knowledge has taught them that a more potent explosive can be generated by their own systems. From explosions to fires. One was caused in the early hours of last Monday morning at the works of Messrs. Needlers, Ltd., chocolate manufacturers, of Sculcoates, Hull. Coming when the week-end closure had almost expired, the only explanation is electrical fusion; and a curious thing is that it was a man who was on duty at the Corporation electrical power station who, just before two o'clock in the morning, noticed a small flickering flame in the upper storey of Messrs. Needlers' premises. Within ten minutes that small flickering flame became a raging fire owing to the combustible character of the boxes and wrappings in the part of the building where the fire broke out. From fire to failure. Oxford was thrown into partial darkness during the evening of last Saturday week. It would have been plunged into complete darkness had it not been for the fact that the gas undertaking of Oxford flourishes, and it has a good share of the lighting custom. Candles came into temporary popularity.

Compulsory Powers Rejected.

A short time since attention was called in the "JOURNAL" to a Bill which Mr. Harris intended to introduce into the House of Commons for the purpose of increasing the powers of joint electricity authorities. It will be remembered that, when the legislation of 1919 was under the consideration of Parliament, in order to save the Bill, and obtain power to establish the Electricity Commissioners, it was found necessary to delete the compulsory powers. Since then, certain joint authorities have been set-up; but through the want of general agreement in the areas they have not been able to function in the manner originally intended. Some people consider that this is due to the absence of compulsory powers; but as a matter of fact there is a mass of opinion in the industry itself that there should be no compulsion in this matter—that every electricity supply authority should be allowed to take the course which it considers most desirable in the interests of its own undertaking and area. Those who do not concur in this opinion hold that electricity supply should have a national or extensive territorial base. But we have much sympathy with those local authorities who believe that in being pooled, and averaging the costs in respect of generation and transmission, they would not be in such good position as they are by generating for themselves and supplying in a densely-populated area—particularly those industrial in character. Just recently, Mr. Harris moved for leave to bring in the Bill for conferring upon joint electricity authorities the compulsory powers which were deleted from the Bill of 1919. There was a strong opposition to this, which was led by Mr. Austin Hopkinson, whose opinion was that it would be a mistake to do anything which would stereotype the industry and set the dead hand of the State on technical progress. It is Mr. Hopkinson's belief that miraculous changes will in time take place in respect of the methods of electricity generation—in fact, his idea is that, towards the end of the present generation, we shall see the direct production of electricity by the oxidization of coal in some form of carbon cell. He believed that the Bill to confer compulsory powers on the joint electricity authorities would be disastrous to technical progress. The Bill was rejected by 193 votes to 124.

CENTENARY OF THE SOUTH METROPOLITAN GAS COMPANY.

A Volume Worth Preserving.

WHEN, as rarely, people reach a century in life, their friends desire to felicitate and rejoice with them. When large concerns have passed through a century in business, custom prescribes a celebration of the event. Such an anniversary cannot occur again in the lives of anyone associated with the enterprise. Therefore those responsible for the administration of such businesses may be pardoned for indulging in a little celebration and rejoicing, when they may receive from their friends their cordial wishes for continued and still greater progress in the future. In the case of the undertakings of the gas industry (to which we are all proud to belong), there is good cause for congratulation on the ground of past achievement, because they have worked well—not only in times that have been good, but in periods of great tribulation. They have never made a backward movement; they have always gone forward in the development of their businesses, and therefore in public and national service.

The hundredth anniversary of the birthday of the South Metropolitan Gas Company was May 28, 1924; but, through various circumstances, the Directors decided not to have celebrations in connection with the event, but quietly to pass the time as though it was an ordinary occurrence. The decision, however, was accompanied by the resolve to commemorate the completion of the century's work by having a volume prepared briefly surveying the history of the Company, the large expansion of the operations of the concern, and the important part it has taken in the political and technical advance of the industry.

The volume before us is entitled "A Century of Gas in South London." The literary work is good. It is something more than a mere historical sketch. It is so written that it immediately draws one into the life and activities of the Company. It is a book probably rather for the non-technical reader than the gas technician, yet the gas technician who begins to read will want to continue until he has completed the 23 pages of text into which has been compressed a whole century's history of a concern which has ever been adding to its laurels—administratively, technically, and commercially. The illustrations are excellent; and at the end there are a number of portraits of men who have been prominently identified with the Company, and, through the Company and in other spheres, with the gas industry. We shall prize the portraits, because all of them—excepting two—are of men we have known or do know, and whose friendship has been invaluable. We congratulate the Company heartily on the volume.

To return to its literary part. An idea of how the author has managed to present interesting detail in a manner which will appeal to the popular mind, can at once be given. He is dealing with the vast network of pipes under the soil of South London streets; and he says:

> The mains alone are 1340 miles in length; the area under which they spread covers 52 square miles. This network serves about two million people; some 400,000 meters measure the gas which the Company supplies to its customers. We cannot call it a monopoly, even within its own area; yet it maintains an easy supremacy. Its electrical competitor who used to boast that electricity had antiquated gas, can only muster a fraction of its consumers. It is a hundred years old; yet it has not stopped growing. It expands with the population it serves, and develops with the development of industry.

And then we come to a description of the Company's activities. It is pointed out how rigorously gas is tested for its lighting and heating powers, as milk is tested for its fats, so that the Company protects its own customers against the possibility of adulteration. It supplies, in fact, a standard article at a standard price. And then there is reference to the subordinate industries; to the fact that the Company has its own laboratories, both chemical and industrial. It has its own research department, and makes its own gauges and standard burners. It has three chemical works dealing with its own bye-products. It produces 11½ million gallons of tar and 47 million gallons of ammoniacal liquor in a year. Indication is given as to the applications of the products derived from the distillation of coal. Following these impressive facts, are others no less suggestive. The capital of the Company amounts to 9¾ millions sterling; and a regular dividend is distributed to 18,000 shareholders. Some 8000 workers are employed; and yet the Company is untroubled by industrial strife. "In this great organization of workers and capitalists, there reigns profound and perpetual peace, undisturbed even by a threat of hostilities. In this era of industrial unrest, such an equilibrium must be counted remarkable; and the system which has brought it about should be well worth our study."

With such facts in mind, one naturally seeks to know more of the history of this concern; and a page or two later we come into contact with the origin of the Company.

> In 1814 the first gas-works on the South Bank of the river were constructed at Southwark by an enterprising Scot called Munro. These were sold a few years later to the South London Gas Com-

pany, which was in difficulties before 1824, when the struggling enterprise was taken over by some optimists who called themselves the Phœnix Gaslight and Coke Company. With this Company properly begins our story, for in the course of time the Phœnix came to its last roosting-place inside its rival, the South Metropolitan Gas Company.

The Company had a distinct aristocratic parentage; for one of the original proprietors mentioned in the Special Act of 1924 was the great Lord Holland, who, by the way, was a Fellow of the Royal Society, had been Lord Privy Seal, and was to become Chancellor of the Duchy of Lancaster. Among others were the Hon. James Abercromby (afterwards Speaker of the House of Commons), Baron Dunfermline, Thomas Fowell Buxton (a leader in prison reform and anti-slavery), John Petty Muspratt (a Director of the East India Company), and Charles and David Barclay and Frederick and Charles Perkins (presumably the brewers). Thus the Phœnix Company began strongly; and it had, besides, a five years' start of its rival, the South Metropolitan Gas Light and Coke Company, which was founded in 1829. The latter Company, unlike its other competitors, gave the river a wide berth, and chose for the site of its operations 3 acres of land along the Grand Surrey Canal on the eastern side of the Old Kent Road. There, by 1833, the works were completed, and thenceforth began a long and stern fight between the two companies, to end inevitably in amalgamation.

It is noteworthy, in view of the practices of to-day, to remark that:

> The South Metropolitan Company started operations in the good resolution to supply the public with a pure article, and to that end built a purifying-house which was a model of all that such a house ought not to be. Its windows were glazed; there was practically no ventilation; and it is surprising that it lasted so long as until 1836, when it was completely destroyed by an explosion. In its determination to make good gas, the Company used only cannel coal; but the high cost of this raw material forced up the price of the finished article to 11s. per 1000 c.ft., whereas the Phœnix Company was selling its product at 9s. In 1834, the South Metropolitan Gas Company was proudly informing the world that "the purity and illuminating power of our gas are such that 3000 c.ft. will burn as long and give as great a light as 5000 c.ft. of the gas of the Phœnix or any other Metropolitan Gas Company."

With competing companies in the area, the South London supply suffered greatly through its roads being constantly torn to pieces, as well as through plumbers and gas fitters advising innocent householders to take one company's gas or another as their interest in gas fitting and public lighting prompted them. The public suffered, until at length, in 1853—mainly through the policy of Mr. Thomas Livesey—a general peace was concluded, defining the sphere of influence of not only the South Metropolitan and the Phœnix, but of a later competitor, the Surrey Consumers' Gas Company. This "districting agreement," as it was called, shows that here as elsewhere the Company was in advance of the State; for, although the advantages to the public were enormous, it was some years before the House of Commons could be brought to consent to give it statutory sanction. The agreement was the beginning of a movement to amalgamate the various companies which divided South London between them. The first step was taken by the Phœnix Company, which approached the Board of its principal rival in June, 1870. On July 1, 1879, the Surrey Consumers' Company handed over their premises; on Jan. 1, 1880, the Phœnix Company came in with its works at Bankside, Vauxhall, and Thames Street, Greenwich; and in 1885 the two small Woolwich companies became part of the large concern. Thenceforth the South Metropolitan Gas Company held undisputed sway over practically the whole of what is now London County south of the Thames (except only two small areas)—a territory of 52 square miles, stretching from Abbey Wood in the east to Tooting in the west; and from the banks of the Thames southwards to Streatham and Bromley Hill—a densely populated area containing approximately two million people.

The volume gives an insight into the legislative restrictions which were imposed upon the Company. But despite these, and the competition of electricity, the Company, strong in its position and its resources, has triumphed both technically and commercially in the manner already indicated at the commencement of this review. Its history is interleaved—perhaps more than is the case with any other concern—with the legislative, technical, and administrative progress of the gas industry. The great record which it holds in connection with developments in legislation during the time of Sir George Livesey—particularly in respect of the sliding-scale—is matched by the many important technical developments which have been made in engineering (as witness the 12 million c.ft. gasholder), and through its chemical, physical, and research laboratories during the more immediate years. The history, too, of the Company cannot be referred to without allusion to the great strike which accompanied the introduction of profit-sharing by the Company, which has since developed into real co-partnership in administration, participation in profits, and stockholding by the employees. It was a great innovation, and the example, followed by many other gas companies, has given to the industry an incomparable place in respect of labour in the industrial world.

From the momentous year of the birth of profit-sharing or co-partnership in the industry, there has not been as we know, and as the volume before us states, "even the hint of serious trouble with the Company's workmen." How much under the co-partnership scheme the men have received in actual money since its inauguration is not stated; but the fact is on record that the stock of the Company held in the name of the workers amounts to-day to between £400,000 and £500,000. In this connection we should like to quote two or three passages from the volume:

> One result of the scheme was to give the industry freedom from industrial disputes; another was to induce every workman to take an interest in the success of the undertaking. Before he had been merely an employee, now he was a partner, and an increase of sales or an economy in working assumed a new and personal aspect. The public felt the change in the zeal of the outside staff; the engineers in the zest of their artisans. But there were other and higher advantages which showed themselves as the policy developed. Out of co-partnership grew a corporate sense, an administration in which all shared, and by which all were educated in mutual help and brotherhood. A Co-partnership Committee grew out of the joint interests of employer and employed. It consists of about seventy representatives—half elected by ballot of the co-partners, and half of officials nominated by the Board of Directors. The Committee meet every month, or more often if required; and the week before the meeting the workmen's half of the Committee hold a preliminary conference to consider matters they desire added to the *agenda*. As every department is represented, there is a channel through which every employee can ventilate his troubles, and on the side of the management there is a channel through which their ideas can reach the employees. "On the one hand," says Dr. Carpenter,* "we have difficulties, troubles, modifications, suggestions, proposals, recommendations, as the case may be—all flowing from the workpeople through the Committee to the management; and from the management information of all kinds which it desires to disseminate among the workpeople as a whole. The Committee is, in fact, a small-scale Parliament of Labour, with business-like habits and a directness of action which would do credit to its prototype." Such a body is well equipped to smooth out differences before they reach a danger point.

The centenary volume also gives an account of the large, but unobtrusively performed, war work of the Company; and we read:

> In these days when our industrial system is being attacked as decadent and obsolete, such a record as this might serve to answer its critics; and it might be noted for such an argument that these achievements are not the work of an impersonal thing called Capital (although Capital on a great scale was a prime necessity of the undertaking), but of men, or rather of a line of men, who did not exploit, but rather led, labour in the conquest of an element of Nature. The record proves that the brains, courage, and experience of the employer are essential to the success of an industrial enterprise. We have seen how the line of Livesey began in the childhood of the Company; how Thomas Livesey established the greatness of the Company which his son, George Livesey, developed. But the record would not be complete without at least brief mention of the successor of these two men, Dr. Carpenter, who was Engineer of the Company when George Livesey died, and who is now its President and Chairman of Directors. On the death of George Livesey, Dr. Carpenter led the co-operative movement which gave industrial peace to the enterprise; he directed also the work of scientific investigation, in which he himself took the principal part, and created the machinery of research and experiment. There is hardly a leading improvement in the carbonization of coal and the production of gas in which the two Liveseys or Dr. Carpenter are not, in some way or other, connected. And the practical results of these researches, by the generous policy of the Company, have benefited not one enterprise only, but the whole gas industry.

Interest in the volume is maintained to the very end, and that end is compressed into the following passages:

> The carbonization of coal is obviously of vast importance to our national economy since its heat energy is resolved into useful forms with a much higher degree of efficiency than in the production from coal of steam and electricity. It is therefore not unlikely that our industrial development in this country will go along these lines, and that, by the scientific carbonization of our magnificent coal resources, we shall keep our place in the race against competitors who have the advantage in water power. In this national development, the South Metropolitan Gas Company has played an important part. The names of Livesey and Carpenter are associated with almost every process of the industry; and the Company has also led the way in the achievement of something no less important than gas production—peace between Capital and Labour. It has grown with its territory of South London; and at the end of a hundred years, it is entrenched in every road and installed in every house, and thus inextricably connected with the lives of the two million people it serves. This is so strong a position industrially and territorially that the Company, with its great record in the past, has good title to look forward with confidence to the future. Incidentally, it proves that what is called capitalistic enterprise is neither effete nor selfish, that it may live at peace with its workers, and may serve without exploiting its public.

The volume contains a considerable amount of interest concerning a Company which has had such conspicuous part and place in the making of history in our industry.

* "Industrial Co-Partnership," by Dr. Carpenter; 3rd edition, p. 47.

EASTERN COUNTIES GAS MANAGERS' ASSOCIATION.

HALF-YEARLY MEETING AT NEWARK.

THE first meeting of the Association to be held in Newark took place last Wednesday, when the members attended in very satisfactory numbers to do honour to their President, Mr. F. A. West, who is Engineer, Manager, and Secretary to the Newark Gas Company. The day was full of interest and enjoyment, as also was the visit to Chesterfield on Thursday.

The day opened with the reception of the members by the President at the gas-works, where they were able to see for themselves much of the good work that Mr. West has been, and still is, doing for his undertaking.

At the Gas-Works.

In anticipation of the visit, an illustrated booklet containing a history and description of the works had been prepared by Mr. West, from which the visitors gleaned much information. The Newark Gas Company was formed in 1832, and the original works were built by Mr. James Malam. The site of the present works, which is adjoining the original works, was purchased in 1883, and a new works constructed by Mr. T. Hawksley. The site is divided by a public roadway; the manufacturing and purifying plant being on one portion, and a holder and the distribution department on the other. From Jan. 1, 1924, the Newark Corporation took-over the undertaking; and the transfer will probably be completed this year.

A branch siding has been carried into the works from an adjoining L. and N. E. Railway coal siding. All the coal is obtained by rail; the trucks being shunted direct into the siding by the Railway Company. The coal is simply discharged from the trucks by bottom or side doors into an underground hopper, which discharges into a four-roll breaker, and elevated by a 20-ton an hour bucket elevator on to a band conveyor, which discharges into the overhead hopper in the retort house. This hopper holds about 24 hours' supply. A by-pass shoot has been arranged in the breaker pit to by-pass small coal which does not require breaking, and a two-way shoot has been constructed at the top of the elevator, so that in the future coal can be discharged on to conveyors for trimming coal into stores. The coal stores adjoin the retort house. Provision is made for about one month's winter requirements, half under cover and half in the open.

The carbonizing plant consists of four beds of eight retorts (Drake's settings) arranged in four tiers, with a blank arch for future extensions. The retorts are 23 in. by 16 in. by 20 ft. long, and arranged with 7-in. ascension pipes both sides of the beds. The dip-pipes are fitted with Cort's anti-dip valves; and the hydraulic mains are separate and fitted with the ordinary tar towers, each side of the bench. The foul mains, which are 18-in. diameter, converge into one common main at the end of the beds; and a Cowan retort house governor regulates the vacuum on the retorts. Charging and discharging the retorts is carried out by a Guest-Gibbons combined machine.

Hot coke is removed by a side-tipping wagon running on rails and hauled by an endless rope and electric motor. This is controlled by a tramway-type controller in the retort house. After it is quenched, the coke is drawn up an elevated gantry, and the wagon automatically tips either into the coke bunker or at any desired spot in the yard. Another transporter running at right angles, and electrically driven, conveys coke from the bunker to railway wagons. This transporter is also used for storing coke when required.

There are 750,000 c.ft. water-tube condensers, fitted with 18 in. connections. The exhauster house contains two sets of exhausters—one 50,000 c.ft. per hour by Messrs. Bryan Donkin, and the other 40,000 c.ft. per hour by Messrs. Geo. Waller & Son. The exhausters are direct coupled and steam driven. There are also two Evans ammoniacal liquor pumps for circulating the liquor round the works, and an Evans reversible tar pump for filling tank wagons at the sidings. There are two tower scrubbers 40 ft. high and 10 ft. diameter, filled with wood boards on edge. One is used with ammoniacal liquor, and one with clean water. There is also a Livesey washer, with a capacity of 1 million c.ft. per day.

The purifiers consist of eight boxes: Four small water-lute purifiers 10 ft. by 15 ft. (worked as two, the gas dividing into two streams); two luteless boxes 20 ft. by 15 ft. (all under cover, and worked by a patent Saddler-Cockey centre valve, allowing one, two, three, or four boxes to be in operation at once); and two boxes in the open, 25 ft. by 25 ft. by 5 ft. 6 in. deep, operated by a Weck valve, at present acting as catch boxes. Ultimately there will be added two more purifiers of the same capacity, to form the main purifying plant, with the two smaller luteless purifiers used as catch boxes. The method of working is the backward rotation system; all the boxes being in operation. The oxide in the larger boxes is changed once a year, and put in the boxes in one layer only. The portable oxide disintegrator is capable of dealing with 2 tons of oxide per hour, and is direct driven by an electric motor.

The station meter is a Venturi meter by Messrs. Geo. Kent, Ltd., and has a capacity of 60,000 c.ft. per hour. The town governor is housed in the same building, and is an 18-in. governor, made by the Gas Meter Company. The building also contains all the works gauges, recording and direct reading, the recording calorimeter, &c.; the general arrangement making a central control room.

The water gas plant house contains two sets of Tully plant, each of 300,000 c.ft. capacity. One is fitted with a carburettor for lightly carburetting with oil; Hodges steam turbine blowers in duplicate are used for the air blast; and there are two circulating pumps and a vertical Marshall steam engine, for driving the elevator, in the engine house adjoining. Two scrubber condensers and a Livesey type washer are used for cooling and washing the gas.

The tar and liquor well is constructed at the end of the retort house; and an overhead cast-iron tank is used to store tar. A tar dehydrating plant was erected out of old material on the works, and is very simple and efficient. There are three holders—No. 1, 530,000 c.ft. capacity, with flying lift; No. 2, 175,000 c.ft. capacity; and No. 3, 100,000 c.ft. capacity (the relief holder for water gas).

There are two Lancashire boilers, adjoining the engine house. They are 7 ft. diameter and 27 ft. long, fitted with Wilton forced draught furnaces. The boiler house is equipped with a Lassen and Hjort water softener, two boiler feed pumps, and a feed water heater. The electric generating plant adjoins the boiler house and exhauster house, and consists of one 16 KW. set, direct coupled to a "National" gas engine; and one 25 KW.

COKE HANDLING PLANT.

set, direct coupled to a vertical compound Sisson engine. In this room is also housed a small Bryan-Donkin compressor for atomizing a suitable paraffin for naphthalene. There is a pan-breeze washer of a new type, very simple and effective, operated on the flotation principle, and made locally by the Midland Iron-Works Company, Ltd.

A fully equipped laboratory has been provided; and there are meter repairing and fitting and stove cleaning shops.

Town water is used in the condensers, and then passed to a water softener, after which it is used in the boilers. A well in the works supplies the water for quenching coke; the waste being recovered and employed over again. This water averages 60° hardness, and is not suitable for boilers.

The offices are at the works. A new showroom has recently been opened in the Market Place. A full assortment of appliances is on view, and consumers have proved that they fully appreciate the convenience of a central showroom.

Luncheon.

Subsequently a move was made to the Clinton Arms Hotel, in the Market Place, where the visitors were the guests at luncheon of the Chairman and Directors of the Newark-on-Trent Gas Company. Between fifty and sixty sat down, under the chairmanship of Mr. O. Quibell, F.C.S., J.P. (the Chairman of the Company). He was supported by the majority of the Directors and of the members of the Town Council, who, as already stated, have agreed to take over the undertaking. Among the members of the Association, many old friends were found; while the visitors included Mr. Walter Dunn (Secretary of the Institution of Gas Engineers) and Mr. W. M. Mason (Manager of the British Commercial Gas Association). After the honouring of the Loyal Toast,

The Chairman said it was a great pleasure to him, on behalf of the Directors of the Newark Gas Company, and of the Committee of the Town Council (who would manage the gas-works when they had taken possession of them), to welcome the Association to Newark. The pleasure was all the greater in view of the fact that Mr. West was their President. The members probably knew and appreciated Mr. West as much as they in Newark did. The Directors felt that they were under a great debt of gratitude to him. It was a fact that if gas undertakings prospered, then the communities they served would benefit from their prosperity. He had been looking over the old minute books of the Company, and found that they started with a capital of £5000, and that there were then eleven Directors. There was a minute proposing that the price of gas should be reduced from 10s. to 8s. 4d. per 1000 c.ft.; and a year or two later the contract price for coal was 8s. and 9s. per ton. The sum of £11 was received for a year's supply of ammoniacal liquor; and following this, £15 a year for seven years. The firm with which he had been connected had had the contract ever since then, with the exception of one year. Another item he came across was: "Unpalatable as the contents of this report must necessarily be, there are no grounds for discouragement. Uninterrupted prosperity is not the portion of any human institution." Again—and this was after the Directors had held several meetings to discuss various improvements needed at the works: "The Committee, acting in the same cautious spirit, have avoided laying-out any money in improving the works."

Mr. W. W. Townsend (Colchester) proposed "The Newark Gas Company—Our Hosts To-day." He remarked that the gas industry had to meet acute competition, even in connection with the tarring of roads, and it was necessary for them to consider how best to meet the competition of various road compounds. It was a great pleasure to come to Newark, and they all felt that it was well worth while, if only for the visit to the works. He believed it was the first time the Association had been to this interesting old town. It was rather in a corner of their district, but the members had assembled in big numbers to do honour to their President. They had been much struck by what they had seen at the works. In fact, he himself did not remember to have seen a better works of the size. Mr. West had had a great deal to do with carrying out the various alterations, which revealed much originality. The Town Council were acquiring a works which were well equipped in every way.

The Chairman suitably acknowledged the toast.

THE BUSINESS MEETING.

The business meeting was subsequently held in the hotel—the President in the chair.

Confirmation of Minutes.

The President said the first item on the agenda was the confirmation of the minutes. These had been published in the Technical Press, and in accordance with custom would be taken as read.

Their confirmation was agreed to.

Letters of Regret.

The Hon. Secretary (Mr. W. H. Mainwaring, of Lincoln) announced the receipt of several apologies for absence. Mr. J. Ferguson Bell had written regretting that he could not attend, as he was busily engaged in connection with the impending meeting of the Institution of Gas Engineers.

Government and the Electricity Supply Industry.

The Hon. Secretary said he had received from the Manchester District Institution of Gas Engineers a copy of the following resolution passed by them at their last meeting; and they asked the Eastern Counties Association to endorse it.

> "Having regard to the national importance of the gas industry, and particularly to the service it renders in conserving the coal supplies of the country, this meeting views with concern the reported proposals of the Government for financial assistance for the electricity supply industry, and urges the National Gas Council to take such steps as will ensure the full consideration by the Government of the claims of the gas industry, and suggests that all undertakings should be advised at some opportune time to appeal for the support of Members of Parliament representing the districts within their area of supply."

The President remarked that, as they were all aware, the National Gas Council had this matter in hand, and were doing excellent work; but he did not think it would do any harm if the Association passed this resolution.

Mr. R. G. Shadbolt (Birmingham) said he would like to propose the adoption of this resolution, as in this way they would be strengthening the hands of the National Gas Council, who were fully alive to the situation. Only that morning he had come across the following reference in a newspaper:

> "Speaking at Dovercourt, yesterday, Mr. Moore Brabazon (Parliamentary Secretary to the Transport Ministry) said he was the Minister charged with electricity. The Government were giving the question serious consideration, and, while not promising a land flowing with milk and honey, would do their best to make it a land flowing with volts and amperes."

The members might rely upon it that the National Gas Council were doing their best to put matters in the right light.

Mr. J. Wilkinson (Nottingham), in seconding, said he would like for a moment to refer to another aspect of the question which he did not think had been appreciated by the gas industry as a whole. This was that the electrical industry generally was able to purchase its fuel at a very much lower price, grade for grade of fuel, than the gas industry. He did not know why it was, and he must confess that he was astounded to find such a state of affairs existed. How was it that the electricity industry was able to purchase a 2 in. by 1 in. nut at from 4s. to 7s. per ton less than the figure at which the gas industry was able to procure a similar coal? The only explanation the colliery company could give was that the coal was from a different seam. But it was costing the colliery company just as much to produce. For the last two years, or even longer, the electrical industry had been able to purchase fuel, similar to that of the gas industry in grade, though possibly from another seam, at from 3s. to 5s. a ton less than the gas industry had paid.

The resolution was agreed to.

An Employment Register.

The Hon. Secretary next announced the receipt of the following letter from Mr. W. T. Dunn, the Secretary of the Institution of Gas Engineers.

> At the last meeting of the Council, it was unanimously resolved that there should be established in connection with the Institution a register for the assistance of those members of the Institution out of employment.
>
> I was directed to convey to you this information, with a view to your kindly informing all your members of the fact, so that the register may be of real use to those for whose benefit it is intended.
>
> The Council will greatly appreciate the assistance of your Association in this direction.

As Mr. Dunn was present, perhaps he would kindly explain the proposal to the meeting.

Mr. Walter Dunn said the Council of the Institution of Gas Engineers regarded this as a very important matter. They desired that the Institution should be of the greatest possible value to the members. This proposal, he thought, would meet with general approval. Of course, the scheme was intended for members of the Institution. Naturally, those who joined the Institution and supported it with their contributions were those who should benefit from any movement of this kind. The register was not intended for those who wished to improve their present position, but for those who were actually out of employment. The question was how best the Institution could help such members. They might do it in various ways with the assistance of the members themselves. Many members would know of appointments becoming vacant, and might be kind enough to advise him of the fact. For a long time he had kept a register of those out of employment; and if they could be provided with appointments, the Institution would be doing a real service.

Mr. J. Wilkinson remarked that this was a serious attempt on the part of the Institution to help those who, through no fault of their own, found themselves out of employment.

Mr. P. D. Walmsley (Great Yarmouth) said he was in the fullest sympathy with all that had been said in this connection. Every assistance should be afforded to members who, from causes perhaps outside their own control, found themselves temporarily out of employment. It was very desirable that the Institution should recognize this as one of its duties to its members; but there was a very important reservation he would make. Without going into any further details, the members of the Institution must recognize that there were from time to time certain members who were, through their own fault, in the ranks of the unemployed. Not one of them had any desire to hit a man when he was down; but, without saying more, he submitted that it would be very dangerous to let the idea go forth that, because a member had his name put on such a list, this was tantamount to the Institution guaranteeing his integrity and suitability for a position for which he was an applicant. It was a delicate subject; but he trusted members

would appreciate his meaning, and accept his remarks in the spirit in which they were made.

Mr. Dunn replied that the Institution would not accept responsibility in regard to any member whose name might be put forward for an appointment. His *bona fides* would have to be inquired into by those contemplating employing him.

Wembley.

Mr. W. M. Mason (Manager of the British Commercial Gas Association) addressed the meeting on the subject of the forthcoming Gas Exhibit at Wembley. The decision to take part in this year's Exhibition was, he said, come to after the fullest consideration by a thoroughly representative meeting; and the main thing which weighed with the members present at the meeting referred to, and which had continued to weigh with the leaders of the industry, who had practically unanimously agreed to go on with Wembley again this year, was the competition of electricity. There was electrical competition going on all over the place. If it was straight competition, however, it would be all right; but it was backed by the chief political parties. This meant that the gas industry was at stake, and that it absolutely must pull together and subscribe together. If the politicians and the electricians had their way, there would in time to come be no place at all for the gas industry. It was essential that they should present a united front. The Eastern Counties, as a district, were doing splendidly; but they could do still better if all, big and small, united to this end.

New Members.

On the proposition of Mr. R. J. Calderwood (Spalding), seconded by Mr. R. Wardell (Peterborough), the following were added to the roll:

Members.

Mr. A. O. Snell, Maldon.
Mr. R. Bowden, Lincoln.

Associate Member.

Mr. A. J. Underwood, Showroom Manager, Braintree.

Annual Report and Accounts.

The President remarked that the annual report and balance-sheet had been circulated among the members, and were submitted by the Committee for adoption, with a recommendation that five guineas be paid as a donation to the Benevolent Fund of the Institution of Gas Engineers.

The report and accounts were adopted, on the motion of Mr. J. H. Dougall (Boston), seconded by Mr. G. A. Mallett (Ipswich).

Presidential Address.

Mr. West then delivered his Presidential Address, which will be found on pp. 237-240 of the "Journal" for April 22.

Mr. W. W. Townsend (Colchester) proposed that the best thanks of the Association be tendered to the President for his most interesting and illuminating address. He had taken a very wide sweep, and had given them food for thought in many directions. On the whole, there would be agreement with the arguments he had advanced. The address, and their visit to the works, revealed Mr. West as a thoroughly up-to-date gas engineer. The simple, quiet, and effective coke plant introduced by Mr. West at the gas-works must have struck many of them. He was also to be congratulated upon the even chart he had produced of the gas sent out. The admirable and well-equipped showroom in the Market Place showed, again, that the undertaking was alive to its responsibilities, and to the need for showing the public what could be done with the aid of gas.

Mr. Shadbolt said he would like to second the vote, for the reason that he had personally known the Newark gas undertaking for the last thirty years, and had seen it progress from a very backward condition to the excellent position it occupied now. The circumstances when Mr. West took up his appointment at Newark were abnormal in many respects; and these abnormal conditions accounted for many of his difficulties. The President was one of those optimists who were so necessary to gas administration at the present time. Certainly there was every reason for them to be optimistic, when they took into account the vast possibilities of their industry. The President was well equipped in every way to deal with the problems that confronted him; and they would be doing less than their duty if they failed to record their hearty appreciation of his services both to the Association and to the industry.

The President expressed his gratification at the kind way in which they had received his address, and at the nice things that had been said about him. It was a difficult thing to write a presidential address; but he had felt for some time that they were as an industry very much inclined to leave things to the National Gas Council, the "B.C.G.A.," and the various other organizations. If each one would strive his utmost to help in the good work, not only by giving subscriptions, but by "doing his little bit" in his own way, it would be much to the good of the industry. As an industry they must stand together as firmly as possible. They had to fight, and fight hard; each one must do his share of the fighting.

Gas for Industry.

Mr. C. Bryan Donkin (an associate member of the Association) read a paper on "Gas for Industry." This will be found on p. 312.

New Office-Bearers.

The following office-bearers were next elected:

President.—Mr. Frank Prentice, Ipswich.

Vice-President.—Mr. J. B. Hansford, Bedford.

New Members of Committee.—Mr. H. C. Smith, Tottenham; and Mr. E. W. Smith, Chelmsford.

Auditors.—Mr. G. A. Mallett, Ipswich; and Mr. W. S. Venner, Brentwood.

Hon. Secretary and Treasurer.—Mr. W. H. Mainwaring, Lincoln.

Mr. J. W. Auchterlonie (Cambridge), proposing Mr. Frank Prentice as President for the ensuing year, said they were all extremely pleased that this gentleman had at last consented to take office. In honouring him, the Association would be honouring themselves. Mr. Prentice had occupied a very prominent position as Chairman of their Regional Council, and in that work had given great satisfaction. That he would do equally well as their President, all were firmly convinced.

The motion was seconded by Mr. H. G. Ruggles (Leighton Buzzard), and carried with acclamation.

The Hon. Secretary and the Auditors were heartily thanked for their services; the President remarking that the success of the Association depended more upon the Hon. Secretary than anyone else. Mr. Mainwaring devoted a tremendous amount of time to the work.

Place of Next Meeting.

It was agreed to leave the Committee to determine the place of next meeting.

Representative on the Institution Council.

On the proposition of Mr. S. Hands (Sleaford), the President (Mr. West) was elected to represent the Association on the Council of the Institution of Gas Engineers.

This concluded the business, and the members and friends thereafter took tea together.

ANNUAL DINNER.

In the evening members and guests assembled in goodly numbers in the Clinton Arms Hotel, where the annual dinner took place. The President was in the chair, and was supported by Directors of the Gas Company, by the Vice-President (Mr. F. Prentice, of Ipswich), members of the Committee, and several Past-Presidents. The Mayor of Newark (Councillor W. K. Clarke) was there, with Alderman L. Priestley (the Chairman of the Corporation Gas and Electricity Committee), and other prominent townsmen; and so also were Alderman J. Clark, J.P. (of Chesterfield), Mr. W. T. Dunn, and Mr. W. M. Mason. A thoroughly enjoyable evening was spent in toasting, music, and song. The Loyal Toasts having been honoured at the call of the President,

Mr. J. C. Kew, M.B.E., J.P. (a Director of the Newark-on-Trent Gas Company), submitted "Success to the Eastern Counties Gas Managers' Association." He understood that the President earlier in the day had given them some very good advice on the value of advertising; and he wished to reinforce this advice, because he was sure they would benefit if, in the towns and cities from which they came, they used the local Press in order to advertise their commodity. In the fight which they were waging against electricity, they would have to take all possible steps to make known the virtues and the capabilities of the product which they were so excellently providing; and—speaking, as he did, as a newspaper proprietor—he had no hesitation in saying that they could not do better than utilize the columns of the local Press. His only fear was that when the Newark Gas Company were taken over by the Corporation, it might be thought that the time for advertising was past. He hoped that this would not be so, and that the new owners would take to heart the advice of the President in this respect. It was his pleasure to couple with the toast the name of the President; and if he were to say all he could say, all he ought to say, and all Mr. West deserved, he would keep them listening a long time. In their President they had a very able gas engineer—one whose qualities were many-sided, who had made his name in Newark, and who had rescued the gas-works from a very derelict condition and brought them into a state of considerable efficiency. As Directors, they had great confidence in Mr. West; and they felt that they had cause to be grateful to him for remaining in Newark. The reason must be that Mr. West, having started to "put their house in order," to reconstruct the works, and to bring the undertaking into a state of the highest efficiency and dividend-earning capacity, wished to see the work finished before he passed on. He hoped that under the new ownership Mr. West would find himself on "a bed of roses," and that Newark would succeed in retaining his services for many years to come.

The President, in response, said the Association, in common with the other District Associations, played a very important part in the organization of the gas industry, and were undoubtedly of help to the parent Institution as well as to the various engineers who were members and to the undertakings they represented. He well remembered many years ago the new manager of a very small works coming over to where he (the President) was engaged, to gather some information. It was a wet day, and he took off his coat and placed it on the governor, thereby affecting the pressure. He was told about it, and he said: "I have not got a governor. What I want to know is whether you push or whether you pull." If that gentleman had been a member of one of these Associations, he would probably have got more information in a very short time than he could easily have assimilated. The Association had been very successful in the

past, and he hoped that it had very many years of usefulness before it. Certainly, it was very gratifying to reflect that they had still three of the original members with them—Mr. H. Wimhurst, of Sleaford; Mr. J. Barton, of Peterborough; and Mr. E. J. Brockway, of Cleethorpes—and he hoped they might long be spared to remain members. This was the first occasion on which Newark had been honoured with a visit by the Association; but he hoped that the Corporation, as the new owners of the gas undertaking, would one day entertain them again, when the cycle of works in the area had been completed.

Mr. F. Prentice proposed "The Newark Gas Company," and coupled with the toast the name of Mr. W. A. Ferrier, one of the Directors. One of the most amazing things, he said, connected with the gas industry was the success which attended it—and this in spite of its "enemies," electrical or otherwise. Perhaps electricity had been rather a friend to them, because it had awakened them and increased their efficiency. As a matter of fact, electricity and gas should run hand in hand; for there were things that electricity could not do advantageously which gas could, and the exact opposite was also the truth. A vivid illustration of the extraordinary vitality of the industry, they had before them in the Newark Gas Company. Under the wise administration of the Board, and more particularly under the skilful management of their President, the undertaking had made remarkable progress. In one respect especially he wished to pay tribute to Mr. West. He had seen a good deal of him in London in connection with some of the national organizations, and his wise judgments and sane counsels were always highly appreciated. He ventured to think it would not be very long before the President made a mark in the industry of which they would all be very proud.

THE HUMAN ELEMENT.

In the case of gas companies it was of vital importance to deal fairly and justly with three sets of people. First came the consumer. It was of supreme importance that consumers should be satisfied and contented; and some of them, as they well knew, were not. Then one of the main qualifications in these days for a gas engineer was to know how to handle men. The working men of to-day were getting more and more difficult to handle; they needed almost a special study. It must be remembered that the men were being bombarded by fantastic nonsense, which was poured into their ears by agitators whose very existence depended upon the gap which existed between employers and employed. If he himself had the appointing of an engineer to a works of any importance, the question to which he would first endeavour to secure an answer would be, not how many examinations he had passed, not what letters he could put after his name, but if he knew how to handle men. ["Hear, hear."] This knowledge was an invaluable asset to a gas engineer, without which all the skill in the world was of little avail. Thirdly, there was the shareholder to consider. From the limited observations he had been able to make of the working of the Newark Gas Company, it seemed to him that they had succeeded in dealing fairly and justly with these three important sets of persons.

Mr. W. A. Ferrier, replying, said all who had seen the works would realize how greatly indebted to Mr. West the Company were; and, speaking for the Directors, he could say they did not feel at all ashamed of the state in which they would be handing over the works to the Corporation. Thanks to Mr. West, they were in the high state of efficiency which had been so flatteringly referred to during the day. The ability to understand human nature was one of the main things that led to the success of any business. The initiation in Newark of a system of inspection for each individual householder had been followed by a great increase of business; and the demonstration showroom had been a wonderful success. By paying attention to little things, much satisfaction was given to the consumers. The Company had been prompted to enter into negotiations with the Corporation for the sale of the undertaking by the feeling that public utility concerns should be in the hands of the local authority. There had been ambitious ideas regarding the introduction of electricity; and he hoped that when the present state of suspension passed away, the supply of electric current in bulk to the town would enable the Corporation to give a good service of both gas and electricity with the staff which was now in existence, thus enabling them to operate the two undertakings at a minimum cost, to the advantage of the town. This he would say to the Corporation: "Retain, if possible, the services of Mr. West." ["Hear, hear."]

Mr. Thomas Glover, C.B.E., M.Inst.C.E., proposing "The Town and Trade of Newark-on-Trent," said they were all conscious that they had met that day in a very interesting and ancient town; and at the same time they felt that they were in not only an historic town, but one which was modern in regard to its industries and its trade. For nearly 400 years Newark had had a charter of incorporation. They were honoured as an Association in having with them his Worship the Mayor, Alderman Priestley, and others.

The Mayor, in acknowledgment, said that though the town progressed slowly, still it was progressing, and he thought in the future it would be much more important and prosperous than in the past. He trusted that when the Corporation took over the gas undertaking they would give satisfaction to the consumers, and that the gas might be even cheaper than it was at the present time. The great thing to do was to cheapen as much as possible those commodities that people could not do without. It seemed to him that gas and electricity would run very well together in Newark. A good deal had been said about Mr. West that day. There was no one who more appreciated Mr. West's work and his great ability as a gas engineer than he (the Mayor) did; and he hoped the Corporation would retain his services.

Mr. E. F. Keable submitted "The President"—a charmingly unassuming man who was greatly admired by all of them. During their visit to the works they had seen much which reflected credit both on the Directors and on Mr. West.

The reply of the President brought to a close the first day's proceedings of a wholly successful meeting.

THE BRYAN DONKIN COMPANY.

Equally well arranged and attractive was the programme for the following day, when those members (with a few friends) who had been able to stay in Newark over-night proceeded by motor from Newark Market Place to the works of the Bryan Donkin Company, Ltd., at Chesterfield. With fine weather, the drive through the famous "Dukeries" country of Nottinghamshire, and the return by way of Mansfield, proved most enjoyable. A warm welcome awaited the travellers at Chesterfield, where they were met by their old friend, and genial host, Alderman George Clark, J.P., M.Inst.Mech.E. (Managing Director of the Bryan Donkin Company), and various members of the staff—including Mr. A. G. Webb (Secretary), Mr. Buxton (Works Manager), Mr. Seaman (Chief Draughtsman), Mr. Tucker (Assistant Works Manager), Mr. Cyril Donkin and Mr. Fennemore (District Engineers), Mr. Dickinson, and Mr. Hopkinson (British Furnaces Staff).

Under such able guidance a tour was made of the works, the great extent of which proved a revelation to those visitors who had not seen them previously. Alderman Clark himself was at the head of the parties, and from his wealth of knowledge of the business and the works was able to impart much information during the inspection. Alderman Clark went to Chesterfield from the London works of the Company at Bermondsey in 1900, as Works Manager; and under his control as Managing Director during the past nineteen years, the concern has developed steadily, until at the present time the employees number about 700. Alderman Clark is Chairman of the Gas Committee of the Chesterfield Corporation, and was Chairman of the Society of British Gas Industries in 1921-22. He is also a Vice-President of the British Commercial Gas Association, a member of the National Gas Council, and is on the Grand Council of the Federation of British Industries. He was Mayor of Chesterfield in 1922-23.

History.

The history of the firm goes back much more than a century; the business having been founded in 1803 at Bermondsey, by Mr. Bryan Donkin, F.R.S.; and much varied and valuable work was done right at the commencement, though it is unfortunately impossible to enter into this here. It was between the years 1840 and 1850 that the Company began to devote their attention to the gas industry. In 1847 a special type of valve known as the rack-and-pinion valve was designed at the suggestion of the Chartered Gas Company, of London; and it is still one of the chief products at the Chesterfield works, where over 1000 tons are turned out yearly. Other designs of valves followed for use in different parts of gas-works.

The firm also took up the manufacture of gas exhausters, which has since become such an important section of their business—making what was known as "the 1847 patent." This was afterwards superseded by the manufacture of John Beale's design, patented in 1866. A number of these were made, chiefly in large sizes, and many are running well to this day. They were, however, gradually superseded by a later patent of Beale's, dated 1877, which has many advantages over his earlier efforts, and has come into use more than any other type in Great Britain. A further patent on this design was taken out by Mr. Thomas Donkin's eldest son, Mr. E. Bryan Donkin, who evinced a special interest in this class of machine, and read an excellent paper on the subject at the Belfast meeting of the Incorporated Gas Institute in 1893. He also invented and patented several other improvements in the gas-works apparatus that the firm manufactured, and turned his attention chiefly to developing the business in that direction. He became a partner on the retirement of his father from the business, and was in active control of it for over twenty years.

After a century of eventful history in Bermondsey, the growing interests of the business and the difficulties of transit and expansion on an adequate scale in Bermondsey caused the firm to seek greater conveniences, and the whole concern was removed to Chesterfield. An amalgamation was effected with the firm of Clench & Co., and their well-equipped and modern works taken over and adapted to the combined requirements. The site comprises 14 acres. It is connected by sidings with the London, Midland, & Scottish and the London & North-Eastern Railway Companies, and is in the centre of the great coal and iron district of Derbyshire. Extensions have been continuous, and during the period 1902-25 practically all the departments have been considerably enlarged, until at present the area occupied by the buildings alone is over 4 acres, and the works are equipped with every class of modern machinery. In 1912 the present fine offices were built, the old offices being converted into the general stores. In 1917 a new erecting and testing shop of 7900 sq.ft. area was built, and later a women's canteen of 1440 sq.ft. area. A new fettling shop and sand blast house, a core shop, and works' repair shop have recently been built; and a large ferro-concrete pattern stores in two floors, with a total area of 16,000 sq.ft., is nearing completion. An extension of the valve shop of three bays, each 25 ft. wide by 96 ft. long, has just been started, and further extensions are in contemplation to meet the increasing demand for the Company's specialities.

A "History of Bryan Donkin & Co. (1803-1925)," which is of engrossing interest, has been compiled by Mr. Harry J. Donkin.

Gas Apparatus Manufacture.

The Company have continued at Chesterfield to manufacture their well-known specialities—the positive gas exhauster (which is now made with two, three, or four blades, according to the

EASTERN COUNTIES ASSOCIATION, HALF-YEARLY MEETING.

preference of the gas engineer), gas valves, motor parts, tar and liquor pumps, &c. During this period the usual initiative of the firm in adapting themselves to the changing times has been shown in many ways—notably in the acquirement, from Prof. Rateau, of Paris, of rights in the turbo-exhauster. No less than 183 of these machines are already at work (or on order) in gas works and collieries, and for coke oven installations, doing duty as exhausters, boosters, blowers, &c., representing a capacity of 85,094,166 c.ft. per hour. They can be driven by steam turbine, electric motor, or belt. In addition to high-pressure gas transmission plant, the Company make, under license from the Reynolds Company and the Mueller Company, reducing governors and fittings for district and service purposes. To take the place of the German coke-oven valve, the Company are manufacturing a light pattern valve with internal or external screw, many thousands of which have been sold. A gland plug cock also has been designed, and has met with a large and increasing demand; and the Company are now making a special tar cock for use on tar towers and tanks. In 1921 the firm became interested in British Furnaces, Ltd., who handle every type of heating or fuel treatment equipment as well as small water gas plants and gas-fired boilers. As a matter of fact, some of the furnaces to which Mr. C. Bryan Donkin had referred in his paper on the previous day were seen in operation.

In the huge machine shop, and other parts, a great deal of work of a varied kind for different gas and similar undertakings was noted in progress. To mention some, there was apparatus for the Gas Light and Coke Company, the Birmingham Corporation, the Coppée Company, the Glasgow Corporation, the South Metropolitan Gas Company, the Synthetic Ammonia Company (Billingham), the Aldershot Gas, Water, and District Lighting Company, the Wigan Corporation, the Oxford Gas Company, the Preston Gas Company, the Ripon Corporation, the Liverpool Gas Company, and the Yeovil Corporation, as well as Cambuslang, New Hunstanton, Kenilworth, and Bellshill, and also a number of governors for Copenhagen.

As to the gas type-metal melting installations of British Furnaces, Ltd., it can only be said that the extent to which these have been, and are being, adopted in newspaper and other printing works is remarkable. The particulars of these installations reveal extensive recognition on the part of printers of the advantages of gas in this connection, and a big field of business for the gas industry.

Of all the interesting processes inspected in the works, space will not permit details to be given here. Mould ramming is performed by compressed air machinery of an ingenious character. Bumping machines, sunk in the ground, and also operated by compressed air, attacking the mould from beneath, save a lot of laborious work. Indeed, a principle of the works is labour saving in every possible direction. The core shop has been "manned" entirely by girls for the past twenty and more years. The firm were among the first in England to employ girls for this purpose in an engineering works. It is pleasant work which is excellently suited to female labour. Much attention was devoted to the already mentioned ferro-concrete pattern stores now in course of construction. These were designed, and are being built, by the Company's staff. There is still space on the site for extensions, for which the various buildings have been designed.

Hospitality.

At the conclusion of the inspection, the visitors were the guests of the Company at luncheon in the Station Hotel—with Alderman Clark in the chair. There were also present the Mayor of Chesterfield (Mr. W. E. Wakerley, J.P.), Sir Ernest Shentall, J.P. (a member of the Town Council), Alderman H. Edmunds, J.P., and Mr. Harold Davies (the Gas Engineer). The toast list was of the shortest—"The King," "The Eastern Counties Gas Managers' Association," and "The Mayor and Corporation of Chesterfield."

Submitting the second, Alderman Clark welcomed the Association to Chesterfield, and made reference to his firm's association with no less a person than Murdoch himself. To every gas engineer the name of Murdoch was like a talisman; for he was the father and founder of an industry which, though it had small beginnings, had since grown to such enormous dimensions. Bryan Donkin, the founder of the firm, was born in 1768, at a wonderful period in English history, and was associated with all those giants of science who, without the aid of textbooks, and really of their own knowledge, built the industrial England which existed to-day. In addition to knowing Murdoch, he was connected in business with Telford, Rennie, Bramah, Boulton and Watt, Simpson, Maudslay, Congreve, the two Brunels, and Nasmyth. An entry in Bryan Donkin's diary (under date of January, 1814) had reference to a visit to Boulton and Watt's works at Soho, Birmingham, and was in the following terms:

> "Mr. Murdoch showed me the foundry, which is large enough to melt 30 cwt. of iron at one time. Young Mr. Watt asked me to call on his father (James Watt). Mr. Murdoch accompanied me, and I was kindly received by the old gentleman, who is now 84."

His (the speaker's) firm were proud of their history; not only were they linked with the past, but they were alive to the needs of the present.

The President's reply afforded him an opportunity of gracefully thanking Alderman Clark and the Bryan Donkin Company for all the kindness that the Association had received at their hands.

"The Mayor and Corporation of Chesterfield" was proposed by Mr. F. Prentice and replied to by the Mayor, who stated that the Chesterfield gas and water undertaking was in private hands up to 1895, but was acquired by the town in that year. The purchase money was just under £250,000, and was found by the issue of 2¾ p.ct. stock at a premium of 30s.

Chrisman Down-Run Process.

The down-run process developed under the direction of Mr. C. S. Chrisman, of the U.G.I. Contracting Company, and applied to a carburetted water gas set, has been described, in a paper presented to the Pennsylvania Gas Association, by Mr. L. W. Seltzer, the Engineer to the Reading (Pa.) Consumers' Gas Company. The process is one by which all the gas made on the down run is taken from the bottom of the generator, and led to some point beyond the superheater but ahead of the wash box, thus making the down-run gases by-pass the carburettor and superheater. The idea is based on the fact that the gases made on the down run leave the generator at a very much lower temperature than either the blast or the up-run gases, and that this temperature is far below that required in the carburettor and superheater for efficient oil results. These comparatively cool gases by-passing the carburettor and superheater prevent the unnecessary abstraction of heat from the plant, and the correct temperature for efficient oil fixing can be maintained with a decreased fuel consumption. For the purpose of properly carburetting the gas, it becomes necessary, with this process, to use oil during the up run only. The Gas Company at Reading have used this method of gas making, with a decrease of from 2 to 3 lbs. per 1000 c.ft. in generator fuel, and a considerable increase in the capacity of the set.

GAS FOR INDUSTRY.

By C. Bryan Donkin.

[A Paper before the Eastern Counties Gas Managers' Association, April 22.]

The use of town gas for industrial heating purposes is a subject of interest to every gas manager, as it is adapted to every purpose where heat is required. Even the smallest town nowadays boasts at least one garage where gas can be used for brazing, hardening tools, and other purposes; while its uses in the larger towns and cities are innumerable. I believe that the British Commercial Gas Association have a list of about 3000 distinct trades in which gas is employed. I propose dealing with this subject as far as possible from the gas managers' point of view, bringing forward those arguments for its use in preference to other fuels, which should appeal to the prospective consumer.

The movement now in existence for promoting means of eliminating the contamination of the atmosphere by smoke is a great point in favour of the use of gas, especially in our cities where fog is prevalent; but an even greater advantage is the improved conditions of the workers in those factories employing gas fuel, resulting in better work and greater output. In order to appreciate this, it is only necessary to visit, for instance, a foundry or printing works using gas, and to note the clean surroundings, free from smoke and dust, and the normal temperature of the shops.

The economy of gas does not lie in fuel cost alone. Gas is delivered to the point where it is to be consumed; coal or coke has to be carted, and the ashes have to be removed. No space is required for storage—an important matter in many works where ground space is limited. Labour costs are saved, as no stoking is required. There is no waste of fuel, for gas can be shut off as soon as it is not required. Temperature can be controlled exactly, and heat applied where it is wanted. Labour is saved in cleaning the workshops, as there is no smoke or dust. All these facts should be taken into account when comparing fuel costs. In addition, it is often possible to increase output of a furnace by converting it to gas; fewer furnaces then being required for a given output.

During the war, when furnaces were required quickly and in large numbers, there was no time to go into questions of design and efficiency. Consequently consumers got the impression that gas was an expensive and inefficient fuel. However, very great advances have been made in the scientific design of the gas furnace; and gas can now show efficiencies far greater than other fuels. In order to employ it economically for heating purposes, there are three important points to bear in mind. The first is that the gas and air must be thoroughly and intimately mixed in the correct proportions, and this mixture must be kept constant under all conditions. The second is that this gas-air mixture should be completely burned under conditions producing the greatest amount of heat, and this heat applied in the most efficient manner. The third is that the furnace itself should be properly insulated, for every unit of heat radiating to the surrounding air is so much loss.

Taking the above points in order, it is necessary that either the gas or the air should be under pressure. If high-pressure gas is used, it may be compressed up to 5 to 10 lbs.; if the air is compressed, about 1 lb. is sufficient. There are various methods of mixing the gas and air; one of the simplest being by means of an inspirator (fig. 1). This is essentially a throat

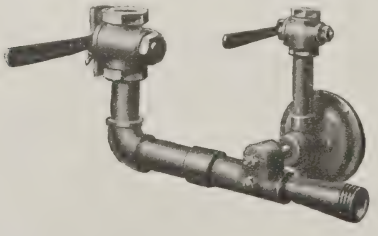

Fig. 1.

of venturi form through which the air from the blower passes, inspirating the gas, which is kept at a constant pressure by a governor. With these inspirators the gas and air are thoroughly mixed, and the proportions are kept constant within 1 p.ct. over large ranges of volume. Thus only one valve is required to regulate the temperature, and the most economical combustion of the gas is ensured. For gas under pressure, a somewhat similar inspirator is used (fig. 2). In this case the governor is not required, as the gas inspirates the air.

Having got the proper air-gas mixture, the next question is how to burn it efficiently and completely so as to produce the

Fig. 2.

maximum amount of heat. Of many methods, one of the most interesting is the so-called surface-combustion system. Fig. 3 shows a furnace in which there are two burners set at an angle, and from them issues the air-gas mixture at such a speed that it cannot light back. This mixture is forced into beds of broken refractory material, where it loses its velocity and burns on the surface, raising the beds to a high temperature without any visible flame, the heat being reflected on to the work from the furnace walls and arch. A perfectly even temperature is obtained over the whole of the interior of the furnace, and it is possible to carry-out the most delicate work without the use of a muffle.

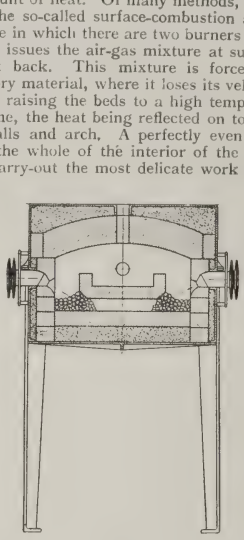

Fig. 3.

The question of insulation has not had the attention it deserves—partly, perhaps, on account of cost; but it is true economy in the end. The refractory lining of the furnace is not usually a good insulator, and it is necessary to back it up with some material having low heat-conducting capacity. Increasing the thickness of the firebrick walls is not of much use; and it is the special insulation that increases the first cost. The applications of heat in industry are so numerous that I can only describe a few of the most common.

The type of furnace just described may be used for tool hardening, annealing, billet heating, refractory testing, pottery baking, &c.

Galvanizing is an important industry, and gas is especially suitable for heating the baths. Fig. 4 shows how the bed of refractory material is arranged along the sides of the bath; the

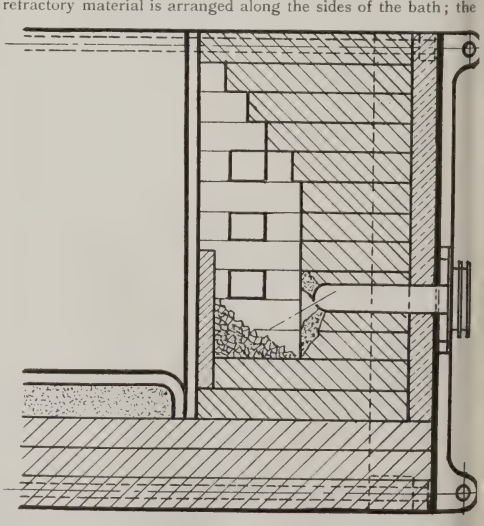

Fig. 4.

ower part being protected by an insulating wall, so that it is ot heated below the normal dross level. This results in per- ectly even heating with no "hot spots," a great reduction in ie amount of dross, and increased life of the bath. It is diffi- ult to give gas consumptions, as conditions vary so much; but ie following figures taken from a bath in actual use may be f interest:

Size of bath, 6 ft. 6 in. by 5 ft. 6 in. by 3 ft. 6 in.
Throughput, 30 cwt. of sheets per hour.
Gas consumption, 3200 c.ft. of 425 B.Th.U. gas per hour.

To keep the bath molten during stand-by periods, 500 c.ft. f gas per hour is required. When a galvanizing bath is con- erted from coke firing to gas, it is usually possible greatly to

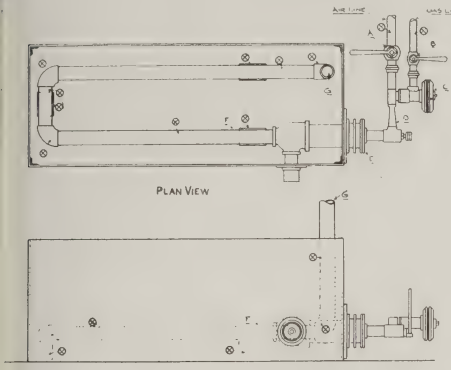

Fig. 5.

ncrease the output; or, conversely, if a gas-fired bath is in- talled, a very much smaller one will do the work.

The use of gas in newspaper printing works is rapidly in- reasing, as the proprietors are beginning to realize its advan- ages; there being no smoke or dust to interfere with the elicate printing machinery. The type-metal pot is heated by urners supplied by the gas-proportioning system; and the out- ut from this type of furnace is very much greater than if olid fuel were used. During stand-by periods the metal is ept molten by an atmospheric burner; the pot thus being al- ways ready for work. For type-metal melting it is always dvisable to have a pot suitable for the normal output, as the as consumption does not increase so rapidly as the output of netal. Therefore a large pot working at a small output is elatively inefficient. Given a furnace of this type working omewhere round its normal output, it is possible to melt over lbs. of metal per c.ft. of gas. This system is, of course, par- icularly suitable for autoplate machines. Gas is also especi- lly suitable for aluminium casting, on account of the freedom rom oxidation; and it is now used exclusively by some of the argest aluminium foundries in this country.

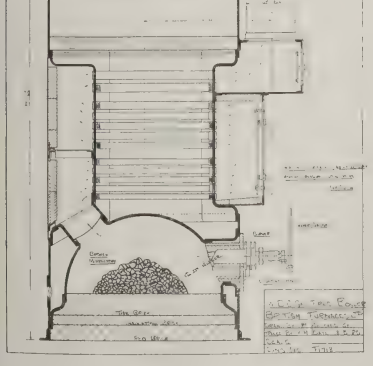

Fig. 6.

In many industries tanks of liquid are required to be kept heated; and the immersion burner (fig. 5) is particularly suitable. The illustration is of a 300-gallon tank, 78 in. by 30 in. by 30 in., with a 4-in. coil.

The burner is arranged in a pipe which enters the tank through one end and is carried round three sides and vertically up. The gas-air mixture being burned inside this pipe, the contents of the tanks are heated without loss by radiation, except from the liquid itself. There is no exposed flame, and the system is very suitable for chemical works, breweries, &c., and with special chemical mixtures for cleaning motor parts in car factories, or cooker parts in gas-works. This should be of special interest to gas managers.

Some processes require small quantities of steam; and the gas-fired boiler supplies a distinct need, as no stoking is required and there is no coal or ash to be carted. For many manufacturing processes it will be found that gas, bearing in mind the collateral advantages, can compete economically with other fuel for steam raising. These boilers can safely be controlled automatically; the steam pressure regulating the burner, and the water level the feed pump. No attendance therefore is required.

Fig. 6 is a section of this boiler showing the refractory bed; the burner being fitted to the fire-hole door. Tests show that an evaporation of 30 lbs. and over is obtained per sq. ft. of heating surface in the combustion chamber.

The following is the result of two tests carried out on two different boilers:

Number of test	1	2
Date	July 21, 1924	Oct. 25, 1924
Heating surface, about	150 sq. ft.	50 sq.ft.
Gas at 60° Fahr. and 30 in. used per hour	3378·32 c.ft.	1078·62 c.ft.
Calorific value of gas (net)	419 B.Th.U.	446·5 B.Th.U.
Amount of water evaporated per hour	1062 lbs.	366 lbs.
Temperature of feed	60° Fahr.	55° Fahr.
Steam pressure per sq. in.	103 lbs.	69·33 lbs.
Barometric pressure, per sq. in.	14·56 lbs.	14·85 lbs.
Heat utilized per hour	1,232,345 B.Th.U.	425,450 B.Th.U.
Heat available per hour	1,415,516 B.Th.U	481,604 B.Th.U.
Net efficiency of boiler	87·07 p.ct.	88·34 p.ct
Temperature of products leaving boiler	403° Fahr.	398·3° Fahr.
CO_2 content of products	11·3 p.ct.	—
Amount of water evaporated from and at 212° Fahr. per sq. ft. of heating surface	8·46 lbs.	8·75 lbs.

Rivet heating is another application for gas, and has the great advantage that the rivets can be uniformly heated without the formation of scale, for, with the proportioning inspirators described, the atmosphere of the furnaces can be set exactly. This question of scale is very important, for, if there is no scale on the rivets, caulking is avoided, thus saving time and labour. The rivet heater is fitted with two burners at the top which are supplied with the correct gas-air mixture by an inspirator. The rivets are fed into a hopper at the back which also acts as a pre-heating chamber, thus utilizing the waste heat. In those works where there is a high-pressure gas pipe- line, the heater can be used as a portable unit with a flexible gas pipe connection.

For the process of steel hardening there are two methods, heating in an open furnace and quenching in water or oil, and the pot hardening system. The furnace shown in fig. 3 is very suitable for the first mentioned, as the atmosphere can be set so that no scale is formed. In the United States the pot hardening system has now come into general use; and it is beginning to attract attention in this country. The furnace in this case is circular; the burners being set tangentially at the top, so that the hot gas swirls round the outside of the pot, heating it evenly. As with this system there is no flame contact, the pots have a long life. Barium chloride and other special hardening mediums are used; and it is claimed that the results are more even and uniform than those obtained in an open furnace or muffle.

Further examples of gas heating for industry are: Forge fur- naces, rod heating, shipyard furnaces, plate heating, case har- dening, annealing, tinning, cone fusion for testing, and brazing torches, &c.

This question of industrial gas heating is one which deserves the closest possible attention by gas managers. Every oppor- tunity should be taken of replacing other fuels by gas, as it means not only increasing the output of gas with the consequent possible reduction in price, but greater satisfaction to the con- sumer, better conditions for the work-people, less smoke, and general improvement in the health and surroundings of the whole community.

I will next show a few pictures of various types of furnaces We then come to the question of efficiencies of different types, and a slide shows graphically the thermal efficiency. The lowest is the ordinary type; second, good ordinary—*i.e.*, well designed with good insulation; third, surface combustion. Be-

tween these should be a line for the converted furnace; for a good ordinary furnace with the usual two-valve control can be fitted with the surface combustion system with great advantage, and will give far better results than the usual type, though not quite so good as one specially designed for the system.

As an example from actual tests, a "Hoe" 6000 lb. type metal pot was converted. On the old system the gas consumption was 7000 to 8000 c.ft. per 24 hours; after conversion this was reduced to 4920 c.ft. per 24 hours—a saving of 33 p.ct. (1500 lbs. per hour). An "Autoplate Junior" was also converted, with the result that 8¾ tons of type metal were melted in 4½ hours by 4398 c.ft. of gas, against 7 tons in 5 hours with 4085 c.ft.—*i.e.*, 1 ton in 30 min. with 532 c.ft., against 1 ton in 43 min. by 712 c.ft. with the old system. This was a saving of 13 min. in time and 25 p.ct. in gas consumption.

A small rod-end furnace, fitted with this system in place of the standard two-valve control, was heated from cold to 1000° C. in 8 min. with 87 c.ft. of gas, as against 10 min. with 100 c.ft.—a saving of 2 min. and 13 p.ct. gas consumption. To hold the furnace at 1000° C. on the old system took 284 c.ft. per hour, and on the new system 198 c.ft. per hour—a saving of 30 p.ct.

[The report of the discussion to which the paper gave rise is held over until next week.]

Gas in the Brush Industry.

The brush industry of the United States has, we learn from the "American Gas Journal," enlisted the aid of gas as a fuel, which is playing an increasingly important part in the brush factories of the country. It appears that horsehair, for bristles, reaches the factories in large canvas bags. This must be carefully sterilized, and to that end huge vats of disinfectant are heated almost to the boiling point; and in these the hair—sacks and all—is immersed. Gas burners keep the liquid at a constant temperature, whereas with the coal formerly used many sacks of hair were destroyed by the unexpected boiling of the disinfectant. When the bristles have been cleaned and sorted, they are dipped in pitch to hold them in the wooden brush-backs. Until recently, the pitch was heated with charcoal, and frequently fires of the inflammable material resulted. Gas burners have entirely done away with this risk. The final stage in the manufacture of many brushes is japanning; and in this work gas has brought about notable improvements. The painted brush-backs were formerly baked in a coal-heated oven, with the result that dust was deposited on many of the wet brush-backs, ruining the high finish. The problem of dust has been eliminated by the use of gas; while the time required to dry brushes has been reduced from twelve hours to an hour-and-a-half in a gas-fired cabinet.

Heating by Gas in Los Angeles.

The gas heating of "height-limit" office buildings in the City of Los Angeles is the culmination of fifteen years of constant effort by the Los Angeles Gas and Electric Corporation. This statement is made by the Corporation's Industrial Engineer (Mr. C. M. Robert) in an article published by the "Gas Age-Record," in which he claims that high office buildings are adapted to the use of gaseous fuel for central heating. Fifteen years ago there were probably not more than a dozen gas furnaces on the Corporation's entire system, and these were house-heating installations. This mere handful was, however, the forerunner of a campaign which has resulted in a city that to-day uses gas to the practical exclusion of all other fuels for the heating of its homes. At the beginning of 1910, there were 66,175 meters on the system; and the average consumption of gas per meter for the preceding year was 22,505,438 B.Th.U. On Jan. 1 of this year the total number of meters had risen to 306,318, with an average annual consumption per meter for the preceding year of 44,135,047 B.Th.U. The rapid increase in population furnished a very fertile field for gas house-heating activity. The burner now used is of the Corporation's own invention. It is installed on the outside of the fire-door, and the gas is drawn through a cylinder with the stack velocity; the air for combustion being regulated by a slide.

An American Refractories Institute.—The announcement is made by "Industrial and Engineering Chemistry" of plans for the formation of a bureau to be called the American Refractories Institute, for the purpose of providing a satisfactory means of contact between representatives of all industries using or manufacturing refractories and for the study of the various economic and technical problems arising with respect to heat-resisting materials. A research laboratory will be operated in connection with this Institute. The Organizing Committee are inviting the special attention of users of refractories to the Institute, in accordance with the fundamental idea of making it a service bureau for the consumer as well as for the producer of refractories. Mr. Macdonald C. Booze, Senior Incumbent of the Multiple Industrial Fellowship on Refractories at the Mellon Institute, Pittsburg, has been appointed Secretary of the Organizing Committee.

MIDLAND JUNIOR GAS ASSOCIATION.

The Annual Meeting of the Association was held on Thursday, April 23, at the Birmingham Council House—Mr. Harry Clark, the retiring President, in the chair.

The annual report was approved on the motion of Mr. J. H. Gee, who took the opportunity of pointing to the responsibility of individual members.

The resolution was seconded by Mr. W. E. Cadwallader (Birmingham).

Mr. A. R. Myhill (Hon. Treasurer) presented the statement of accounts.

Mr. J. H. Gee (Central Laboratory, Nechells), the Senior Vice-President, becomes President, and Mr. C. F. Tooby, Folkes Hill Works, the Senior Vice-President.

Messrs. C. F. Deekin (Cradley) and G. E. Currier (Smethwick) were appointed members of the Council.

Mr. H. R. Hems was unanimously re-elected Hon. Secretary, and on behalf of the members the President paid tribute to the efficient way in which Mr. Hems carried out his duties.

Mr. Myhill stated that he was unable to continue as Hon. Treasurer; and Mr. George W. Smith (Nechells) was unanimously appointed to that position.

The meeting confirmed the re-election of Mr. W. P. Timbrell as Hon. Auditor.

Mr. T. H. Poulson (Stafford) warmly congratulated the Association upon their virility and the excellent work they were doing.

A discussion was opened by the President, on the subject of

UNACCOUNTED-FOR GAS.

It is surprising how much this very important question, gas unaccounted-for, is continually kept in the background by the gas industry. The magnitude of the difference between the amount of gas made and gas sold each year is fully realized when we know that the average quantity of gas unaccounted for each year for 100 undertakings is 7 p.ct. If we take 30 of the largest undertakings that make over a thousand million cubic feet of gas per annum, we find the following startling figures: A total of 9,425,123,279 c.ft., or 47,125,616 therms. I wish to make it clear that these figures do not represent a distinct loss, for the simple reason that the difference in the conditions of measurement between gas made and gas sold, and the inevitable leakage from holders, mains, and services (the latter two are now materially affected by the tremendous increase in road transport), must be taken into consideration; and allowances should be made. Whether the subject is too large for the Junior Associations to tackle it is difficult to say, but we have the opportunity to-day of examining this tremendous difference apparent year after year. There are eight ways whereby we can account for the difference between gas made and gas sold; but I propose to deal with only one, which during my experience in four large centres, I have found to be one of the worst—that is, meters. I will give some practical reasons why meters are guilty. Careful tests have revealed the fact that a very large number of meters register from 3 to 15 p.ct. slow; and in the case of prepayment meters it is a common occurrence for consumers to refrain from inserting another coin because they can obtain sufficient light for a period before the valve shuts-off the gas properly. This has been most marked since we have had war and post-war gas. A fair basis shows that out of 1000 meters, 250 register, on an average, 15 p.ct. slow—an alarming figure, but true. I will now deal briefly with the question of the cost of inspection, changing, and repairing prepayment meters, the gas through which forms the backbone of our consumption. Experience has proved that the most effective and economical way of tackling these meters is for the defect to be found by test meter inspectors on the district—not by ordinary meter inspectors. The former examine thoroughly 25 to 30 meters per day; and we are sure that only faulty meters will be changed and repaired. The total present-day cost is £1 5s. 6d. per 3 or 5 light meter. Many will disagree with this expenditure; but to those I say: We have no guarantee that the meters will remain at 15 p.c. slow, and the chances are that the loss will soon increase, whereas, when the meter is changed, you have the guarantee and satisfaction that all is well for some time to come. In the remarkable paper given by Mr. A. T. Gilbert, in November 1922, on "Gas Meters, Their Construction and Application" (see "Journal" for Dec. 6, 1922, p. 622), the author states that there were 78 meters exchanged, and the total gain in gas was 844,000 c.ft.—an average gain per meter of 10,800 c.ft. Assuming that the cost of finding each meter was 2000 c.ft., then the net gain per meter was 8800 c.ft. Far too much importance has been attached to the checking of the consumption figures by the rental department, who could be easily misled by the "fairy tale;" besides, inquiries are a delicate matter. It is much better to send and test on the consumers' premises. For many years I have studied closely the question of unaccounted for gas and its relationship to the registration of all kinds of gas meters. I do not hesitate to recommend strongly the changing of all dry gas meters once in five to eight years, re

nembering that same are subject to much higher pressures and consumptions than was experienced years ago.

Mr. R. G. Marsh (Birmingham Gas Department), who was unable o be present, wrote as follows: One aspect of the manner in which ve arrive at the figure of unaccounted-for gas has always struck me as being rather irrational. I refer to the fact that corrections or temperature and pressure are applied to the registration of the station meters at the works, while no correction whatever is applied o the registration of the meters which re-register it on the district, where the variations in temperature and pressure are at least likely to be just as important in their effects on the actual volume of the gas. As a matter of interest, I have made a few observations during the past week of the temperature of gas as actually delivered to consumers' meters on the district; and the average I have obtained is 40° Fahr. The gas is corrected to 60° Fahr. when passing through the station meters. Allowing a variation in volume of 1 p.ct. for each 4° Fahr. difference in temperature, this means that there is 3½ p.ct. shrinkage in the volume of the gas after it has passed the station meters and before it reaches the consumers' meters. There is, of course, a correction to be applied which acts in the opposite direction in respect of barometric changes. Taking the average figure to be 29½ in. in Birmingham, this represents a difference of about 1½ p.ct. increase in volume, due to lessened atmospheric pressure. The net result is that there is an amount of approximately 2 p.ct. which appears in our unaccounted-for figure, and which really is accounted for by the causes I have mentioned. Apparently, therefore, instead of our figure being about 5 p.ct., it should really be about 3 p.ct. I have not taken gas temperatures during the midsummer quarters; but I should be surprised if any very great difference in temperature would be found from the figures I have before mentioned. Some years ago we made a similar investigation, and the temperatures we obtained then very closely agreed with the figure of 46° Fahr. that I have mentioned. An amount of 2 p.ct. on the total quantity of gas sent out by an undertaking such as ours represents a loss in revenue of a very serious nature; and possibly it may be found worth while, at some later date, for gas undertakings to fit consumers' meters with some type of automatic gear to correct the registration to normal temperature and pressure. There has already been some work done on this question; and I think it is a practical proposition. The objection to it is, of course, that such an appliance would add to the expense and complication of meter mechanism, and it is desirable to keep such apparatus as simple and reliable as possible. On the facts ascertained, however, it would seem that there is an important percentage which is recoverable, and which at present appears against the undertaking, and is put down as unaccounted-for.

Mr. J. Hewett (Birmingham) observed that apart from the question of the registration of the meters in relation to temperature and pressure, there were other factors to be taken into account. There were leakages from the gasholders and other apparatus, as well as in the mains and services; and in Birmingham the unaccounted-for gas worked out at about 80,000 c.ft. an hour. An attempt was made to arrive at the amount of loss in the mains prior to 1914. The work of inquiry took two years, and, in all, they dealt with fifty miles of mains. The Department then had 900 miles of mains. They selected the routes along which were the oldest mains, and closely-spaced indicators were used. The losses at individual leakages were not severe, though in the aggregate the amount lost was large. Another cause accounting for some loss was the blowing and tilting of the holders; while a good deal of gas was lost in the making of connections. In his opinion, however, it was cheaper for the Department to lose the volume that now escaped into the atmosphere than to use a special apparatus by which the gas could be locked in. As to the estimates of non-metered supplies, for public lighting, &c., he could not say whether or not they were near the mark. In his own opinion more gas was used through the lamps than was credited in the books. Another factor was the use of by-passes.

Mr. S. W. Simmons (Dudley) attached great importance to the correcting of temperature and pressure. He complained that the meter readers were too favourably disposed to the consumer. At Dudley they had substantially reduced the leakage. He was satisfied there was a tremendous amount of unaccounted-for gas in public lighting. A close supervision of the by-passes was essential.

Mr. W. L. S. Spinks (Birmingham) mentioned the reference by the President to unaccounted-for gas due to meters registering slow. He thought it was possible to exaggerate this. If a dry meter was defective in registration, and 15 p.ct. slow, the chances were that some of this might be due to a leaky diaphragm. There were many meters which would register correctly at the normal rate at which they were tested; but if gas was passed at the rate of 120 c.ft. an hour, the registration might be 8 p.ct. fast, due to the way in which the valves were set. Temperature differences were responsible for much loss.

Mr. T. H. Poulson (Stafford) thought all gas unaccounted-for rose during the war period. It was so at Stafford; but they were now getting back gradually to pre-war figures. It was a paying proposition to deal promptly with small leakages. As to the reading of meters, they adopted in Stafford a system by which a responsible man went through the meters twice a quarter; he examined the meter book, made current entries, and then compared them with the previous records. If there was any serious deficit, he looked for an explanation. By this means considerable reductions had been made in regard to leakage.

Mr. J. H. Gee (Nechells) accepted Mr. Marsh's figures as to temperature, and pointed out that in an excellent statistical summary on the subject, Dr. Davidson gave the atmospheric temperature as 48° Fahr. for the whole year. [See the "Journal" Diary and Gas Calendar for 1925, p. 150.] This gave an apparent loss of 3 p.ct. on a moist gas.

Mr. Hewett pointed out that the services were so close together that, in making connections, &c., it was practically impossible to interrupt supplies. The unaccounted-for gas in Birmingham averaged 4·6 p.ct. over 25 years; and the loss was, of course, greater in the winter, when the actual consumption was 70 to 80 p.ct. more than in the summer.

SCOTTISH JUNIOR GAS ASSOCIATION.

(WESTERN DISTRICT.)

The Annual General Meeting was held in the Ca'doro Restaurant, Glasgow, on Saturday, April 18—Mr. M'Isaac, President, in the Chair.

The Hon. Secretary submitted the Council's annual report, which recorded that there was an increase of 30 members during the session; the total membership now being 355.

The Council's recommendation was unanimously adopted to send a donation of five guineas to the Gas Exhibit at the British Empire Exhibition, 1925, and five guineas to the Education Scheme of the Institution of Gas Engineers.

For the best paper read during last session, the adjudicators awarded the first prize to Mr. D. M'Kerracher, B.Sc., for his paper on "Heat Transmission," and second prize to Mr. R. Sturroch, Ardrossan, for his paper "A Chemist on Works Practice."

After the donations had been accounted for, the session closed with approximately £50 in hand. The Council's report was unanimously adopted.

Mr. R. Gray, Assistant Manager, Hamilton, automatically becomes President for next session. Mr. James Hall, of Glasgow, was unanimously elected Vice-President. Mr. J. Murray was re-elected for the post of Secretary and Treasurer. The following members were elected to Council after a vote by ballot: Messrs. James Brown, Glasgow; John M'Intyre, Glasgow; John Teape, Glasgow; R. Fife, Kilmarnock; S. M'Gowan, Glasgow, and R. Keillor, Greenock.

A letter was read from Mr. James Lowe, of Auckland, New Zealand, congratulating the Association on having attained its majority, and wishing all prosperity. It will be remembered that Mr. Lowe was the first President of the Scottish Junior Gas Association.

The Chairman then called on Dr. Smith to address the meeting.

CURRENT TOPICS.

By Dr. E. W. Smith, F.I.C., M.I.Chem.E. (Technical Director of the Woodall-Duckham Companies).

On looking back over the last twenty years, one is impressed with the enormous strides that have been made in the "technicalization" of the gas industry. This is not yet complete. The technically-trained man is not yet sufficiently used, and when he is used he is not given sufficient responsibility. This is largely due to the fact that the right type of technical man, having broad views, good personality, and human interests is difficult to get. However, technical men are being employed more and more in connection with the production of gas. More technical men should be employed in connection with the utilization of gas, including its distribution.

I would like to say one word in connection with the duties of those who are responsible for the juniors in the industry. Every encouragement should be given to technical training. The man who is prepared to work in his own time, qualify himself in various ways for the job he holds, and for the jobs he hopes to hold, should be treated differently, from the point of view of salary and advancement, from the man who, while doing his bare duty, has no ambitions, and is little more than a time-server. There is no room in any progressive industry for many time-servers, and the stultifying influence on progressively-minded young men of the "seniority" basis of advancement will have to go.

In speaking of the necessity for technical or scientific training, it is often overlooked that scientific training is not confined to a knowledge of chemistry, physics, and the generally recognized sciences. There is definitely a science of industry, a science of commerce, and a science of business organization and of management. It is not sufficient to work from hand-to-mouth, and deal with the problems that arise, as they arise. An industry, if it is to be anything at all, and progress in the way it should, must have men at the head of its undertakings who plan for the future, who organize before the event, who shape the fate of their industry, rather than allow external influences to shape it and them. Our industry is exactly what we shall make it; and I am sure that, with proper foresight, true conceptions, and scientific business organization, it can hold that position which is second to none in our country—a position of directing the utilization of the whole fuel resources of the country.

At present, for various reasons, the British gas industry is further advanced than the gas industry of any other country; but while believing this, I know that in some details other countries have much they can teach us. I am always very much impressed by the organization of the American Gas Association. I have attended a number of their meetings, and know to a large extent the inner workings of their organization. One notes that it has been found possible for those engaged on the contracting side of the American gas industry to associate on an equality in that Institution with those engaged on the gas production side, to the considerable advantage of the industry as a whole. One also notes that the membership is based on individuals and individual qualifica-

tions rather than on the positions men hold. One is impressed by the volume of really valuable committee work that is done, the results of which are published by the Association. One notes that there is a committee of the American Gas Association for every distinctive activity of the American gas industry. These committees are alive, productive, and inspiring to the whole industry. They are vitalized by a selection of individual membership of each committee which is appropriate and conducive to activity and the production of valuable reports. Like all committees, they depend for their success on the energy and capacity of their chairmen and secretaries. To a very large extent these posts are held by highly-experienced, technically-trained young men. The chairmanship of any particular committee cannot be held for more than one year; and there is great competition to make each succeeding year better and more productive than the last.

At the annual meetings each section has its own session, and the reports of the committees have to bear the criticisms of the annual meeting. A little more of the American spirit and point of view would not harm the British gas industry, as I am confident that under such a system the results would be at least as good as those acknowledged to have been attained in the American Gas Association

The progressive industrialist is a convinced believer in the advantages of gas over solid fuel or oil, and the greatest deterrent to its much extended use is the cost per therm for industrial purposes. In this connection I believe that the whole question of the methods of charging for gas for different purposes is worthy of reconsideration; and I would like to see a committee of the National Gas Council, consisting of experienced business men, working in co-operation with first-class accountants, devising a scheme which should have for its objective the encouragement of the maximum possible sales of gas in all areas. At present there is not sufficient differentiation between the price charged for gas used in small quantities for lighting, and the price charged for larger quantities, such as domestic heating, motive power, and industrial furnaces. In many districts, restaurants, which are commercial and industrial enterprises, and which use annually a great deal more gas than many of the recognized industrial concerns, are paying for gas at the domestic rate. In many areas gas used in fried fish shops is being charged for at the domestic rate. The man who heats the whole of his house by means of gas alone or gas and coke, using up to 20,000 c.ft. per quarter in the winter months, pays the same price for his gas in all areas as the man who uses gas for lighting alone, amounting to perhaps 3000 or 4000 c.ft. per quarter. This does not appear to me to be commercially sound. It is altogether too much of a tax on the general consumer. The larger user, with his comparatively low installation and maintenance cost to the gas company, is paying for the relatively high installation and maintenance cost of the small consumer. This is very well recognized in the electrical industry. The over-all cost of production of electricity depends on very similar factors to the over-all production cost of gas.

It is not to be expected that among our small and moderate sized gas undertakings there will be facilities for getting at the bearing of all factors on one another in connection with the cost of production and sale of gas; but in the larger companies, and in the National Gas Council, which represents the whole, it should be possible for a thorough study to be undertaken of the whole subject, and a report made on the effect of various factors on the selling price of gas, and recommendations prepared as to the possible methods of differentiating between the charges that are justified against various classes of consumers. As an example of the type of thing I mean, it is worth while considering why it is that some foreign countries are able to dump into England goods at a price which is so much lower than that at which the same goods could be produced in England; the difference not being accountable for by the lower wages paid. One European country may be producing a particular type of article which requires plant and machinery of an expensive type. If this plant and machinery were to be used for 8 hours a day, the cost of production would compare with the cost of production in England, and would be economic in its own country. By working that plant and machinery, the interest on which is a big proportion of the total cost of production, for 24 hours a day, the cost of production of the articles made in the extra 16 hours is reduced to a very low figure; and this is approximately the figure at which they can afford to dump these articles in foreign countries.

Some time ago, a large industrial firm desired to utilize gas to the extent of over 20,000,000 c.ft. a year in its process. They could afford to pay 7d. a therm for the gas. The local gas company in looking through its accounts found that, by selling at 9½d. a therm, they made about ½d. a therm profit; and they came to the conclusion that 9d. a therm was the absolute minimum at which they could afford to sell the gas. During the conference, the question was asked "How much plant have you that is standing idle all the year round, or during any one week?" It was found that there was 25 p.ct. of plant standing idle, on which interest on capital was being paid. The question was also asked "How much is your gas costing you per therm into the holder?" The reply was "2½d." It was then pointed out that, as establishment charges, salaries, the distribution system, and interest and depreciation on unused plant were all having to be borne by the gas that was being sold, and not by the gas they were capable of making, it was possible that it would pay as well to sell the 20,000,000 c.ft. of gas per annum at 3d. per therm, as to sell their then output at 9d. per therm. This threw a new light on the whole subject, and from then on the prospective consumer had no difficulty in getting his 20,000,000 c.ft. guaranteed consumption at 7d. per therm.

Our electrical friends have appreciated the importance of differentiation of rates for some time, and many of the schemes which have been adopted are worthy of very close study on the part of the gas industry. It is well known that some electrical concerns are in effect being subsidized by gas undertakings. It is also well known that some electrical undertakings are subsidized from the local rates. At the same time there are successful electrical undertakings which have adopted systems of charging for electricity such as the Norwich rate and modifications thereof, which to my mind are sound in principle and excellent in results. One electrical concern in a large city in the North of England is successfully competing with gas for practically all purposes, on a cost basis, because of some such scientific system. I am sure that much more could be done than is being done in this particular direction by our own industry. It may or may not require legislation, but the first requirement is for us to study the subject in all its ramifications, and thoroughly understand it, in order that the best schemes may be adopted.

The cost of industrial gas to the consumer is not the only factor that influences him in making his decision as to whether or not to use town gas in his processes. A great deal still needs to be done in connection with the efficiencies obtainable in industrial furnaces, and there is little need to remind you that, if the amount of gas used in a given process can be reduced to half, the consumer is as satisfied as if the price had been reduced to half. In many cases such a reduction is not possible, but there are a large number of furnaces working in industry at the present time which are giving efficiencies in heating, quite apart from particular methods of working the process, which are from 20 to 60 p.ct. better than the general run of furnaces.

The furnace business cannot be run on similar lines to the gas cooker or fire business. The large bulk of the latter is done through the gas companies, everything is standardized and except for minor adjustments for varying quality of gas and pressure, a gas fire and a cooker which give satisfaction in one locality may give equal satisfaction in another. Consequently mass production is possible with such apparatus, and little technical supervision is necessary, either in the specification for room heating or cooking, or in the actual fixing of the appliances. This does not hold in furnace work. Practically every furnace has to be specially constructed for the job it has to do, and every furnace should be started up in the first instance by a highly-specialized furnace expert.

There is excellent furnace equipment on the market made by one or two experienced firms. There is also a great deal of rubbish, just as there is on the lighting burner and fitting side. The gas companies and consumers look too much to the question of first cost, and too little to the question of upkeep and of obtaining all necessary results and conditions of operation.

I do not intend in this paper to go again into the question of what constitutes first-class furnace design and operation. I would, however, like to indicate to you some directions in which industrial gas is extending in its use. Four years ago comparatively little gas was used in the printing trade in England. At present British Furnaces, Ltd., alone have over 100 installations in the London printing trade. The new principle of heating, known as surface combustion, but without the employment of the diaphragm, has been successfully applied to junior and senior autotype machines, to Hoe furnaces to Winkler machines, and to the backing-up furnaces usually employed in the printing trade. In most cases this equipment has displaced coal and coke, with all the consequent advantages of increased output, increase in speed of heating, better conditions in the workshop, freedom from presence of solid fuel, its storage, and any necessity for disposal of ashes. No fewer than 75 printing shops are using this equipment in London. In some cases it has displaced already existing gas apparatus, and the results have been so remarkable that, when they became known, other printing establishments rapidly converted their furnaces from coal, coke, or oil, to gas.

The autotype machines vary in size. They may contain from 13 tons of metal down to 7½ tons. The rapidity of heating with the equipment in question will be appreciated from the fact that 7½ tons of stereo metal are brought from cold to a liquid state, at a temperature of 600° Fahr., in under 1½ hours; and during the period when plates are being cast, the casting and melting takes place at the rate of 420 lbs. of metal per minute. During the ordinary working week these baths of metal are kept liquid during the day, while the furnaces are not in operation, and the gas used for maintaining fluidity and for melting the metal during process work corresponds to 1 c.ft. (500 B.Th.U. gross) for every 10 lbs. of metal melted. During the working period, and excluding the gas used during

ne stand-by period, the quantity of metal melted per c.ft. is s high as 26 lbs. By substituting this equipment throughout neir furnaces, one large printing organization state that they re saving over £2000 a year on gas consumption alone, equal) 24,000 c.ft. of gas per week on each of 9 furnaces. But nis is not the only saving. It was common in the printing rade for the cast-iron pots to fracture, due to irregular and ocal heating. These pots are valued at between £50 and £60 ach, and one firm alone, over a lengthy period, lost one pot er fortnight, which was shown in their books as being a net oss of £1248 per year. British Furnaces have had their quipment in use now for over three years, and there has not een a single instance of a fractured pot. In order to gain onfidence, it is necessary that the furnace builder shall be repared to give guarantees. If he does not fulfil them, he hould remove his equipment, and the consumer should be elieved of the cost thereof.

It would be a good thing if industrial concerns in the gas ndustry were to give a lead in connection with the utilization f town gas for industrial purposes. I am glad to state that Messrs. Thomas Glover, of Edmonton, have converted all their urnaces to gaseous firing, including crucible tinning and dross urnaces. The provincial newspapers are rapidly following he lead of the London newspapers, and many of them are now n gaseous firing. There is no doubt, particularly on high output work, such as that in the printing trade, gas is by far he best fuel. Another point of interest is that in no single nstance in the printing trade in London has there been any lismantling of gas equipment due to defect in the last three ears; so that the equipment is not only efficient, but it is fool-roof and practical.

Another direction in which gas is being applied with advan-age is in connection with steam raising for hotels and indus-rial concerns where cleanliness and space occupied are of mportance. Without feed water heaters, efficiencies can be guaranteed, for load conditions varying from 50 to 100 p.ct. of the capacity of the boiler, of between 85 and 90 p.ct. The water-level in the boiler can be maintained automatically, and the gas consumption regulated by the pressure of the steam in the boiler. A full description of such equipment was given by Mr. James W. Reber before the Midland Junior Gas Associa-tion on Feb. 27 (see "Journal" for March 4, p. 529).

The Woodall-Duckham Cochran boiler, which has been modified for gaseous firing, has a special advantage over other gas-fired boilers in that it has a definite combustion chamber, and a refractory radiating bed giving all the advantages of a highly-incandescent coke fire. It is possible in a few hours to convert the boiler from gas to coke, or the reverse—a con-venience which is readily appreciated by the consumer.

Another matter on which I should like to touch, which does not come directly under the purview of a junior gas association, but which is of great importance to the gas industry, and about which juniors should be fully informed, if they are to take senior positions, is one which has recently been raised by the tar distillers of Scotland through a paragraph which ap-peared as an advertisement in the "Evening Times" on Friday, March 6. In this paragraph the tar distillers proved to their own satisfaction that it is much more profitable for gas undertakings to sell crude tar to the distiller than to attempt to supply the requirements of the local surveyors for road tar. The paragraph is a piece of the best special pleading that I have read for some time; but no one should complain about it. It is perhaps worth while, however, putting forward another point of view. Mr. Napier, of Alloa, has stated that gas undertakings can make in some cases 40 p.ct. more profit out of their tar by distilling it themselves for road purposes, than if they sell it as crude tar to the tar distiller; and Mr. Napier has backed up his opinion by installing a plant in which to prepare his road tar.

There is no doubt that many road surveyors have found difficulty in using the reputedly prepared tar with which they have been supplied. The fault itself does not lie wholly at the door of gas undertakings. Much crude tar has been sold by the latter to road surveyors through intermediate channels, and it has reached the surveyors after little or no treatment, and the gas undertakings have received most of the blame. It goes without saying that dehydrated tar, pure and simple, is not suitable for road purposes in most cases, and many dehydrating plants are not capable of producing road tar. It is also incon-trovertible that many undertakings have dehydrating plants which are capable of making, and do make, road tar equal to the best that is being produced by any tar distiller. I am speaking with full knowledge and experience of this particular matter. In by far the majority of such cases the profits ob-tained for the tar produced by the gas undertaking are far in excess of the figure that the distiller can afford to pay for the crude tar. It is obvious that this must be so. The cost of conveyance of crude tar to the distillers' works, and of the pre-pared tar from the distillers' works to the road surveyor, in practically all cases, is considerably greater than the cost of carriage of prepared tar from the works of the gas undertaking to the local surveyor; and the crude oils obtained during dis-tillation are still available for sale to the distiller. The road tar market is a seasonal trade, and the multiplicity of gas undertakings have in total not only better storage facilities than the small number of distillers, but these facilities are geographically very much better dispersed and placed for the convenience of the road surveyor.

The advertisement in question stated that "Dehydration, by the very nature of the process, is incapable of producing a properly distilled tar of uniform quality suitable for roads." This is perfectly correct, but no gas engineer sells dehydrated tar as such, if he is asked to supply tar which shall conform to the Road Board Specification; and he is just as capable as the tar distiller of producing, where suitable plant has been installed, tar of a satisfactory and uniform quality, particu-larly in view of the fact that he is dealing solely with his own crude tar, and not with varying qualities and quantities of different tars from different works.

As regards the production of special road preparations such as bitumen mixtures and "filled" tars, these have been made for some time by the Glasgow Corporation Gas Department, and bring at least as high a price as reputedly similar prepara-tions made by the Scotch tar distillers. Many of the smaller undertakings—such as Dunfermline, Alloa, and Dundee—are following the lead given by the Glasgow Corporation.

The advertisement in question pleads that the "bulk of the crude tar produced is at present sold by gas undertakings on a sliding-scale, rising and falling with the values of pitch, oil, and naphtha month by month, and these values must always be the basis governing the price of tar." This is not quite correct, because values of pitch, oil, and naphtha have not necessarily any relationship to the value of prepared tar for road purposes; and the prices obtained for prepared tar have, in the past, been such as to show a considerable margin over those received from the tar distiller for crude tar. This can be readily realized when it is appreciated that the cost of con-version of crude tar to prepared tar for road purposes, and to meet the Road Board Specification, unless the crude tar is very high in water, is practically covered by the value of crude benzole, &c., obtained during this treatment. If gas under-takings thoroughly study the requirements of the Road Board, they are capable of enhancing the value of their tar, and are also in the happy position of being able to vary slightly, at the request of the road surveyor, the quality of their product.

There has been a great outcry during recent years concern-ing the necessity for smoke abatement. With this outcry the whole gas industry is in agreement. The one contribution that the industry has made up to date—and it is a very big one—is to advocate the use of gas wherever possible; but it must be remembered that in the production of town gas it is necessary to produce coke, and coke is the greatest asset that gas undertakings have. It is nevertheless looked on as being a worry and a nuisance in many cases. In the past coke has either been shipped abroad or used largely in industrial pro-cesses.

The smoke nuisance is largely caused by the 38,000,000 to 40,000,000 tons of coal which are used throughout Great Britain in the domestic fire; and until this tonnage is materially reduced, there is no hope of abating the smoke nuisance. Now, the gas industry has for sale approximately 8,000,000 tons of coke annually. There are periods in the year when many concerns accumulate large stocks of coke. There are other periods when stocks are depleted. The prices ob-tained vary almost universally with the stocks held. The sale of coke is also widely influenced by the condition of trade.

You will agree with me when I state that, if coke could be used in place of coal in the domestic grate, not only should we obtain a comparatively smokeless fire, but the demand for coke would vary with the demand for gas, and therefore corre-spond with its production. There will also continue to be a demand for coke for industry; and assuming that in the very near future 10 p.ct. of those using coal in the domestic grate were to be converted to the use of coke, the whole of the available gas-works coke would be absorbed at an average price greater than that obtained at the present time. What is to prevent such a state of things coming to pass?

The principal objections to the use of coke as a substitute for coal are:

1. Its high moisture content.
2. Its poor grading and screening.

From a large amount of experimental work I have person-ally carried out, I am confident that, if coke of a regular and uniform size of $\frac{3}{4}$ in. up to $1\frac{1}{4}$ in., large coke being broken when necessary, and with a moisture content no higher than 5 p.ct., were put on the market, acceptable fires would be obtained in by far the majority of standard grates. The gas industry would then not only supply gas for most purposes, but would also supply coke, and would have gone a long way towards the ideal of its becoming the sole providers of domestic and industrial fuel.

Discussion.

Mr. James Graham (Kilmarnock), thanking Dr. Smith for his address, commented on the fact that gas engineers' activities were hampered by the various committees which at times were not as interested as they might be in the general welfare of the industry. He suggested that the hire-purchase system might be advantageously used to induce consumers to fit industrial appliances.

Mr. R. Gray (Hamilton) asked Dr. Smith if he could say that a large-unit gas-fired boiler capable of heating a hall for about 2000

people was economical, and if the present quality of dehydrated tar sent out from gas-works could compare with others on the market for road purposes.

Mr. Simpson (Greenock) asked Dr. Smith if he had found coke suitable for domestic fireplaces.

Dr. Smith, with regard to Mr. Gray's question about the boiler system, said that, if the cost were taken on purely a fuel basis, then it was not economical to instal a gas-fired boiler, but attention must be given to labour values, available space, &c.; and when these were all taken into account, there was no doubt about it that gas was the cheaper way of heating large places. With regard to coke for domestic fires, Dr. Smith instanced the recent exhibition at Manchester, where a coke fire was used continuously for 14 days, and the cost worked out at about ½d. per hour.

On the motion of Mr. M'Isaac, a hearty vote of thanks was accorded to Dr. Smith for his address.

YORKSHIRE JUNIOR GAS ASSOCIATION.

A meeting of the Association was held on Saturday, April 18, over sixty members (under the presidency of Mr. E. Gillett, Bradford) assembling at the engineering works of Messrs. J. Blakeborough & Sons, Ltd., of Brighouse. Among the visitors was Mr. W. B. M'Lusky, the Engineer and Manager of the Halifax Gas Department, who is the representative of the Manchester District Institution of Gas Engineers on the Council of the Yorkshire Junior Association.

On behalf of the Directors of the firm, Mr. C. J. Vickers welcomed the visitors, who then made a tour of the works under the direction of Mr. Vickers and Messrs. H. Tart, H. Stott, and A. Hopkinson.

Messrs. J. Blakeborough & Sons, Ltd.

In 1886 the firm was launched under the title of J. Blakeborough & Sons. Situated in the centre of Brighouse, the premises were known as the Commercial Iron and Brass Works up till 1890, when Messrs. Blakeborough finally vacated them. As the business grew, the old site became crowded up, and in 1875 it was decided that new premises must be built where expansion would be unrestricted. Land beside the main line of what is now the London, Midland, and Scottish Railway Company, at Woodhouse, was purchased, and an iron foundry was erected and equipped. In 1892, mechanics' shops and pattern-making shops were built alongside the iron foundry, and since then extensions have been practically continuous up till a recent date. During the war large additions to the premises were made to meet the demands of the British Admiralty; the adjoining site formerly occupied by the Rastrick Gas Company's works being incorporated, together with the intervening street. Later, the firm became associated with Messrs. George Kent, Ltd.

Woodhouse Works.

Started as an iron foundry to relieve the pressure on the Commercial Iron and Brass Works, Woodhouse Works now occupy an area of about 13 acres. The site was well chosen; it adjoins, on one side, the main line of the London, Midland and Scottish Railway Company, and on the other the canal that runs from the Humber to the Mersey, connecting Hull and Manchester. A siding from the railway penetrates to the heart of the works, affording facilities for the transport of raw materials and finished products, and forming, in fact, a private railway system operated by the firm's own steam locomotive.

In addition, a tramway system is laid throughout the whole works, serving for the transport from department to department of parts in course of manufacture. Woodhouse Works is a compactly organized establishment. Offices, power-house, pattern-making department and stores, foundries, machine shops, brass department—comprising foundry and machine shops—testing department, laboratory, erecting and dispatch departments, are all grouped in due order, constituting a complete unity.

After the inspection, the visitors were entertained to tea in the workmen's large canteen.

Mr. Gillett said he was surprised at the magnitude of the firm. The shops, and the well-organized system of production, were certainly worth seeing; and he felt sure that every member had benefited considerably by the visit.

Mr. J. B. Balmforth (Bingley), proposing a vote of thanks to the firm, said that Messrs. Blakeborough's was a name well known throughout the whole engineering profession.

Mr. T. Clarke (Brighouse) seconded the proposition, and paid a fine tribute to Messrs. Blakeborough's for the quick and efficient service they rendered to gas-works generally. Regarding the merits of their valves, he had always found them to be effective and reliable.

Mr. Vickers, responding on behalf of the firm, said that if the members had enjoyed the visit, the firm were amply repaid.

Midland Association of Gas Engineers and Managers.—The spring general meeting of the Association will be held at Oxford, on the invitation of the President, Mr. W. E. Caton, and the Chairman and Directors of the Oxford Gaslight and Coke Company, on Thursday, May 7.

PROGRESS OF APPLIED CHEMISTRY.*

A Few Extracts.

The Annual Reports of the Progress of Applied Chemistry, issued by the Society of Chemical Industry, are authoritative reviews packed with useful information on which complete reliance can be placed. In Vol. IX., which has just been issued, the section on Fuel is contributed by Prof. J. W. Cobb and Mr. H. J. Hodsman, of the University of Leeds, and that on Gas, Destructive Distillation, and Tar Products by Dr. W. B. Davidson. Each constitutes a concise account, together with critical comment, of all the more important developments which took place in 1924 in these particular branches; and all who wish to be well informed on these matters will find the reviews of the utmost value.

Power Production.

It is, of course, neither desirable nor necessary to recapitulate what is set down in these two sections; but attention may be drawn to one or two points. It is only a matter of a few weeks since a descriptive article of the Brunler submerged-flame boiler appeared in the columns of the "Journal" (March 11, p. 508). Such a method of power production, state the authors of the section on Fuel, would demand a fuel freed from sulphur to a superlative degree; and even then it could not be assumed that trouble from the acid oxidation products of nitrogen and from hydrogen peroxide would be non-existent. In dealing with power production, they mention the mercury-vapour turbine due to W. J. Kearton. This works between temperatures in a range above the boiling-point of mercury; the vapour expanding into a condenser functioning as a steam boiler, the steam output of which drives a turbine of the normal type. "While novel and revolutionary methods of improving the efficiency of methods of utilizing fuel by means of steam engines naturally excite great interest," state the authors, "it remains true that the economy most easily effected is the operation of ordinary plant to the best advantage. It is notorious that, if the general standard of steam production were merely brought up to what is good boiler-house practice, great savings in fuel would result."

Carbonization.

The heat change which accompanies the carbonization of coal has been the subject of a number of researches both on the laboratory and the industrial scale. Some years ago H. Hollings and J. W. Cobb, by applying a differential method, divided the carbonization process into stages in which heat change was either exothermic or endothermic. In this research a quantitative estimate of the heat involved in the different stages was not attempted, but it was concluded that the total heat of the reactions was small. The subject has been recently examined again with considerable refinement at the U.S.A. Bureau of Mines Station, Pittsburg, by J. O. Davis and P. B. Place, who measured the heat change at different temperatures calorimetrically. The results showed that the reaction heat was in any case small compared with the total heat effects in the process, and in practice negligible. At low and high temperatures of carbonization the process was endothermic; at intermediate temperatures (500° C.) exothermic.

On the subject of low-temperature carbonization, mention is made of the extensive examination, made by K. B. Edwards, of a blast-furnace tar, Coalite tar, and tar from a Maclaurin plant and from continuous vertical retorts. All were found to be essentially of the same character, yielding, except for the higher phenols of the fuel-oil fraction, products of a low value. Phenol itself and other products of known technical value were absent.

Very interesting are the remarks on coke and its combustibility. The character of coke, it is stated, is open to considerable modification depending on conditions of carbonization. Formerly it was thought that temperature, and in consequence volatile matter, was the governing factor; but recent experience shows that a suitable texture is essential, whether produced by grinding, blending, the incorporation of catalysts, or more obvious methods such as the choice of coal, and thermal treatment. There is insufficient information available at present, both as to the full effect of the numerous factors involved in the carbonization process and on the financial balance-sheet, to permit an opinion as to the comparative value of the different treatments suggested. They offer most promising avenues for technical advancement in the carbonization process.

Speaking of waste heat, the authors state that the application of waste-heat boilers to horizontal retort settings has not been developed to any great extent, though there is here a vast quantity of potential heat available for raising steam, or other purposes. The divorce of the industries of carbonization and electrical power generation is unfortunate, for it impedes developments of this kind which might be mutually advantageous.

Inerts.

Dealing with this question, Dr. Davidson refers to the work of W. Bertelsmann on the influence of inerts in the practical

* Reports of the Progress of Applied Chemistry, issued by the Society of Chemical Industry. Vol. IX.—1924. Edited by T. F. Burton. Price 7s. 6d. to members of the Society, 12s. 6d. to non-members, post-free.

s of gas, which, he says, is calculated to alter the general nion of technical men in Germany, and confirm that of many this country who of late years arrived at the conclusion that objections to the inclusion of inerts in town gas have not en well justified. Bertelsmann compared straight coal gas h mixed gases. Illumination tests proved that thermal ciency was distinctly greater with poor than with rich gases. nen the illumination of an upright incandescent burner was usted to give its maximum candle-power, it was found that s containing about 20 p.ct. of inerts had the same efficiency a hydrogen mixture with practically no nitrogen in it. In ts of the heating of water from 20° to 70° C., efficiencies reased with a decrease in calorific value. In another series tests where calorific value was kept constant and the volume inerts made to vary, it was found that with gases diluted with drogen 96 calories were required to raise 1 kg. of water rough 75° C., whereas gases containing about 21 p.ct. of rts required about 98 calories.

Dr. Davidson considers at some length the three Cantor Lec- res of Mr. E. V. Evans on "A Study of the Destructive stillation of Coal" [see "Journal," Vol. 165, pp. 483, 550, 9]; and his remarks on this take the form of a résumé of e articles which were published in the "Journal" [see Vol. 7, pp. 447, 515, 580.]

Speed of Carbonization.

Speaking of the various patents taken out during the year improve the rate of carbonization and to obtain graded dis- lation in zones, Dr. Davidson mentions the method suggested Green and Laucks, which involves the use of a vertical re- t in which the coal is passed upwards by means of a hollow rew. Simultaneously with the heating of the coal by con- ction through the retort walls, heat is applied to the interior the screw by means of an adjustable burner. The pitch of e screw gradually increases from the lower to the upper end the retort; and the bore of the retort gradually increases from ttom to top, the diameter of the screw varying correspond- gly. Attention is also drawn to T. M. Davidson's proposal have the surfaces of the retort movable, to increase through- t. A vertical or inclined retort has longitudinal sections which e capable of reciprocatory movement, and the products of dis- lation may be taken off by a central tube, which may be raised lowered to any carbonizing zone. The whole retort is divided to lengths of uniformly increasing temperature, and the gases distillation pass in the direction of movement of the coal, nd are withdrawn at or below the highest temperature zone.

Oil Shale For Gas Production.

Many facts and figures with regard to the present position the oil shale industry in Esthonia are contained in a paper ubmitted by Mr. P. N. Kogerman, M.Sc. (Lond.), to the Insti- tion of Petroleum Technologists. Though the Esthonian oil ale, known as "Kukersite," was discovered more than a ntury ago, it was only during the late war that its importance ; a substitute for coal and as a source of gas and oil produc- on came into prominence. At that time, after trials of the aterial on a large scale had been carried out at the Petrograd as-Works, it was decided to embark on an extensive mining heme, which events precluded from being taken actually in nd by the Government until May, 1919. Since then the ex- oitation of the oil shale has continued without interruption; nd the annual output has now reached a very considerable gure. The probable resources are calculated at about 5000 illion tons. The consumption of "Kukersite" as a fuel for l kinds of boilers has been steadily growing; while the gas- orks at Tartu (Dorpat) and Tallinn have partially adopted it or gas production—though for the latter purpose coal is pre- rred because it produces coke and avoids the cost of ash re- oval. The author gives the following as the chemical com- osition of oil-shale gas:

	P.Ct.
Hydrogen	37·6
Methane	25·8
Heavy hydrocarbons	1·6
Carbon monoxide	19·1
Carbon dioxide	13·3
Nitrogen	2·6

n the gas-works named, the material is dealt with in old-type orizontal retorts, which are not altogether suitable for the arbonization of shale. The yield of gas is 10,000 c.ft. per ton; nd of tar, from 4 to 5 p.ct. Several plants for the distillation f shale oil are at work in Esthonia—including an installation f "Fusion" retorts, some figures with regard to which ap- eared on p. 149 of the "Journal" for Jan. 21 last, in con- ection with a paper read by Mr. T. W. Stainer Hutchins at joint meeting of the London Section of the Society of hemical Industry and the Chemical Engineering Group.

North of England Gas Managers' Association.—The annual eneral meeting of the Association will be held on Friday, May 1, at the County Hotel, Newcastle-on-Tyne. Mr. S. Shad- olt, President, will take the chair, and two papers will be read —one by Mr. C. Dru Drury, of Sunderland, on "Some Ex- eriences with Gasholder Tanks in a Mining Area;" the other y Mr. W. M. Galleway, of Whitby, on "Income-Tax Allow- nce for Wear and Tear of Gas-Works Plant."

THE NATION'S FOOD EXHIBITION.

The remark is often heard that life would be simpler and better if a day's supply of food, in the form of compressed tablets of vitamines, proteins, &c., &c., could be carried in the pocket. This plan might have advantages; but when one reflects on the delightful hours spent in human contact at tea or at dinner—the subject of breakfasts need not be dwelt upon here—the idea of tabloid-swallowing loses any attraction it may seem to possess. The mellow sayings of the old philosophers, the brilliant epigrams of the wits of the day, even the broad but kindly jests of the man of the soil—where would they all be, but for the humanizing and stimulating effects of good food and good drink? And in times of stress such as the present, it is good to think that the work of preparing meals has, thanks to the aid of gas, been so lessened that it no longer entails the nervous prostration of the housewife. Realization of this is strengthened by a visit to the Nation's Food Exhibition at Olympia. During the course of a year, Olympia undergoes many transformations. It changes, with the rapidity of a chameleon, from a hall where the latest developments of engineering can be seen to a place where the ideal home can be visualized. At present it is a palace for epicures; and for the sake of the nation's health all should be epicures in respect of food—they should prefer good food to bad. The Nation's Food Exhibition assists the public as to what to buy, where to buy, and what to pay; and visitors are inducted into the very interesting processes of manufacture of the many varieties of foodstuffs.

The "B.C.G.A." Exhibit.

When the present iron-roller system of flour milling was introduced in England about fifty years ago, the English miller claimed that there could be nothing better for grinding wheat than the time-honoured millstones, by the use of which the valuable food constituents of the grain were retained in the meal. The roller system has certainly led to the almost exclusive production of a white flour containing little of these elements. Wholemeal flour, however, as ground in millstones, even with much of the bran sifted out, is somewhat heavy; and this applies particularly to British wheat, which is naturally soft. It would seem, therefore, that there is a necessity for a new mechanical means by which a really pure and satisfactory wholemeal flour can be efficiently and economically produced. With this object in view the "Kek" mill has been specially adapted. It is manufactured by the Chemical Engineering Company, Ltd., of Manchester. This firm show how, with a gas-engine driven mill, good flour can be produced; and the British Commercial Gas Association, on the same stand, demonstrate how efficiently this flour can be baked in the gas oven. The appliances employed for the work are two "New World" raised cookers, and the cakes made are sold to the public. The combined exhibit is excellently arranged, down to the smallest detail. A Richmond water heater is used for washing-up purposes.

Other Exhibits of Interest.

Two exhibits of Messrs. Radiant Heating, Ltd., who show a representative selection of their apparatus, which is well known to gas engineers, are of particular interest. One is a water heating unit. This is in the form of a totally immersed tube, and the gas burns in contact with its own products of combustion. The other is a toaster and griller which is a new departure in that it does not require additional air pressure. The National Gas Engine Company have a 2½-kw. lighting set consisting of a standard National town-gas engine and chain-driven dynamo. The set is supplied with a totally-enclosed silent inverted tooth chain running on machine-cut chain wheels. There is also an "RL" type town-gas engine, embodying all the latest improvements, and capable of developing 32 B.H.P. Messrs. Benham & Sons, Ltd., make a special feature of their "Victor" dish-washing machine, which can be heated by gas This efficient apparatus is installed at the Hotel Cecil, Messrs. Selfridge, Ltd., and many other important establishments, and on many liners. They also show a general range of their gas-fired appliances, including pastry ovens, &c. Gas-fired chip potato ranges and heavy gas ovens are shown by Messrs. Mabbott & Co., Ltd. "Cling-Surface" preparation for belts, enabling them to transmit 100 p.ct. load while running slack, and "Permac" jointing material are exhibited by Messrs. Thomas & Bishop, Ltd. Industrial trucks of all descriptions are shown by Messrs. W. Goodyear & Sons, Ltd.; a special feature being the Goodyear-Greenbat electric truck.

Safeguarding of Gas Mantles.—The Board of Trade have appointed a Committee, consisting of Sir Frederick Mills, Sir John Barran, and Mr. J. Arthur Aiton, to inquire into and report upon an application made by the Incandescent Mantle Manufacturers' Association for the imposition of a duty upon gas mantles. The Secretary to the Committee is Mr. C. K. Hobson, Board of Trade, Great George Street, London, S.W. 1, to whom all communications relating to the work of the Committee should be addressed.

CORRESPONDENCE.

[We are not responsible for opinions expressed by Correspondents.]

Electrical Explosions.

Sir,—In your issue for April 15 there is a paragraph in the Electricity Supply Memoranda dealing with the cause of explosion in cable conduits. Some time ago a possible immediate cause came to my notice; and as I have not seen any mention of a similar case elsewhere, I think it should be put on record. An electrical fitter brought me a small piece of pasty material which he had found adhering to the side of a bricked manhole through which access to a conduit was gained. His attention had been attracted to it when a similar piece, thrown out on to the roadway, had fallen into a pool of water, and apparently given out sparks. On examination I found the paste contained metallic sodium—no doubt from the electrolysis of some sodium salt contained in the materials of the conduit, by stray currents from a fault in the cable. Dropping water on to the mass caused a copious shower of sparks. The effect of such an occurrence on any explosive mixture of gases in a closed conduit requires no further comment.

Arthur Forshaw.

Falkirk, April 23, 1925.

Hiring Charges and Installation Delays.

Sir,—I have read your criticism of electric cookers on pp. 173-4, and am glad to learn that you consider all arrangements made for supplying gas-cookers absolutely perfect.

When you quote the trifling sum of £4 for a gas-cooker, I begin to wonder what kind of gas-cooker it is. I have yet been unable to discover a sample which is at all efficient under £10. In my area, the Gas Company have discarded the hiring system, and the householder must buy the gas-cooker outright, and wait a minimum of three weeks for installation. I think you could devote your energies to the question of delivery dates in the supply of gas appliances, since I, at least, consider that three days is a reasonable period for installation, and not a general average of three weeks. The gas industry, as far as the area in which I live is concerned, only requires a little publicity with regard to its delivery dates to be discredited.

As to the hiring of gas fires, which is a matter you overlook, I find myself saddled with the trifling sum of 32s. per annum for the hire of two gas-fires, which are not at all efficient. You will note that 32s. is equivalent to an interest charge, at a rate of 6 p.ct., on a capital sum of £27. Even allowing for depreciation, you will see that no electric fires can compare with those gas-fires in price. There are few electric fires on the market which cost more than one-sixth of this sum. The gas industry has a long record of profiteering to overcome in the hiring of appliances especially and of inefficiency in installation before it can criticize the electrical industry; and I think you could devote some part of your musings to working conditions in the gas companies of the Metropolis.

Hugh Quigley.

London, April 21, 1925.

[We are not clear as to why our correspondent considers that the criticisms made in "Electricity Supply Memoranda" for April 15 of a paper by Mr. R. Hardie, of Glasgow, gave the impression that we regard as absolutely perfect all arrangements made for supplying gas cookers. Throughout the criticisms there was no indication of such an idea on our part. Indeed, constant readers of the "Journal" know full well that we are frequently pegging-away at gas undertakings which are negligent as to the service they render to consumers, while at the same time praising those go-ahead ones which take a pride in building-up a reputation and permanent business by looking well after the interests of their patrons. As to the price of gas cookers, we were unaware that we gave £4; it was Mr. Hardie who quoted that figure for a gas cooker, and £12 10s. for an electric cooker. Mr. Quigley wonders what kind of gas cooker a £4 one can be, as he has not yet been able to discover one which is at all efficient under £10. We think that, if he applies to any of the well-known makers of gas cookers, they will be able to introduce him to several types which can be purchased for much less than £10. One large maker quotes a little over £3 for single case cookers, and about £6 for double case ones in much better finish. Quite modern cookers, giving the consumer high efficiencies and with modern accessories, can be bought for £7 to £8; and much more expensive ones can be obtained. But there is not at all a bad selection of cookers suitable for hiring purposes which are purchasable at round about the £4 mentioned. If our friend would like a cooker with the oven externally heated, we can introduce him to some at prices ranging between £8 8s. and £10, or higher prices still. The higher prices for modern types are usually due to size, more accommodation, and finish, rather than to a greater thermal efficiency. As to our correspondent's general criticism of the Company supplying in the district in which he resides, any grievance he has is purely a matter for him to settle direct with the Company. But we would suggest to him that he would find it more profitable to purchase outright two good gas fires than to continue paying the rental figure to which he refers. Of course, we do not know the conditions attached to the charge—whether or not it includes the periodical inspection, adjustment, and maintenance of the fires. But as to their being not at all efficient, there is no reason why any gas fire should be in existence which is not giving to the room in which it is used 70 to 75 p.ct. of the heat generated by the combustion of the input of gas. With confidence it can be claimed that we have had personal experience of a greater number of gas fires than our correspondent, and over a course of years no doubt far exceeding his acquaintance with them. We are always able to obtain from them a high degree of efficiency with gas of a calorific value of 500 B.Th.U. per c.ft. Whatever grievances our correspondent has against his own Gas Company should not be used as representing general conditions throughout the gas industry.—Ed. "G.J."]

REGISTER OF PATENTS.

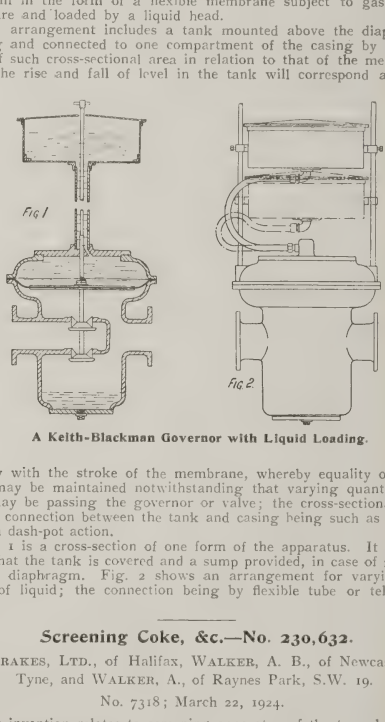
Loading Governors.—No. 230,266.

Keith & Blackman Co., Ltd., and Keith, G., both of Farringdon Avenue, E.C.

No. 5590; March 4, 1924.

This invention relates to a diaphragm loading arrangement for gas governors and other valve apparatus of the type including a diaphragm in the form of a flexible membrane subject to gas or air pressure and loaded by a liquid head.

The arrangement includes a tank mounted above the diaphragm casing and connected to one compartment of the casing by a tube, and of such cross-sectional area in relation to that of the membrane that the rise and fall of level in the tank will correspond approximately with the stroke of the membrane, whereby equality of pressure may be maintained notwithstanding that varying quantities of gas may be passing the governor or valve; the cross-sectional area of the connection between the tank and casing being such as to produce a dash-pot action.



A Keith-Blackman Governor with Liquid Loading.

Fig. 1 is a cross-section of one form of the apparatus. It will be seen that the tank is covered and a sump provided, in case of rupture of the diaphragm. Fig. 2 shows an arrangement for varying the head of liquid; the connection being by flexible tube or telescopic pipe.

Screening Coke, &c.—No. 230,632.

Drakes, Ltd., of Halifax, Walker, A. B., of Newcastle-on-Tyne, and Walker, A., of Raynes Park, S.W. 19.

No. 7318; March 22, 1924.

This invention relates to screening apparatus of the type described in specification No. 8439 of 1914 [abstracted, with drawings, on p. 400 of Vol. 130 of the "Journal."]

The patentees now claim, as modifications, the employment of adjustable fingers and means for securing same so that openings of the sieve may be increased or decreased in width; and the employment of additional finger pieces having slots to permit of their adjustment relatively to the pieces on which they are mounted, and bolts for securing them.

Extraction of Coke from Vertical Retorts. No. 230,518.

Woodall, Duckham, & Jones (1920), Ltd., and Sir Arthur M'D. Duckham, both of Grosvenor Gardens, S.W. 1.

No. 28,529; Nov. 12, 1923.

The patentees point out that one method of governing the issue of coke from the lower end of a continuous vertical retort consists in making the bottom of the retort a separate piece carried in a gas-tight casing by a support capable of vertical reciprocating motion within the stationary casing. According to the present invention the casing is made the reciprocating part, and its bottom the bottom of the retort; the arrangement avoiding the necessity for removing the coke from a gas-tight casing.

The casing which has received its charge of coke is removed from

the retort; and its place is taken immediately by another, or it is emptied quickly and replaced. Inserted bars temporarily support the charge in the retort during the removal of the casing.

Conveniently, the casing also forms the necessary seal for the bottom of the retort. To this end there may be a fixed depending mouthpiece, or extension of the retort, surrounded by a metal curtain, and the vertical walls of the container may be double so as to hold water into which the metal curtain dips.

To prevent the entrance of air into the retort when the container has been removed, steam jets may be provided in the extended portion of the retort, the jets producing a slight pressure.

Purification of Crude Ammoniacal Liquors.

No. 230,705.

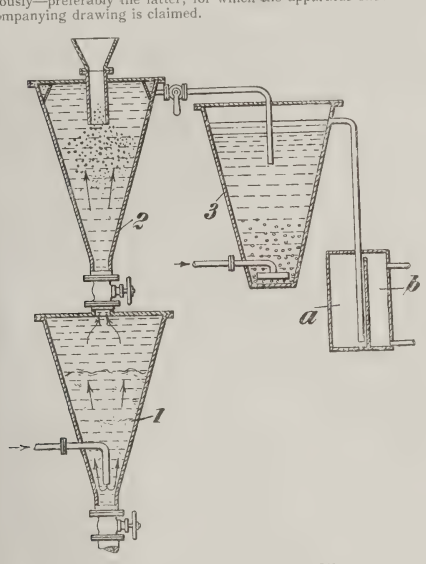
Potts, H. E., of Liverpool.

(A communication from Z. M. Stinnes, of Essen-Ruhr.)

No. 17,742; July 25, 1924.

This invention is for a two-stage process of purification for crude ammoniacal liquor. The tarry matters are first removed and the phenols are then extracted in a substantially pure condition. In the first stage the crude ammoniacal liquor is treated with a solid adsorbent, such as calcium carbonate, alumina, sawdust, wood-charcoal, &c., which fixes and binds the finely divided and suspended tarry drops. The dirty mass thus produced is separated in the usual manner, and the clarified ammoniacal liquor is now, in the second stage of the process, extracted with a solvent such as benzene, preferably at an elevated temperature, whereby the phenols are quickly dissolved. The mixture of the two liquors is allowed to separate under gravity, and from the benzene extract the phenols are obtained in a pure state by distilling off the solvent, while at the same time the benzene is not adulterated by tar and can be used again for another operation without purification.

In practice the process is carried out either intermittently or continuously—preferably the latter, for which the apparatus shown in the accompanying drawing is claimed.



Purifying Crude Ammoniacal Liquor—Stinnes.

The adsorbent is fed into the container 2 by means of a funnel having an elongation. The crude ammoniacal liquor enters the bottom of the container 1 by way of a pipe bent downwards. It continually flows upwards and meets in a counter-current the adsorbent, of which a portion gradually sinks downwards into the container 1. The rate of flow of the liquor is regulated in such a manner that the greater portion of the adsorbent is kept in suspension at about the middle of the container 2, where it adsorbs the tarry matter, together with which it gradually sinks down as a greasy mass into the bottom of container 1, whence it is run off from time to time by opening the bottom valve.

The ammoniacal liquor thus freed from the tarry matter overflows from container 2 into another container 3 of similar shape; the adsorbent being retained in container 2 by a screen or sieve. At the same time benzene in a finely divided state is allowed to rise in pearly drops (by means of a pipe and rose) from the bottom upwards in the container 3, where it extracts the phenols dissolved in the aqueous liquor. The mixture of water and benzene is continually withdrawn and run into the bottom of a tank provided with a division wall, so that the aqueous liquor can overflow from the compartment *a* into *b*, in which latter compartment the separation of the benzene top layer from the aqueous bottom layer is effected. The benzene extract is run off into a collecting tank and thence to a distilling apparatus to recover the benzene (for re-use) and the phenols, while the purified ammoniacal water is carried away and treated for the production of ammonia.

The ammoniacal liquor before entering the top container 3 should be warmed to 40° to 45° C., so that the benzole drops may ascend through the warm water, whereby a great saving of time and benzole is effected.

The waste water from the ammonia stills can then be run into (say) a river, and, being free from tar, phenols, &c., can do no harm to the fishing industry.

Gas Cookers.—No. 230,921.

Helps, G., of Nuneaton.

No. 31,929; Dec. 20, 1923

According to this invention, which has for its object to allow hotplates of a standard size to be used for cookers of varying size, a hotplate with its burners forms a separate entity, detachable from the cooker, and is so carried by a base plate, a frame, or two strips, that it can rest on the cooker, to which it may be secured by screws. The hotplate may be so supported on the base plate, frame, or strips as to provide a channel in which a crown plate can slide.

The arrangement allows a large hotplate to be conveniently supported from the top plate of a small cooker, or a small hotplate to be supported on a larger cooker, and in each case fixed in a few moments.

LEGAL INTELLIGENCE.

EXTRACTION OF TOLUOLE.

Dr. Davidson's Claim on the War Office.

On Monday the Royal Commission on Awards to Inventors (presided over by Mr. Justice Tomlin) heard a claim by Dr. W. B. Davidson for compensation by the War Office in respect of processes for the extraction of toluole from coal gas. Mr. Whitehead, K.C., and Mr. James Mould appeared for the applicant; Mr. Courtney Terrell and Mr. D. H. Corsellis represented the War Office.

Mr. Whitehead said the claim was made under clause 3 of the Royal Commission by the applicant, William Brown Davidson, who was a gas engineer, a consulting chemist, a Doctor of Science, a Doctor of Philosophy, and a Fellow of the Institute of Chemistry. At the time the process was evolved which was the subject of the claim, he was with the Birmingham Corporation. Some time ago there was presented to the Commission a claim on behalf of Dr. Rother and Dr. Palmer, who were employed at the Royal Arsenal, Woolwich, in respect to the manufacture of "T.N.T.;" but the Commission took the view that their status debarred them from obtaining a reward. In the course of that claim, it appeared that the first steps with regard to the manufacture of "T.N.T." were taken quite early after the outbreak of war; and no sooner did it become plain that there was a chance of manufacturing toluole on a large scale, than it became evident that the supply of toluene would have to be considerably increased. This was recognized at the Royal Arsenal; and Dr. Rother at the beginning of November, 1914, communicated with Dr. Davidson with regard to the best means of adding to the supply of toluene. Various suggestions were made by letter, and Dr. Davidson's opinion was asked as to the possibility of obtaining toluene by synthetic processes. In reply, Dr. Davidson criticized the suggestion made; but after thinking about the matter, he evolved the process in question on Dec. 28, 1914. Dr. Palmer was not satisfied with the work; but he thought it was his duty to bring it to the notice of his Chief, and the matter was submitted to Lord Moulton. On Jan. 11, 1915, Dr. Davidson was sent for by Lord Moulton, to whom he explained the process. Lord Moulton was favourably struck with the scheme, because a little later he telegraphed to Dr. Davidson, and arranged for a meeting to be held at the Grand Hotel, Birmingham, at which Sir H. Rogers (the Chairman of the Gas Committee) and Captain R. S. Hilton (the Secretary and Manager) were present. The process was fully discussed, and

in the result the applicant was asked to arrange for the erection of plant at the Nechells Gas-Works. Applicant was also asked to visit the gas-works at Manchester, Sheffield, Coventry, and other towns, to explain the scheme; and Captain Hilton was directed by Lord Moulton to speed-up the erection of the necessary plant at the different works, in order to carry out the process. It took 3½ months to erect the plant at Nechells, where afterwards the process was carried out. When it was working, it was visited by many English and French gas engineers, with the view of their adopting a similar plan. Dr. Davidson also, at the request of Lord Moulton, proceeded to various parts of the country to give his help and advice with regard to the erection of plant and its working; and he received his travelling and hotel expenses for that work from the Government. The real problem was to obtain as much toluene as possible from the coal gas, and yet to supply a gas which would not be substantially impoverished either with regard to calorific value or light-giving properties. He might mention that no patent had been taken out in respect of the process in question. Counsel produced a diagram, and explained how the process was carried out. He said there was no part of the process, except one, which had not been anticipated; but no one had ever previously carried out the process in its entirety.

Mr. Terrell asked that the invention should be defined, in order that he might deal with it. At present he did not know what it was.

The President understood it consisted of the entire process indicated on the diagram.

Mr. Whitehead said that was so. In order to perform the work, a number of things had to be carried out which involved an immense amount of research work. This was done by Dr. Davidson at his own expense and in his own time.

The President said no claim for expenses could be substantiated in respect of this, except so far as it was incidental to some other claim.

Mr. Whitehead agreed that this was so. The claim made in respect of expenses and research work was £510.

The President pointed out that the actual out-of-pocket expenses had been paid. It might be that Dr. Davidson was not free to contract with the Government, as his services belonged to the Birmingham Corporation. For aught one knew, it might be that the Corporation lent Dr. Davidson to the Government, and put up with the loss of his services on the footing that his out-of-pocket expenses were paid.

Dr. *W. B. Davidson* was then called, and gave evidence in support of his claim. He said the experiments were done at the works in his own time, and he expended considerable sums on apparatus and chemicals. He had never received anything from the Birmingham Corporation in respect of this work.

The hearing was adjourned till Monday next.

MISCELLANEOUS NEWS.

GAS REGULATION ACT APPLICATIONS.

The following notice has appeared in the "London Gazette" regarding an application to the Board of Trade under the Gas Regulation Act.

SPECIAL ORDER

Bollington Urban District Council.

The Council intend to apply to the Board of Trade for an Order under section 10, to extend their gas supply limits, to authorize the purchase of additional lands, to enable them to charge on the thermal basis, and for other purposes.

TRAGEDY AT NEWPORT.

No Blame Attached to Gas.

On Monday, April 20, an inquest was held at Newport (Mon.) on Mr. F. Vaughan, a well-known Newport and Cardiff solicitor, and his wife, who were found dead in their bedroom on April 16. The tragedy was discovered by Dr. R. W. Haslett, who had for some time been attending Mr. and Mrs. Vaughan for heart trouble, at three o'clock in the afternoon. In giving evidence, Dr. Haslett said that, when he called at the house, the maid told him that deceased were asleep. On entering the bedroom, however, he discovered that they were dead. A gas fire, fully alight, was burning in the room, which was very oppressive; the air temperature being no less than 115° Fahr. Dr. V. A. Crinks, who conducted the post-mortem examination, gave the opinion that death was due to asphyxia from carbon-monoxide poisoning.

Mr. J. H. Canning, the Engineer and Manager of the Newport Gas Company, said that on Friday, April 17, he examined the gas fire, and found it in perfect order. The top of the fire was covered with a deposit of what appeared to be mortar, and a similar deposit lay on the hearth. He tested the chimney for draught, and found it inoperative. The flue was then inspected, and an obstruction was found some 12 ft. above the hearth. This consisted of two or three bucketfuls of sticks, twigs, fine mortar, clay, and the skull of a bird. The latter indicated that a nest had been in the chimney for some time. The nest could not, however, have actually sealed the flue; for on March 11 the fire was examined by one of the Company's fitters, and the chimney draught at that date was perfect. The blockage was probably caused by mortar falling from the portion of the flue above the nest, and closing all the small openings.

The Coroner, Mr. W. Lyndon Moore, D.L., J.P., said that it was satisfactory to know that death was not due to the fault of anyone, but was rather the neglect of the old rule which told them to keep their chimneys clean. It was clear that on March 11 there had been a proper current of air ascending the chimney. No doubt the opinion advanced by Mr. Canning was a sound one.

The foreman of the jury intimated that they were unanimously of the opinion that death was due to misadventure.

METROPOLITAN GAS COMPANIES' OFFICIAL TESTINGS.

The Gas Referees' reports of the official testings for the past quarter give the following average calorific values for the gas supplied by the Metropolitan Companies named.

Brentford Gas Company.—501·3 B.Th.U. (declared calorific value, 500 B.Th.U.).

Commercial Gas Company.—476·8 B.Th.U. (declared calorific value, 475 B.Th.U.).

Gas Light and Coke Company.—501·8 B.Th.U. (declared calorific value, 500 B.Th.U.).

South Metropolitan Gas Company.—562·6 B.Th.U. (declared calorific value, 560 B.Th.U.).

South Suburban Gas Company.—501·5 B.Th.U. (declared calorific value, 500 B.Th.U.).

Tottenham District Light, Heat, and Power Company.—503·7 B.Th.U. (declared calorific value, 500 B.Th.U.).

Wandsworth, Wimbledon, and Epsom District Gas Company.—474·5 B.Th.U. (declared calorific value, 470 B.Th.U.).

BOMBAY GAS COMPANY, LTD.

The report of the Directors, which will be presented at to-day's meeting of the Company, shows a profit of £21,761, which, added to the profit on exchange, £5185, and the balance of £35,051 brought forward from the previous year, amounts to £61,997. After providing for the payment of interest, &c., and the interim dividend paid in November last, and the addition of £1404 to the reserve fund, £997 to the renewal fund, and £184 to the insurance fund, there remains a balance of £46,208, out of which the Directors recommend the payment of a dividend of 4 p.ct. (less income-tax), making 8 p.ct. for the year, which will leave £34,208 to be carried forward to the current year. The Directors announce with profound regret the death of their esteemed colleague and friend, Mr. Henry Edward Jones. They place on record their deep appreciation of the important and valuable services which he rendered to the Company as a Director for a period of 33 years—for 21 years of which he was Chairman of the Board—and their sense of the loss which the Company have sustained by his death. Mr. Stanley Hunter Jones, M.Inst.C.E., has been appointed to fill the vacancy on the Board. Mr. A. R. Burch, the Company's Engineer and Manager in Bombay, resigned his office in October, 1924, owing to ill health. He was the Company's representative in Bombay for 18 years, and fulfilled the duties of his office to the entire satisfaction of the Directors and with great advantage to the Company. They have appointed the Deputy Engineer and Manager, Mr. W. T. Lane, in his place. It is intended to increase the nominal capital of the Company by the creation of new ordinary shares of £1 each.

CURRENT SALES OF GAS PRODUCTS.

The London Market for Tar, Tar Products, and Sulphate.

London, *April 27.*

Pitch continues without material change. There is still a moderate amount of inquiry for this season's delivery: but buyers' ideas of value are low. The price to-day is nominally 41s. to 42s. per ton f.o.b. works. There is a certain amount of interest being taken already in business for next season.

Creosote is quietly steady at about 7d. per gallon net and naked at makers' works.

Pure benzole and pure toluole remain at about 1s. 10d. per gallon.

Solvent naphtha, 95/160, is firm at about 1s. 8d. per gallon.

Tar Products in the Provinces.

April 27.

The average values for gas-works products during last week were: Gas-works coal-tar, 27s. 9d. to 32s. 9d. Pitch, East Coast, 40s. to 41s. f.o.b. West Coast—Manchester, 35s. to 36s.; Liverpool, 36s. to 37s.; Clyde, 39s. to 40s.; Benzole, 90 p.ct., North, 1s. 6¼d. to 1s. 7¼d.; crude, 65 p.ct., at 120° C., 10d. to 1s., naked at makers' works; 50-90 p.ct., naked, North, 1s. 6¼d. to 1s. 7¼d. Toluole, naked, North, 1s. 6¼d. to 1s. 7¼d., nominal. Coal-tar crude naphtha, in bulk, North, 7½d. to 8¼d. Solvent naphtha, naked, North, 1s. 5d. to 1s. 6d. Heavy naphtha, North, 1s. to 1s. 2d. Creosote, in bulk, North, liquid, 6d. to 6¼d.; salty, 5¾d. to 6¼d.; Scotland, 5¾d. to 6d. Heavy oils, in bulk, North, 6¾d. to 7d. Carbolic acid, 1s. 5d. to 1s. 6d. prompt. Naphthalene, £11 to £14; salts, £4 to £5, bags included. Anthracene, "A" quality 2½d. per minimum 40 p.ct., purely nominal; "B" unsaleable.

Successful Capital Issue at Barnet.—With regard to the sale by tender of £15,000 of "D" capital gas stock of the Barnet District Gas and Water Company, which was recently advertised in our columns, it may be mentioned that the stock was applied for more than twice over; the prices tendered ranging from £116 to £110 per £100 of stock. The average price realized was £112 1s. 10d., and the lowest price to receive allotment £111.

NORTH-EAST COAST COAL TRADE.

From our Own Correspondent.

There has been, if anything, a slightly brighter feeling in the market during the past week, but without very much change in prices. It may be due, in some measure, to the Easter holiday of the previous week, or in some cases—for instance, that of coking coals—to a small increase in prompt inquiry combined with the limitation of output. It will be difficult for prices to rise much on the latter score, because so many collieries are closed, or working short time, which could open out and produce more coal if better prices were obtainable.

There is little news of the doings of the Joint Committee, except the disparaging remarks of the Miners' Secretary. It appears that their sittings are not yet concluded. At any rate the two parties can hardly have failed to agree about the seriousness of the situation.

As already mentioned, there has been slightly better inquiry for prompt shipments of coking coals, and unscreened makes have been firmer at 17s. 6d. to 17s. 9d. for good qualities. Gas coals, however, have shown an easier tendency. Wear Specials quote 19s. 6d. to 20s. f.o.b., but for prompt tonnage there is little difficulty in obtaining them at 19s. The same applies to best qualities, which quote 19s. 6d. to 19s. 9d. Seconds are nominally 17s., and, while some makes are steady at this price, others are obtainable at 16s. 6d. Durham unscreened bunkers are unchanged at about 18s. for best qualities.

COAL TRADE IN THE MIDLANDS.

From our Local Correspondent.

Stocks at the pithead do not seem to have been appreciably relieved as a result of the Eastertide suspension. A few collieries in the district are working full time; but their activity is due to exceptional conditions, output over the whole area being on a decidedly lower scale than before the holidays. The market outlook is exceedingly dejected. Values generally are unstable. Pressure to sell causes great irregularity of prices. Buyers can pick up odd lots at bargain rates; but there is such an utter lack of confidence that speculation is smothered. The only firm features are D.S. nuts and slacks. Price consolidation there is due not to expansion of demand but to contraction of supply owing to the drying-up of the house coal trade. Nuts and slacks command substantially better prices than could be got when the domestic trade was more active.

Blast-furnace coke is in very slow sale. Following the suspension of a basic furnace in South Staffordshire, a Derbyshire furnace which has been smelting foundry pig is being stopped; so that there will be a further displacement. Coke can now be bought at 14s. to 15s., though the basis for the current quarter under the stabilization arrangement is 15s. 9d. The first step is being taken to transfer labour from the Holly Bank pits on the confines of the Black Country to the new electrified Hilton main, where the chief concentration will be henceforward. The decision to close down the Great Wyrley Colliery in the Cannock Chase coalfield is now being given effect to.

YORKSHIRE AND LANCASHIRE COAL TRADE.

From our Local Correspondent.

Gas coals in Yorkshire and Lancashire are not in so big a demand as they were a few weeks ago, and there are indications of a reduction in price when contracts are renewed for the next twelve months.

House coals remain fairly steady, and so far prices have not been disturbed to any great extent. Very little alteration in prices is anticipated during the early summer months, owing to the irregular working of collieries.

There is no improvement in the demand for industrial fuel; and although prompt supplies of the lower grade kinds are on offer at low figures, consumers generally are unable to take advantage of this owing to their contract obligations. There is not likely to be an alteration in this direction for some time. The majority of the larger centres report no progress. In Lancashire, there is a fair demand for the best qualities of slacks; but the commoner kinds are down to about 11s. per ton. Prices at the Lancashire pits are unchanged, and no alteration is probable until after June.

The slump in export fuel still continues, although some collieries are endeavouring to meet the situation by accepting low prices; but it is a question whether this can be continued for long, owing to the heavy costs of production.

Prices at Hull at the week-end were: Bunker and export coal, f.o.b. usual shipping ports. South Yorkshire: Hards, Association, 19s. 9d. to 20s. 6d.; screened gas coal, 19s. to 19s. 6d.; washed trebles, 20s. 6d.; doubles, 17s. 3d. to 17s. 9d.; singles, 17s.; smalls, 13s. 3d.; unwashed doubles, 15s. 9d. to 16s. 3d.; rough slack, 10s. 6d. to 11s.; smithy peas, 20s. to 20s. 6d. per ton. West Yorkshire: Hartley's, 17s. to 18s.; screened gas coal, 18s.; washed trebles, 18s. 6d.; doubles, 17s. 6d.; singles, 17s.; smalls, 12s. 9d.; unwashed trebles, 18s.; doubles, 13s. to 13s. 6d.; rough slack, 10s. 3d. to 10s. 6d.; coking smalls, 9s. 6d. to 10s. 6d. per ton. Derbyshire and Notts: Top hards, 17s. 6d. to 19s. 9d.; washed trebles, 17s. 9d.; doubles, 17s. 6d. to 18s.; singles, 17s.; smalls, 12s. 9d.; unwashed doubles, 15s.; rough slack, 10s. 6d. to 11s. per ton. Yorks, Derby, and Notts: Screened steam coal, 15s. to 17s.; gas coke, 22s. to 23s. 6d.; furnace coke, 17s. to 17s. 6d. per ton.

Cardiff Gas Company's Athletic and Social Club.—The fourth annual meeting of the Club was held on Friday, April 24. In the Secretaries' report reference is made to the excellent work which the late Mr. George Clarry did for the Club. The report goes on to say that they "are fortunate to have secured, to fill the vacancy of President, Mr. H. D. Madden." The accounts were closed on March 31; and the balance-sheet shows the substantial sum of £228 to the credit of the Club. The meeting was held at the Grand Hotel; and after the business proceedings a musical programme was enjoyed.

TRADE NOTES.

"Gas Cookers for 1925."

Stoves, Ltd., of Scotland Road, Warrington, have recently issued a new catalogue bearing this title. The cover is most attractive, and is in keeping with the appearance and quality of their cookers.

Tar Plant for Dewsbury.

The Gas Department of the County Borough of Dewsbury, on the recommendation of their Engineer and Manager, Mr. H. L. Bateman, have placed an order with the Woodall-Duckham Vertical Retort and Oven Construction Company (1920), Ltd., for a tar dehydration plant (T.I.C. lead bath), to produce tar to the Road Board specification. The plant has a capacity of 10 tons a day.

Pyrometers.

The Bowen Instrument Company, of No. 9, Newton Road, Leeds, have published two pamphlets in which are described the "Pyro" insertion pyrometer and an electrical pyrometer designed to measure the temperatures of type-metal in printers' casting plants. The "Pyro" instrument is designed for workshop use in aluminium and non-ferrous foundries, in which there has been a great demand for a rapidly operating pyrometer.

The New Gladstone Dock.

Messrs. Stothert & Pitt, Ltd., of Bath, have received an order for 27 electric jib cranes of their latest pattern crank-operated horizontal luffing type. Nineteen of these will have a lifting capacity of 3 tons at 74 ft. 9 in. radius, or 1½ tons at 85 ft. 9 in.; and the other eight cranes will deal with 1 ton at 48 ft. 6 in. radius. These 27 cranes, together with 31 similar ones which the firm are now building, form the complete equipment of the new Gladstone Dock.

The Automatic Light Controlling Company, Ltd.

The Bournemouth Corporation have just agreed to renew their contract with the British, Foreign, and Colonial Automatic Light Controlling Company, Ltd., of No. 100, Holdenhurst Road, Bournemouth, for a further term of five years, for the hire of "Gunfire" controllers. Their first contract was in 1900, when the number was 162. The contract has been continuously renewed, and the number has increased till now it is between 3000 and 4000. This does not include nearly 2000 used by the Bournemouth Gas and Water Company. The town of Luton have recently placed an order for "Gunfire" controllers.

The "Du-Ex" Expansion Nipple.

The "Du-Ex" (double expansion) nipple, manufactured from specially-drawn steel tubing, is a short length of tube so machined as to form two annular internal beads. These occur at the end which is to be inserted in a tapped main. The lower bead is located at the extremity of the nipple, so that, when expansion takes place, the nipple will be riveted inside the main. The upper head is at such a distance therefrom that the nipple will also be expanded or riveted on the outside of the main. The intervening diameter is thereby pressed outward by this dual expansion; and thus the screwed portion of the nipple, which fits into the main, is so tightened that perfect contact of the threads is assured. A booklet describing this nipple has just been published by the manufacturers—Messrs. J. Stone & Co., Ltd., of Deptford, London, S.E. 14. (London Office: Oceanic House, No. 1a, Cockspur Street, S.W.1.)

CONTRACTS OPEN.

Coal.

Tenders are invited by the County Borough of Dewsbury for the supply and delivery of 16,000 tons of gas coal and nuts. [See advert. on p. 327.]

The Silsden Urban District Council require tenders for the supply of 2600 tons of gas coal covering a period of twelve months. [See advert. on p. 327.]

The Gas Committee of the Congleton Corporation are inviting tenders for the supply of 6000 tons of washed gas nuts or beans. [See advert. on p. 327.]

Tenders are invited by the Sidmouth Urban District Council for the supply of about 3000 tons of Yorkshire screened coal for their gas and electricity works. [See advert. on p. 327.]

The Gas Committee of the Nantwich Urban District Council are prepared to receive tenders for their requirements covering twelve months of screened gas coal and washed gas slack or nuts. [See advert. on p. 327.]

EXTENSIONS.

Telpher Plant at Chesterfield.

The Chesterfield Gas Committee have decided to extend the telpher track in connection with the new retort installation at the Central Gas-Works, at an estimated cost of £186.

Extensions at Oswaldtwistle.

At a meeting of the Oswaldtwistle Council on April 23, Mr. R. Dawson (the Chairman) said that among the new schemes which the Council would have to tackle during the coming year was an extension of the gas-works, at a cost of £21,000.

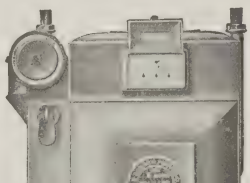
City of Santos Improvements Company, Ltd.—The annual meeting of the Company was held on Wednesday, April 22—Mr. N. B. Dickson, M.Inst.C.E., presiding. Referring to the gas undertaking, he said that the reduction in the price of gas had benefited the receipts. During the year, 357 additional heaters, and 71 water heaters, were connected. There was a strong demand for residuals; and good prices were realized. Residuals returned 47·89 p.ct. of the cost of coal, as compared with 46·31 p.ct. in 1923. The working results were more encouraging than for some years past; and they anticipated better results for the current year, provided there was no appreciable fall in exchange.

THE

OLD VICTORY,

AND THE

NEW—



BOTH SUPREME!

SAWER & PURVES,

MILES PLATTING, MANCHESTER.

RADFORD ROAD, NOTTINGHAM.

45-47 WESTMINSTER BRIDGE RD., LONDON, S.E.1.

Metrogas Operatic Society.

The members of the recently formed Metrogas Amateur Operatic Society are to be congratulated on the success which attended their third production. The selection on this occasion was Gilbert and Sullivan's "Iolanthe," by permission of Mr. D'Oyly Carte; and the hall of the Co-Partnership Institute at the East Greenwich Works of the South Metropolitan Gas Company was taxed to its limit to accommodate the audiences during the four performances—on Wednesday, Thursday, Friday, and Saturday of last week. The caste (all the members of which, together with the Producer and Musical Director and the orchestra, are employees of the South Metropolitan Gas Company) was well selected; and their excellent rendering met with an enthusiastic and much applauded reception throughout. At the concluding performance on Saturday, the principal lady members of the caste were the recipients of numerous floral and other tributes.

Debenture Stock for Haywards Heath.—Among the advertisements in this issue will be found an offer by Messrs. A. & W. Richards for sale by tender of £12,000 of 5 p.ct. perpetual debenture stock of the Haywards Heath District Gas Company. The minimum price of issue is £95 per £100 of stock; and the latest time for the receipt of tenders is Thursday morning, May 7. The money is required in connection with the recent purchase of the undertaking of the Cuckfield Gas Company, Ltd.

Budleigh Salterton Gas Company.—At the annual meeting of the Budleigh Salterton Gas Company, the report and accounts were adopted. The growth of the Company in every direction was referred to by the Chairman, who said more gas was sent out now than had ever been recorded in the history of the undertaking. There was every prospect of continued expansion, as the district served was becoming very popular as a residential area. The price of gas had been reduced by 1d. per therm. He did not think the shareholders had any cause for anxiety as to the effect of the electric competition in the town.

Gas Main Extensions at Carlisle.—Extensions of Carlisle gas mains to Dalston and Burgh-by-Sands are much appreciated by the inhabitants, who, according to a communication to the "Daily Chronicle" by their special correspondent, will receive gas at 3s. 6d. per 1000 c.ft. Mr. J. P. Buck (the Chairman of the Gas Committee) points out that even at Burgh there are already 61 consumers in the village, and of these more than one-half have cookers or gas fires. Between Burgh and Carlisle lies Kirkandrew, where 16 of the householders take gas. In Dalston 78 of the householders have taken a supply; and of these, 29 have had cookers fitted, and 16 gas fires. Mr. Buck looks for excellent results from the extension of the supply to these outlying villages.

Improved Results at Llandudno.—The question of an increase in salary to Mr. H. Duxbury, the Gas Manager, came up for discussion at a meeting of the Council last week, when it was proposed by one member that the question be referred back. Mr. J. E. Payne, supporting the increase, said that in 1920 there were dark days in the gas concern, which led them to spend £61,000. They had a cheeseparing policy in those days, and did not consider the Manager. The output of gas since that time had largely increased, and the leakage had been reduced from 11·36 to 7·84 p.ct. Mr. R. C. Baxter (the Chairman of the Gas Committee) said that they were making more gas from less coal. In the past they had spent hundreds of pounds on expert advice, and in Mr. Duxbury they had a man who was clever at his work. The recommendation was adopted.

Welsbach Light Company's Dinner.—On April 17 the annual dinner given to the outside representatives, depot managers, and departmental managers of the Welsbach Light Company, Ltd., was held at the Caledonian Salon, Holborn Restaurant; and the evening proved a tremendous success. Mr. J. R. Yates, the Chairman of the Company, was in the chair, supported by Mr. H. Talbot, the General Manager. A special menu card which had been compiled by Mr. R. H. Palmer caused great amusement, and resulted in creating that atmosphere of conviviality which is so essential to the success of such functions. Embodied in the menu were many extremely humorous advertisements and a column of personal references entitled "Things we would like to know." After dinner the members were entertained to a concert. Interspersed with the musical programme were several speeches; the one given by the Chairman being especially happy. From the various remarks it was obvious that a great feeling of co-operation exists between all members of the firm. Everyone seems to be imbued with the one idea of making each year more successful than the last as regards the firm's prosperity.

The annual report of the Dalton gas undertaking shows that the make of gas has increased during the past year to 18,963,300 c.ft. The amount of gas unaccounted-for was 2,910,800 c.ft., compared with 1,059,500 c.ft. last year.

The annual financial statement issued by the Darwen Corporation shows a loss of £3256 on the gas undertaking, as compared with a profit of £3002 a year ago. The price of gas has remained at 3s. 8d. per 1000 c.ft. throughout the year.

At a meeting of the Clitheroe Town Council on April 22 Mr. J. Boothman, Chairman of the Finance Committee, said the capital account of the gas undertaking was £99,000. Of this, £55,000 had been paid-off out of profits, and there was also £17,000 invested in sinking fund; the present net indebtedness on the works being £18,000.

Two old servants of the Portsea Island Gas Light Company, having reached the extended age limit of 70, have, under the Company's new pension scheme, just retired—Mr. W. Heath after forty years' service, and Mr. J. Martin after thirty. At the Flathouse Works recently, Mr. Mills (the Works Superintendent) expressed the wishes of all for the health and happiness of Messrs. Heath and Martin. To each he presented a cosy easy chair, as a mark of the regard of the Engineer (Mr. T. Carmichael) and all at the Flathouse Works.

STOCK MARKET REPORT.

STRICTLY cheerful conditions prevailed on the Stock Exchange last week, and there was appreciable increase in the volume of business transacted. The absence of alarums and excursions doubtless accounted for the confidence which prevailed. No effect was noticeable on the declaration of the new French Government, but subsequent events both in France and in Germany may still have far-reaching results.

It is rumoured that another effort will be made shortly to reduce the heavy burden of the 5 p.c. War Loan. It is expected that a further offer of conversion to a longer-dated loan will be made, carrying interest at a rate below the 4½ p.c. rate of last year's offer. The prospects, in view of the dearer money at the present time, depend entirely on the price at which the conversion will be made. No further announcement has, at the time of writing, been made regarding the £3,000,000 Birmingham Loan which is to carry interest at 4¾ p.c., but it is expected that the price will be on the high side.

Quotations at :—*a.*—Bristol. *b.*—Liverpool. *c.*—Nottingham. *d.*—Newcastle. *e.*—Sheffield. * Ex. div.

Investment stocks benefited from Budget expectations of a decrease in the rate of income-tax. Should some relief be given, the Stock Exchange can hardly fail to derive considerable advantage therefrom. Home Rails were much steadier, although still under the cloud caused by the reduced traffic receipts. In the Industrial Market there was a distinct revival, and several sharp rises occurred.

Transactions in the Gas Market were heavier than usual. Of the quotations, Uxbridge 5 p.c. preference rose 2 points, but the remaining changes were on the downward scale. Gas Light ordinary were again marked down by 1½ points. Several capital issues were announced during the week: North Middlesex Gas Company £16,000 Ordinary Stock at £117 10s. minimum; Littlehampton Gas Company £5000 6 p.c. Redeemable Debenture Stock minimum par; Ashton Gas Company £40,000 5¼ p.c. Perpetual Debenture Stock at par.

The following transactions were recorded during the week:

On Monday, Aldershot 4 p.c. preference 73, Alliance and Dublin 66½ *ex* div., British 112, Commercial 4 p.c. 86½, 87, 3½ p.c. 87, 3 p.c. debenture 58½, European 7, Gas Light and Coke 86¼, 86¼, 86⅜, 87½, 4 p.c. preference 79, 79⅜, 3 p.c. debenture 62, Imperial Continental 182, Primitiva 10s. 1½d., 10s. 3d., 10s. 4½d., 10s. 6d., 10s. 9d., 11s., South Metropolitan 94½, 6½ p.c. debenture 103 5/16, South Suburban 5 p.c. 98. Supplementary prices, Brighton and Hove 6 p.c. "B" preference 106, Dover 5¾ p.c. debenture 102⅜, Gas Light and Coke 10 p.c. bonds 196½, Leatherhead new 4 p.c. debenture 76.

On Tuesday, Alliance and Dublin 67, 67¼ *ex* div., Bombay 5 1/16, British 110, Continental Union 35, European 7, Gas Light and Coke 86, 86⅛, 86⅜, 87, 3 p.c. debenture 61, 61½, Imperial Continental 180, 180½, Primitiva 10s., 10s. 3d., Sheffield "C" 102¼, 102⅜. Supplementary prices, British, Hull, 4 p.c. mortgage debentures 72, 72½.

On Wednesday, Bombay 5 1/16, 5 1/16, Brentford "B" 95, Commercial 4 p.c. 87½, Continental Union 35, 7 p.c. preference 89, 89⅜, Gas Light and Coke 85⅜, 86, 86⅛, 86½, 86⅜, 86⅜, 3½ p.c. maximum 63⅜, 64, 3 p.c. debenture 61⅜, Imperial Continental 180⅜, Primitiva 10s., 10s. 3d., 10s. 4½d., 10s. 5¼d., San Paulo 6 p.c. preference 8¼, South Metropolitan 94½, 95, South Suburban 5 p.c. 97. Supplementary prices, Gas Light and Coke 10 p.c. bonds 196¾.

On Thursday, Bombay 5¼, Brentford "B" 98, Continental Union 35¼, 35⅜, European 7½, Gas Light and Coke 85⅜, 85⅞, 86, 86⅛, 4 p.c. preference 70½, 80, 3 p.c. debenture 60⅜, 61¼, 61⅜, Imperial Continental 180, 181, 181½, Primitiva 10s., 10s. 4½d., 10s. 6d., South Metropolitan 94, 94½, 95, 95¼, South Suburban 5 p.c. 97, 98. Supplementary prices, Brighton and Hove 6 p.c. "B" preference 107¾, Gas Light and Coke 10 p.c. bonds 196½, Liverpool 5 p.c. 86⅞, 87¼.

On Friday, Bombay 5¼, Brentford "B" 95, 96, British 112, Commercial 4 p.c. 86½, 87⅛, 3½ p.c. 86½, Gas Light and Coke 85⅞, 85⅞, 86, 86⅛, 4 p.c. preference 79, 79⅓, 79¼, 3 p.c. debenture 61, 61½, Imperial Continental 180½, Liverpool 7 p.c. preference 104⅜, 105, Primitiva 10s., 10s. 7½d., South Metropolitan 94¼, 94½, 3 p.c. debenture 61, Swansea 7 p.c. preference 102, 103, 6½ p.c. debenture 103⅜, 104⅜, Uxbridge, Maidenhead, 5 p.c. preference 95½, Wandsworth 3 p.c. debenture 58. Supplementary prices, Wandsworth 3½ p.c. new 97½.

Money was scarce in Lombard Street during the week, but towards the close the demand was not particularly keen. Rates remained high, however. Although old day-to-day loans were renewed at 4 p.c., as much as 4½ p.c. had to be paid for new money, but a few balances were obtained at cheaper rates. Again no Treasury Bonds were allotted, and the rate at which the Bills were allotted was £4 4s. 9·66d. p.c., being 7·28d. p.c. above last week's average.

Sterling was the centre of interest on the Foreign Exchange market. The New York rate went to a fresh high level on Friday at 4.81⅛, and the prospects of reaching parity were again revived. French francs closed at 92.52½, Belgian francs at 95.12½, and Italian lire at 117.

Silver was dull, the quotation declining ⅛d. to 31 1/16d. per oz. Gold was 86s. 3d. per oz.

The Bank Rate is 5 p.c., to which it was raised from 4 p.c. on March 5. Bankers' deposit rates are 3 p.c. The deposit rates of the discount houses are 3 p.c. at call and 3⅛ p.c. at notice.

The price of gas has been reduced in Withnell and Brinscall from 4s. 6d. to 4s. 3d. per 1000 c.ft.

The Wakefield Electricity Department are boosting electric cooking by reduced prices of all electricity, but especially for cooking and heating; by the hire of cookers at 7s. 6d. per quarter (for cooker for 4 to 6 persons) and 10s. (for 6 to 10 persons)—the hire charge including delivery and fixing of cooker and switchboard, an electric kettle, and maintenance of the whole apparatus, subject to fair wear and tear. Domestic heating charges are 1d. per unit where a cooker is installed, as against 1¼d. otherwise, and 5d. to 6d. per unit (according to quantity) for lighting.

The Directors of the Oriental Gas Company, Ltd., have resolved to pay, on May 30, an interim dividend at the usual rate of 3½ p.ct., less income-tax, on account of the year ending on June 30 next.

At Blackpool, on April 23, Mr. J. H. Chew, Gas Engineer and Manager, reported that during the year ended March 31 ten miles of gas mains were laid and 1689 new consumers connected, compared with 5½ miles of mains and 1084 consumers for the previous year. The Easter output was just under 20,000,000 c.ft.—an increase of 2½ million c.ft., or 14½ p.ct. During the five weeks ended April 25 the output was 85⅝ million c.ft.—an increase of 6⅜ p.ct. During the month 150 new consumers were connected, against 95 a year ago.

EDITORIAL NOTES.

The Budget and Industry.

SINCE the Chancellor of the Exchequer (Mr. Winston Churchill) made his famous speech last Tuesday week outlining his fiscal proposals, they have been the primary subject of consideration and discussion throughout the country. The immediate effect of the revelation of a clever piece of financial construction was gratification and applause. But in a few hours the country had been led into a new channel of thought; and it was then seen that, so far as those large sections of industry and commercial enterprise which give considerable employment are concerned, what the Chancellor gave away with one hand he, at any rate in part, withdrew by the other. In short, there is comparatively little in the Budget which will assist, encourage, and inspire industry. Industry and trade would have been better pleased with the sixpenny reduction from the standard rate of income-tax had there been nothing to discount it. The individual payer of income-tax who has to pay only on earned income, or on interest and dividends which are derived from investment sources which will not have their profits materially affected by an extension of burdens in other directions, will heartily welcome the relief. This applies to a considerable number of workers in the gas industry. The increase in the relief, too, to earned incomes from one-tenth to one-sixth, with the maximum deduction raised from £200 to £250, is satisfactory; and the treatment of investment income as earned income of taxpayers 65 years old or more (with incomes not exceeding £500) is also a step in the right direction, as many relatively small recipients of investment income find the standard tax at such rates as are now ruling a burden and deprivation which does not conduce to the happiness of their old age. Those fortunate ones who will get relief in respect of super-tax are also thankful. The new scale of death duties will bring an additional revenue to the exchequer. But, taking together the relief to super-tax payers and the increase in the death duties, the transfer of tax from income to capital is, of course, unsound in principle. The return of the McKenna duties has given satisfaction in those industries which will gain from the protection; but there has been a big outcry against the increase of duty on silk and artificial silk. The unhappiness that has been created by this in the trade, and especially among the fair sex, has led to the expectation that there will be modification in this regard. Imperial preference is welcomed by most people other than the Labour Party. Views as to the restoration at the present time of the gold standard are mixed in view of the serious industrial and trade depression and the ruling heavy taxation. There are those who believe this will impose a further strain upon industry; but the apprehensions of many should have been allayed by the debate in the House last Monday.

But it is the big extension of the Health Insurance Scheme on a contributory basis, with provision for pensions for the widows of insured men, and allowances for children up to the age of 14, which has raised the greatest controversy. From Jan. 6, 1928, all contributors, male or female, over 65 years of age will receive 10s. per week irrespective of means test or inquisitions. For this scheme, in addition to the present health insurance contributions, the employer has to pay an additional 4d. a week for every man, and the man an equal sum; while the respective contributions for every woman will be 2d. In these times of depression and heavy taxation, this is a new burden of a magnitude which will be especially onerous to those industries and businesses the nature of the operations of which calls for a considerable number of workers; and it is these very industries which require their burdens lightened in these days of rampant unemployment. With the principle and objects of this extension of universal insurance among workers, no one will disagree; but a more inopportune time for its launching could not have been found. The gas industry has been forced into increasing the price of gas owing to the bad conditions ruling in the markets for their secondary products, and certainly will not be pleased—more especially bearing in mind what is already done for the workers—at having to face just now an additional obligation in this direction. As Sir Robert Horne has pointed out, industry at the moment has already to find 36 million pounds for unemployment insurance and 26 millions for health insurance; and the new imposition will mean anything between an additional 14 and 20 millions. The Chancellor has some hazy notion that there will be a large adjustment by the weeding-out of the undeserving from the deserving in the case of unemployment, and so lightening the payments in that respect. The Government are determined to deprive of the "dole" those who are better satisfied with it than with work. But that is, in the present state of industry and unemployment, a vague form of partial compensation to have in view. There is unquestionably a hardening of opinion in the direction of insisting that the Chancellor shall find some method of relieving the burden of contributions by an amelioration of conditions in some other direction. It is understood that the matter is being very seriously explored by the Treasury in view of the strength of the representations that have been made and the probable opposition—not perhaps for all time, but now. It is understood that the influential Industrial Group in Parliament will bring their weight to bear upon the matter. The Labour Party, too, do not like the contributory part of the scheme—so far as the workers go—and they consider the benefits proposed are not proportionate to the extra contributions and the increased cost.

The Budget, however, is essentially one which will give satisfaction or otherwise just as it affects personal interests. The country has been called upon to bear unprecedented burdens during the last decade. It is suffering from them now; and relief to the fullest possible measure, without new burdens, is necessary to supplement the expenditure of effort to bring about the prosperity which alone can give us industrial peace and general contentment.

Gasholder Tank Troubles in Mining Areas.

From time to time gas engineers hear and read of the difficulties that are experienced by their colleagues who are in charge of gas works and distribution systems in districts undermined by colliery workings. As they read or hear, they sympathize, and then perhaps forget all about the matter until, for example, a Commission sit to inquire into, and report upon, the effects on property, including gas plant, in areas honeycombed by the removal of the subterranean wealth. But those engineers who are immune from troubles due to this cause will unstintedly congratulate themselves upon the fact after they have read the paper on "Experiences with Gasholder Tanks in a Mining Area" which Mr. Charles Dru Drury read before the North of England Gas Managers' Association at their meeting last Friday. The contribution should be presented to the members of the Commission on Subsidences in Mining Areas. They would see how jeopardized is the property of public utility concerns so situated, and therefore the supply to the public of a commodity which has become an essential in almost every household and industry. The winning of coal must go on even though on the surface there are buildings and plant. Something, however, should certainly be done to give more protection than is the case at the present time; and if and when such workings are going to be carried under heavy surface plant, the opportunity should be afforded to take any protective measures that may commend themselves. But reading Mr. Drury's paper, we see that, in several of the cases described of serious difficulty with holder tanks, the first intimation that the colliery workings were causing dangerous conditions which would threaten the plant was supplied by houses and other premises in the neighbourhood developing cracks. A gasholder tank, with its dead weight of structural material and water, is not a light thing; and that its soundness should be maintained is important on account not only of its initial cost, but also of the heavy expenditure entailed in rectifying faults developed by outside influences. The detection of those faults is sometimes difficult and money and time absorbing, as is the determination of the full remedial measures. Moreover, while thrown out of service, to the extent of the storage involved, the capacity of the undertaking is weakened for satisfactorily serving the public.

We do not think any engineer would wittingly construct a gasholder and tank upon a site which he believed would before long be undermined by colliery workings. The point is noticed in Mr. Drury's paper that, in most of the instances of tank trouble which he mentions, the holder tanks had continued true and stable over a good course of years before there was any unusual sign of trouble, which indicates that, when their sites were originally chosen, there was no anticipation of these events—not even an idea as to their distant possibility. A trouble is that even the best engineering knowledge and skill cannot construct a gasholder tank of which it could be confidently asserted that it would be free from injury as the result of the assaults of colliery operations. Mr. Drury's paper shows that in his professional practice he has had to deal with tanks that had dropped out of level, and developed fractures to such a degree that the water flowed away at an alarming rate, and rendered the holders useless for service, until remedial measures—sometimes of a vast order, and demanding skill, perseverance, and patience in exploration and application—set matters right, only to be followed by long watchfulness to ascertain whether the success could be relied upon as being more or less permanent. Without reward one may search the paper from beginning to end for some light as to the type of tank which experience has declared to be the best capable of resistance to the dire effects of such subsidences; but there is the cold declaration that "none is wholly proof against the effects of subsidence, should it occur," and "even the tankless holder in like circumstances would not be immune from trouble." There is one thing certain, that if serious trouble does develop through subsidence by colliery workings, an inexperienced engineer in such matters should immediately call in an experienced one; for as the paper is read, and the different examples of tank trouble through subsidence are studied from first discovery to the remedial operations and their results, it is plain that the exploration that has to be made, the decisions that have to be arrived at, the steps that have to be taken to secure soundness and stability are not of the ordinary work of a gas engineer, and in such cases experience and resourcefulness count for much. There are hardly two cases in which the structural defects arising from subterranean disturbances were the same, and where the corrective operations were of like order. It is manifest that each case has to be considered and dealt with independently—sometimes drastically, but always with a skill and ability which allow nothing to escape which may again menace the soundness of the fabric of the tank. It may not always be possible, as in the last example quoted by Mr. Drury, to complete the elimination of the defects or the causes of the defects at the first attempt; and this is a greater reason why, in carrying out such operations, an engineer with experience of underground disturbances and tank disablements should be called in either to take the whole matter in hand, or to act in an advisory and supervisory capacity. In the end, by this course, there is little question that, in most cases, money and time will be saved, and the holder restored to normal working at the earliest possible date.

In the paper—high in quality and engineering value—Mr. Drury gives an account of how the misfortunes arose to the holder tanks which are used as examples, the nature of the explorations made to ascertain the causes, and details as to the expedients to which there had to be resort to realize success. The effectiveness of the work in each case is shown by continued tank tightness over the period which has elapsed since the work was carried out. In other words, time attests the efficacy of what was done. Descriptive details of the kind do not give much scope for comment; they are for reading, study, and guidance. All that is required is cordially to thank Mr. Drury for a paper that is novel and even fascinating; for among the things of which an engineer likes to hear is a tough job environed with difficulties, which have been made to succumb to the treatment prescribed, after careful diagnosis, by a fellow practitioner.

Smokeless Heating and Coal Conservation.

The District Conference of the "B.C.G.A." which was held at Chester last week was one of those delightful occasions which—through the surroundings, the generous hospitality, and matter for discussion of a high standard—are long retained in memory. To the Chairman of the Gas Company (Sir John M. Frost), his fellow-Directors, and the Secretary and General Manager (Mr. F. A. Pye), hearty acknowledgments were due and were given for putting upon the day's arrangements just those touches of welcome, entertainment, and direction which make for maximum success. These district conferences are something more than meetings at which subjects of interest to those engaged in the industry are discussed. The proceedings are intended to reach the outer world, and to interest in gas affairs the public in a large surrounding area; and this aim is always accomplished. On this occasion, the dominant subject under consideration was the position occupied by the gas industry in relation to coal conservation, the reduction of smoke pollution, and labour saving; and that position—taking those items separately or combined—was shown to be pre-eminent among the heating agents. Electricity is offered at 1d. per unit for heating purposes; sometimes a higher average price is, through the two-part tariff system, secreted in a lump-sum payment. But the penny is a reflection of the difficulty in meeting competition; and the industry also callously ignores the waste of our chief national asset in the production of electrical energy for heating.

To the consumer and to the nation, the use of electricity for domestic heating is an uneconomy of no small order. That is a point electrical men attempt to hide; and the Government appear to be too busy with other matters to give attention to it. Yet it is an outstanding national matter in view of the nearly 40 million tons of coal consumed to-day in the households of the country, to say nothing of the many more millions used in industry, and in view, too, of the insanitary conditions of the atmosphere and the appalling waste of health, money, property, and human energy which is brought about by the burning of

raw coal. Taking together the domestic and industrial requirements for heat in the country, they far transcend the demand for power; and yet the Government proceed as though power and nothing else is the necessity to which thought should be given. With power is combined the question of heat for its production; and therefore fundamental to it all is the most economical method of producing that heat in the national interests—and the national interests are those of the country's industries. It is well known that an inclination in Government policy is to finance electrical development without consideration of those radical questions to which attention is drawn here. Sir John Frost made this point, in other words, when he said that the gas industry in this country had developed to the highest efficiency without State aid, and so had all the other foundation industries of the country. The electrical industry does not seem at all abashed over the fact, or in any way averse to accepting State aid to secure development at other people's expense, although the country is overburdened with taxation to-day. The injustice to other industries of preferential treatment in this respect does not in the slightest degree disturb its conscience; and yet it can be proved beyond contradiction that the utilization of coal for generating electrical energy for heating purposes is a distinctly uneconomic proceeding. The speech of Sir John Frost, and the paper by Mr. Owen Evans on "National Economy in the Use of Coal," brought these matters definitely to notice and to narrow compass; and Dr. Harold Hartley showed how gas has ameliorated the conditions of labour in the home and assisted in the purification of the atmosphere, and this by indisputably the most economical smokeless agent extant.

In one of the discussions, a novel suggestion was made by Mr. J. H. Crowther. It was that municipalities, instead of looking to their gas undertakings to contribute something in aid of the rates, should make a contribution to gas undertakings to enable them to sell gas at a nominal price. What was lost in one way would, Mr. Crowther said, be gained in another—in the health of the community. The idea of helping to make gas cheap as being part of the highest service local authorities can render to their communities has probably never occurred to any of our urban governing bodies. We should like to see the point discussed by them from the standpoint of local advantage, or disadvantage—if any can be found. The question of whether or not legislative authority would have to be obtained for such an innovation could be left until the question of advantage or otherwise had been determined. Our view is that any disadvantage that might be advanced would be easily overwhelmed by the advantages. However, the proceedings at the Chester District Conference are studded throughout with good points worthy of being remembered, and for production and use in our daily work as occasion requires.

Doctors, Coroners, and Carbon Monoxide.

IT is a curious thing how some doctors and coroners—fortunately not many—appear prepared nowadays always to attribute to carbon monoxide poisoning the death of a person when it occurs in a room in which gas is being used. At one time in the case of bathrooms—unventilated, and in which geysers had been fixed without a flue-pipe (to which practice the gas industry is strongly opposed)—deaths that occurred on rare occasions were ascribed to suffocation by carbon dioxide. There was more truth in that than in the carbon monoxide theory; and some of the cases asserted to have been due to suffocation may have been attributable in part to organic disorders in the victim. We do not deny that, when a geyser is first lighted and the flames come in contact with cold surfaces, carbon monoxide may be generated. But this is only temporary; and if the geyser has a vent-pipe to the open air, there is no more liability to trouble in a bathroom than if a coal fire were used. As a matter of fact, the average carbon monoxide content of the waste products passing up a chimney from a coal fire will be a larger percentage than that flowing away temporarily by the vent-pipe from a geyser. It seems to us that some of our medical practitioners and coroners require to have their attention expressly brought to the elementary facts regarding the combustion of gases and the waste products from that combustion in different circumstances.

It has been noticed on several occasions that death has been attributed to carbon monoxide poisoning when the published facts do not by any means support the statement. There was the case only a few weeks ago of a house parlourmaid at Chelsea, who was found dead in a bath. A geyser was used in the bathroom; and it was stated by a doctor that death was due to carbon monoxide poisoning. When the young woman was found in the bath, the geyser was still burning. Now that geyser had probably been in use for some time before the sad event; and we have seen no evidence to the effect that there had previously been any trouble with, or complaint regarding, it, nor had anybody suffered any harmful consequences through its use. Indeed, the geyser has since been carefully examined by an inspector of the Gas Company; and it was found to be in good working condition. In fact, there was nothing wrong with it. That being so, where could the carbon monoxide have come from to which the doctor attributed death? The Coroner (Mr. H. R. Oswald) confessed that the case was a puzzling one; and he stated that he has a geyser in his own house, but always opens the window of the bathroom some time before having a bath. That is quite a sensible thing to do. Bathrooms, whether or not there is a geyser in them, should be adequately ventilated the same as other rooms; but unfortunately there is usually very little attention to that condition. The geyser naturally requires a supply of air; but as long as the flames are burning properly, the necessary quantity of air for that purpose and for human existence will be satisfactory. The fact that the heated products are flowing up a vent-tube will induce better ventilation than would otherwise be the case in a closed bathroom without the geyser and without any means of ventilation.

It is true that, in the case alluded to, a verdict of "Accidental Death" was returned; but we are rather afraid that the Coroner is not altogether satisfied as to the absence of carbon monoxide from the bathroom. Among other things, he said the case reminded him of one he investigated "some time ago," when a man was found dead in front of a lighted gas-fire. That is interesting from the fact that, although there are to-day millions of gas-heated appliances in use in this country, it is "some time ago" since that case occurred. Furthermore, the death of a man sitting before a gas-fire or any other fire, is not evidence that the fire was the cause. Bearing upon the observation by the Coroner, he may be interested in the experiments of Dr. Leonard Hill, F.R.S., on the question of the safety of gas-fires in regard to carbon monoxide. The results of the researches were published in the "JOURNAL" for April 8 (p. 110).

Gas Workers' Wages.

The Labour Correspondent of "The Times," who is probably in close touch with the Unions identified with the gas industry, reports that negotiations on the wage proposals have been resumed in the gas industry. The annual meeting of the Joint Industrial Council for the industry provided an opportunity for the employers' and the workmen's representatives to come together; and the danger of the disbandment of the Council has been averted for the present by the resumption of discussions on the wage claims. But the fear of unfortunate consequences has not yet been removed. Before the meeting, the two sides of the Council met separately—Mr. D. Milne Watson presiding over the employers' section, and Mr. Will Thorne, M.P., over the trade union section. The Council met later; and the annual report and the financial statement were adopted. Before taking other business, the Council considered the wage proposals. Agreement was not found possible; and after a lengthy sitting the meeting was adjourned for six weeks.

Coke Sales by Analysis.

A development which will be noted by those who are preparing papers for the coke competition (see "JOURNAL" for Feb. 18) is the sale of coke by analysis. The idea is more or less in the initial stages; but it is in practice in the West Cumberland and one or two other areas in connection with metallurgical coke. It seems, however, that the scheme is

being pushed by buyers rather than by the producers; and that is not surprising. The development has been the subject of an editorial article in "The Engineer." Explaining it, our contemporary says: "The new scheme is that coke shall be sold on a 10 p.ct. ash basis, and that, if the ash should be 11 p.ct., a reduction of (let us say) 6d. per ton as being not far from the mark should be made in the price. Conversely, if the ash should turn out to be 8 p.ct., the buyer would have to pay a further 1s. per ton. What the arrangements are, if any, as regards water, sulphur, or other components of the coke, we do not know. A difference of 1 p.ct. of ash in the coke is thus seen to be equivalent to £25 on 1000 tons—a matter which in these strenuous times may be considered of importance." One reason for opposition to the plan is given by the producers' association in an important district. It is the difficulty that is to be apprehended in respect of correct sampling. Ash in coke is not evenly distributed—in fact, a large piece may show wide variations of ash content in different parts. This indicates that sampling would have to be carried out on a considerable quantity of material and by a trained sampler, if disputes are to be avoided. Our contemporary, assuming absence of disagreement over the sampling, says the new scheme appears to be a desirable development.

Tar and Bitumen.

That very active work is in progress in opposition to the use of tar dressing on roads in proximity to fishing waters, with strong and influential advocacy of bitumen, is seen from a report which is reviewed in later columns. The matter is being attacked not only from a biological standpoint but from that of the chemical purity of rivers. The exploration is to be largely developed in the scientific direction.

The Factory Bill.

In our "Electricity Supply Memoranda" reference is made to the Factory Bill, and to matters associated with it that are of importance to the gas industry. Although the provisions of the Bill are not yet available for examination, sufficient is known regarding it to justify the remark that the representatives of the industry will have to keep very careful watch over the measure to see that its interests are not detrimentally affected. Two or three weeks ago, the Government were of opinion that the Bill might be passed through Parliament this session. But the political situation and outlook undergoes rapid transformation these days; and it is now stated that, though the Bill will probably be formally introduced this session, it is not likely that progress will be made with it before the session of 1926.

Aldershot and the Capital Issues Act, 1920.

More than ordinary interest attaches to the Aldershot Gas, Water, and District Lighting Company's application to the Board of Trade for a Special Order. It intends to confer further capital and borrowing powers, and contains a proposal which has relation to the doubts that have recently existed as to whether unexercised authority obtained under the Public Utility Companies (Capital Issues) Act, 1920, can be utilized after the expiration of the Act on the 20th inst. The Act gave the power, with the assent of the Board of Trade, to issue debenture stock or borrow to the extent of one-half of the share capital for the time being issued and paid up. In the "Journal" for April 8 (p. 107), reference was made to Counsel's opinion obtained by the National Gas Council, as to whether unexercised powers would be valid after the 20th inst.; and it will be remembered that the opinion was distinctly opposed to the hypothesis that they could be. The Aldershot Company have, as the Chairman (Mr. R. W. Edwards) pointed out in a speech to the shareholders last Thursday, accepted the view of Counsel, and so are going to ask the Board of Trade, by Special Order, to make a one-half proportion the permanent relation between the Company's borrowing powers and share capital. So far as memory serves, Mr. Edwards is right in saying that he believes the Aldershot Company is the first to adopt Special Order procedure for this particular purpose. There is no reason why the one-half proportion should not be made permanent in view of its advantage, and the fact that there is precedent for it in Acts of Parliament. If the Order succeeds in this respect, it will constitute a precedent for obtaining an extension of loan capital powers without the delay and expense entailed in seeking authority direct from Parliament.

A Promise for Wembley.

Summer months during which there is a plethora of rain rob us of much opportunity and pleasure. The Duke of York (who this year is President of the British Empire Exhibition) is of opinion that the weather last year robbed the exhibition of many millions of visitors. At a luncheon the other day he expressed the hope that those millions and many more would be attracted to Wembley this year. He believes that, if the weather is not again unkind, the millions desired will pass through the turnstiles. He promises that the Exhibition will be as complete and impressive a picture of our great heritage of Empire as was seen in 1924; but it will be a new picture—a picture seen from a different angle, a picture showing fresh aspects of our Imperial life. The exhibition will follow faithfully those modern methods of education which insist that, before all things, a lesson must be bright and interesting. As His Royal Highness says, "it is incumbent on all of us to do our utmost to make the 1925 season a brilliant success."

Coke and Power Alcohol.

The "Petroleum Times" reviews an article by Mr. Herbert Langwell, which has appeared in the "Industrial Chemist," and in which is discussed the question of the production of power alcohol. This gentleman takes the line (as has previously been done) that material suitable for food cannot be economically utilized for power purposes. In view of this, the production of synthetic alcohol requires consideration. He refers to two processes which have been investigated; but it does not appear that with them commercial success has yet been achieved. These systems may be described as the "carbide-alcohol" process and the "water gas-methyl alcohol process." In both coke would be used—if successful; and in that event the gas industry would welcome them. The first consists in converting coke and limestone into carbide of calcium for acetylene production. The acetylene may be converted into alcohol *via* ethylene and ethyl sulphuric acid, or *via* acetaldehyde. The conversion of acetylene into ethylene, although a simple laboratory process, is not easy on a large scale; but the technical difficulties in converting acetylene into acetaldehyde appear to have been overcome by a Swiss firm, who, however, have not yet made the process commercially successful. The water gas-methyl alcohol process is quite a modern one; but this also has not yet reached a commercial stage. It depends upon a catalytic reaction by which carbon monoxide and hydrogen are made to combine to form methyl alcohol. The large employment of water gas for this purpose would involve a considerable consumption of coke. However, Mr. Langwell thinks that the most promising source of alcohol is cellulose. The "Petroleum Times" (with an eye upon the interests of the industry it serves) says that, in discussing the production of alcohol *via* ethylene and ethyl sulphuric acid, Mr. Langwell is either not aware, or has overlooked the fact, that gases of the ethylene series are being produced in very large quantities in petroleum cracking processes, providing a practically ready-made material for the production of ethyl and other alcohols.

Iron and Steel Industry.

The number of furnaces in blast is always a reliable index as to the conditions ruling in the iron and steel industry, and the prevailing conditions are anything but good. At the end of March there were 169 furnaces in blast; in the December quarter, 171; in the September quarter, 176; in the June quarter, 196; and at the end of March last year, 208. A difference of 39 is a big one on such a number in twelve months; and the figures show that the fall has been of a gradual order.

Gas Companies and Electricity Orders.

The Statutory Gas Companies (Electricity Supply Powers) Bill went through Committee yesterday morning. We congratulate the promoters. It will be a useful supplement to the enactments applying to statutory gas companies, as it will

(when it receives the Royal Assent) authorize them to apply for Special Orders under the Electricity (Supply) Acts, 1882 to 1922, and to use their funds in the promotion of such applications. It also invests the Electricity Commissioners with authority to empower—subject, after consultation with the Board of Trade, to such limitations and provisions (including the keeping of separate accounts) as they see fit to impose or insert—any statutory company to apply their funds to, and to raise capital or borrow money from time to time for, electricity purposes.

NATIONAL GAS COUNCIL.

District Executive Board Meeting.

SOUTH-WESTERN AREA.

The Annual Meeting was held at the offices of the Exeter Gas Light and Coke Company on April 30—Mr. G. Hardy Harris (Exeter) in the chair.

The minutes of the last annual meeting, dated May 15, 1924, were read and confirmed.

The Chairman read, and moved the adoption of, the report of the Management Committee for the year ended March 31, 1925. Mr. P. S. Hoyte seconded, and the report was adopted.

The list of elected members for the District was received.

Mr. P. S. Hoyte proposed, and Mr. S. J. Ingram seconded, that Mr. G. Hardy Harris be re-elected Chairman of the District Executive Board for the ensuing year. The resolution was carried unanimously. On the motion of Mr. G. Hardy Harris, seconded by Mr. W. P. Tervet, Mr. P. S. Hoyte (Plymouth) was unanimously re-elected Vice-Chairman.

The following twelve members were elected on the Management Committee: Messrs. J. Armstrong (Ilfracombe), R. Bruford (Taunton), J. H. Cornish (Bridgwater), C. G. Dawson (Torquay and Paignton), W. E. Dean (Exmouth), S. E. Hallwell (Bristol), S. J. Ingram (Truro), J. E. Norman (Weston-super-Mare), W. P. Tervet (Plymouth Corporation), W. N. Westlake (Exeter), J. W. Whimster (Bath), and T. H. Woodcock (Stroud).

Mr. G. Hardy Harris proposed, and Mr. T. H. Woodcock seconded, that Mr. S. J. Ingram (Truro), who retires in rotation, and is eligible for re-election, be re-elected one of the representatives on the Central Executive Board. This was carried unanimously.

On the motion of the Chairman, seconded by Mr. C. G. Dawson, it was unanimously resolved that Mr. E. H. Dart be re-elected Hon. Secretary for the ensuing year.

"House Heating."—This book, written by Dr. Margaret Fishenden, and published by H. F. & G. Witherby (price 25s. net), is a general discussion on the relative merits of coal, coke, gas, electricity, &c., as alternative means of providing for domestic heating, cooking, and hot water requirements.

"Metalworkers' Practical Calculator."—This book, which has just been published by Sir Isaac Pitman and Sons, Ltd. (price 2s. net), is intended primarily for the man in the workshop and the private student. For this reason the examples have been stated as simply as possible, even to the extent of ignoring convention. The working-out of the examples has been shown in detail, for instructional purposes. The book has been written by Mr. J. Matheson, author of "Intelligence Training" and "Practical Applied Grammar."

National Benzole Company's New Installation.—An illustrated description appears in "The Petroleum Times" of the new plant in Liverpool of the National Benzole Company, Ltd. This installation, at Dingle Point, has been designed for receiving ocean tankers and storing and delivering both benzole and petrol; and it has a storage capacity of approximately 12,000 tons. The management estimate that the new depôt will enable the handling of 200,000 gallons of "National" benzole mixture per month by road. The storage facilities have been constructed by Messrs. Newton, Chambers, & Co., Ltd., of Sheffield, and consist of three tanks, each of 3000 tons capacity, and two tanks of 1500 tons each.

Southern Association Visit to Bournemouth.—Arrangements have now been completed for the visit to Bournemouth on June 5 of the Southern Association of Gas Engineers and Managers. Members will assemble at 10 a.m., in the Square, Bournemouth, where motor coaches will be in attendance to convey them to Pitwines and Poole Gas-Works. At 12.30 the party will return to the Branksome Towers Hotel, where they will be the guests at luncheon of the Chairman and Directors of the Bournemouth Gas and Water Company. After luncheon the visitors will leave by motor coach, *via* Kingston, for Swanage, where tea will be provided at the Grosvenor Hotel. The return journey will be made *via* Rempstone and Corfe Castle, arriving at Bournemouth Square at 6 p.m.

PERSONAL.

On leaving to take up the post of Distribution Superintendent to the Macclesfield Corporation gas undertaking, Mr. F. C. RANDALL, District Inspector of the Exeter Gas Company, was presented by his colleagues with a gold albert, and by the fittings staff with an attaché case.

Upon relinquishing his position as Manager to the Launceston Gas Company, in order to take up an appointment in Guernsey, Mr. R. G. LUXON was presented by the employees with a silver cigarette case. He is succeeded in the managership by Mr. J. W. GIBSON, of Swanage.

ELECTRICITY SUPPLY MEMORANDA.

The Investigation.

It is understood that probably another fortnight will have to elapse before Lord Weir's Committee will be able to present to the Minister of Transport their report on the development of electricity supply in this country. We shall be rather curious to see the issue of this, because, knowing the thoroughness of Lord Weir in all matters appertaining to engineering, as well as his interest in the question of the conservation of coal and the co-ordination of the utilization of our fuel supplies, we are hoping that the report will not be of the one-sided and barren character of other reports on the same subject—through electrical obsession and a preponderance of electrical opinion on the Committees who have previously dealt with the matter. Through this there has been no genuine exploration beyond the electrical boundaries to ascertain whether the national interests can best be served by breaking through them, and opening up fresh technical procedure. It was thought at one time the Government would be able this session to produce a scheme to increase electricity availability; but it is no use half doing a piece of work of this character. Lord Weir's Committee have found that the subject was so extensive that more time than was anticipated was necessary for investigation, consideration, deduction, and final presentment of views and recommendations. After this there will have to be a large amount of work at the Ministry of Transport before the proposals can be matured and put into form for submission to Parliament. At the recent dinner of the Institution of Electrical Engineers, Col. W. Ashley emphatically stated that the Ministry of Transport would not lay any scheme before the Government until it has been thoroughly examined, and the propositions have received the most ample consideration. It would appear from this that light has already been creeping into hitherto dark places from which emanated, with fine agility, fanciful predictions as to what the Government were prepared to do. If properly sized, it is a big complex problem, and no part of it should be left unexplored. Then something with completeness and finish should result, and something which takes a broad and long view of national interests. Fuel, power, and heat all have part in the problem, and so have the economic interests of the nation. The question now is, Have Lord Weir's Committee risen to their opportunities?

Preferential Legislation.

If the Factory Bill which the Government propose to introduce contains provisions which savour of grandmotherly interference with industry or impose any unnecessary burdens upon it, there will be such an outcry that even the Government will be made to feel that influential people in the country will not tolerate political tyranny even from their own party. There have been leakages as to the contents of the Factory Bill which is being trimmed and shaped for introduction to Parliament, and prominent manufacturers are already looking upon the measure with suspicion. So much so is this the case that the National Union of Manufacturers have already had an interview with the Home Secretary, at which representations were made as to ample time being allowed for the consideration of the provisions of the Bill, and regarding the need for avoiding further burdens at the present time upon industry in its depressed state. At the interview, strong exception was taken to various features in the Bill introduced by the late Labour-Socialist Government—more especially in respect of limitation of the hours of work and the powers of the Home Secretary and inspectors concerning cubical capacity, heating, lighting, ventilation, cleaning, &c. There is good ground for that—in regard to lighting especially. Every industry and every process requires different illumination treatment; and it would be a disastrous thing if lighting requirements were left to a dictatorial inspector, who has not the technical knowledge of illumination need for different classes of work, &c. We should not like it to be thought that our opinion is that all factory inspectors are dictatorial; but there is inclination to the view that lighting science and practical requirements, with one exception, are not within their compass. The exception is adequate general lighting, particularly at dangerous points, and this any man should be competent to

judge. The Home Secretary asserts that it is his earnest desire that the measure should be beneficial to both employer and employed, and not prove a burden to the manufacturing community of the country. If that is so, then perhaps he will see to it that unnecessary expenditure in regard to lighting is not imposed upon the factory owner by any insistence on the conversion from gas to electric lighting. We frankly admit that the gas lighting of many factories sadly wants improving; and modern economical and highly efficient gas-lighting methods offer the scope for it, without the expense of changing from one system to another. In every possible way, those who are in a position to pull political strings for the electrical industry are doing so. There is the Offices Regulation Bill, which proposes to enact that every office must be adequately ventilated and lighted both by day and night. Similar provisions appear in the Factories Bill introduced by the Home Office during the reign of the last Government. It has been found that it was the intention of the Home Office to become invested with the power to interfere with the liberty of the subject by ordering the owner and occupier of any office to substitute electricity or some other method of heating or lighting, in lieu of gas, where they thought fit. Steps, we believe, have been taken to frustrate this absurd design, the very suggestion of which shows positively that ill advice sometimes rules in high quarters simply because the necessary knowledge is not there available to arrive at a proper determination. However, so far as the Factory Bill goes, there will now be plenty of opportunity to discuss the provisions, as, though a week or two ago it was hoped that the Bill would receive consideration from Parliament this session, it is now found that the session is already overweighted with work, and therefore, though the Bill may be formally introduced in a few weeks, it is not likely it will be seriously handled before the session of 1926.

"E.D.A." and Wembley—Last Year.

The annual meeting and luncheon of the Electrical Development Association have been held. The after-luncheon speeches contained many nice things as to the work of the Association, and an appeal for greater co-operation. One of the speakers stated that during the past five years work has been proceeding to convert the industry, and now the next step is to get the members of the Association to convert the public, with the aid of the Press. That is a very limited aspect to take of the past work of the Association; and as to the future our interest is aroused in the conversion scheme, as it has, of course, something to do with the current utilization of gas. There has been strenuous work during the past few years to convert the public, with enormous difficulties interposed which are inseparable from electricity supply, and which the electricity industry feels more and more. Wembley, it is stated, was only a beginning; and funds are now being raised to educate the public in modern electrical methods. Some of the electrical papers are disappointed with the speeches made at the luncheon. With members of the daily Press there, they are of opinion that a grand opportunity was lost. However, about Wembley last year, it is stated that support was received from 152 municipal undertakings, 89 companies, 19 power companies, and others; and the funds collected amounted to £24,440. Assistance was also received from the "B.E.A.M.A.," the "E.L.M.A.," the "C.M.A.," and the "E.C.A." by way of loans of material and labour, having a cash value of probably £2000. An expenditure of £5039 was also incurred on advertising—the total outlay on the effort being £33,373. It is estimated that a million persons passed through the exhibit, 400,000 conversed with the staff, and 10,000 inquiries were dealt with. The exhibition was open about 156 days, so that the 400,000 conversations equal about 2600 a day and, reckoning ten hours a day, an average of 260 conversations an hour. That is smart work; but brevity is the soul of wit. There are several humorous points about the application of electricity to domestic purposes. Had the public been told of them at Wembley, we should have seen more merriment and activity round about the "Electricity in Service" display last year.

Other Work.

The report on the year's work states that the membership at Dec. 31 last included: 101 municipal supply undertakings, 13 London companies, 11 power companies, and 62 provincial companies; manufacturers 243, contractors 830, and wholesalers 66—total 1326. The supply membership represented 75 p.ct. of the total output of the country. The subscription revenue was derived as to 55 p.ct. from supply undertakings, 40·5 p.ct. from manufacturers, and 4·5 p.ct. from contractors and wholesalers—the total being £10,654. During the year, Sub-Committees were engaged upon the study of domestic electrification, standardization, reform in tariffs, local exhibitions, agriculture, wiring rules, &c. Press advertising was carried on, especially in connection with the British Empire Exhibition and late shop-lighting. A large amount of publicity was also obtained for the electrical industry through the editorial columns of the Press. Over three million items of publicity matter were purchased from the Association, besides which very large quantities of such matter were distributed by the Association at the British Empire Exhibition. Several kinema films were added to the stock, bringing the total up to ten films, which were in constant demand. Lectures were also delivered by the staff and by helpers, and the lantern slides and lecture notes were in continuous demand. Short talks on electrical subjects were given to students of both sexes in schools. Salesmanship conferences were held, for the fourth season, leading to increased enthusiasm and a demand for reprints of papers. Assistance was given to the Women's Electrical Association and other bodies, and arrangements were made for a very effective display of "Modern Lighting Service" by the "E.L.M.A." Joint Lighting Service Bureau at the "I.M.E.A." convention. During the International Advertising Convention, papers were read in the Public Utility Section by members of the Association; and in connection with the Coal Smoke Abatement Society's Exhibition an "All-Electric House" exhibit was organized, which was visited by 41,000 persons. Numerous reports on matters relating to the commercial development of electricity supply were circulated to all the electrical undertakings in the country. Congratulations to the Association on the expansion of its activities.

Per Capita Data.

Sir Philip Nash, speaking at the annual meeting of the Metropolitan-Vickers Electrical Company, Ltd., made comparisons of how this country stands in respect of the output of electricity per head of the population. He finds that we are in a relatively sad position, if Italy and Germany are excepted. The figures are as follows:

	KW.H.		KW.H.
Great Britain	133	Germany	120
U.S.A.	450	Italy	103
Switzerland	682	Norway	1850
Canada	765	Belgium	230
Sweden	475		

The figures are arrived at by taking the total production of electrical energy in each country, and dividing it by the population to show the output per head. The figures are for 1922, so that the last two years may have made a considerable difference to the position of this country compared with others. As a matter of fact, although complete statistics for all the countries are not yet available for subsequent years, it is known that in 1923 the British figure had risen to 155, that of Italy to 129, U.S.A. to 528, Switzerland to 805, and Canada to 910. The effect of water power generated current is seen in the data. The statistics Sir Philip regards as showing very clearly the relatively backward condition of this country electrically. A further interesting comparison is that the capital invested per head of population in U.S.A. in 1923 was $42.5, or (say) £9 5s. In Canada, $77, or (say) £17; in Switzerland, £10 5s.; in Great Britain, approximately £4 15s. But such figures are not really a reliable index, in view of the fact that all the costs involved in capital expenditure vary considerably in different countries. In connection with this subject, it is interesting to observe that a great deal of electrical propaganda is under way; and, among the recent published statements, we find that it is estimated that out of 1,250,000 domestic house consumers in the United Kingdom only about 300,000 use electrical energy for purposes other than lighting.

Exhaust Gas Poisoning.

In view of the number of fatalities from carbon monoxide given off by the exhausts of motor engines, the engineers of the National Employers' Mutual General Insurance Association, Ltd. (Accident Prevention Department), Nos. 1-2, George Street, Mansion House, London, E.C. 4, have investigated this hazard. The average six-cylinder engine produces from 4 to 12 c.ft. per minute; and investigations have proved that 0·05 p.ct. of carbon monoxide in the atmosphere constitutes a danger. Working in a garage 20 ft. by 20 ft. by 10 ft., an engine may, in less than two minutes, discharge carbon monoxide in excess of this dangerous limit. An unconscious state is so quickly reached that a person in the garage rarely has sufficient time-warning to get into the fresh air. If the engine must be started-up in the garage, it is advisable to back the car out about 5 ft., and see that the rear of the vehicle is beyond the doors of the garage, and the engine emitting the fumes into the open. If for any reason the car cannot be moved, it has been found practicable to clamp a length of hose pipe to the exhaust, thus leading the gas away from the garage. The practice of running the engine in the garage must generally be condemned as an unnecessary hazard.

"The Carburettor Handbook."—Of all the components that constitute the modern internal combustion engine, and particularly the modern car engine, the carburettor is the one which can have the widest range of influence on its performance. In "The Carburettor Handbook" (published by Sir Isaac Pitman & Sons, Ltd., price 10s. 6d. net), the author, Mr. E. W. Knott, explains in non-technical language the principles and theories of carburation as they are understood to-day, and the way in which these theories are claimed to be carried into practice by the inventors and manufacturers of modern carburettors.

BENZOLE RESEARCH.

Reports of the Joint Benzole Research Committee.

As our readers are aware, the National Benzole Association and the University of Leeds have a Joint Benzole Research Committee, whose work is carried on under the supervision of Prof. J. W. Cobb in the laboratories of the University or in industrial establishments, wherever it becomes necessary. At the meeting of the National Benzole Association in March (as reported in the "JOURNAL" for March 25, p. 751), the President, Mr. D. Milne Watson, referred to the interest contained in the last issued report of the Research Committee. When the Committee first started its operations, Mr. E. C. Williams, M.Sc., was the Research Chemist until he was elected to the newly-established Ramsay Memorial Chair of Chemical Engineering in the University of London; and he was largely responsible for the researches included in the First Report, which was presented to the National Benzole Association on Feb. 27, 1924. In order that readers of the "JOURNAL" may have before them a review of the work of the Committee so far done, it is proposed to-day to deal with the First Report, and in a subsequent issue the Second Report, which is the one to which the President referred at the last meeting of the Association.

FIRST REPORT.

After consideration of the commercial and practical possibilities of various substances which exhibit the phenomenon of adsorption—chiefly silica gel and active alcohol—it was decided to carry out researches in the use of silica gel for recovery of benzole from coal or coke-oven gas.

Two theories have been advanced to explain the manner in which solid bodies adsorb gases or liquids:

1. *Capillary Adsorption.*—Condensation of the gas or vapour as a liquid in the fine capillaries or pore spaces of the adsorbent. On this assumption, the pore spaces of a given sample of gel being constant, it should take up equal volumes of any liquid whatever, and the gas volume adsorbed would be calculated from the specific gravity of the condensed liquid. This has been shown to be actually the case by exposing silica gel to the saturated vapours of water, benzole, or chloroform. The volume of the liquid taken up was the same in all cases, whether the gel was exposed to the saturated vapour or immersed in the liquid.
2. *Specific Surface Adsorption.*—This supposes that the vapour, instead of being condensed to a liquid in the cavities of the adsorbent, is held by some specific surface attraction at the face of the solid body. This specific attraction between solid and gas molecules, which, it is suggested, may be operative by virtue of unsaturated valencies, would permit adsorption to take place at a plane surface devoid of capillaries. Active charcoal probably adsorbs gases by both the above methods.

After detailing the method of preparing the gel, from 8 p.ct. sodium silicate and hydrochloric acid, a description of various experiments is given, with the data and deductions therefrom. The adsorption efficiency of the gel for benzole was high. With a 9·5 p.ct. benzole content in dry air, a gel containing over 55 p.ct. by weight of benzole was obtained. With a 0·84 p.ct. benzole content in the air, the gel produced contained 13·9 p.ct. by weight of benzole. In these circumstances it was found best to lubricate glass stoppers with *m*-phosphoric acid, and the necessity of avoiding rubber connections was proved, as the latter rapidly adsorbed benzole. The investigations into the adsorption of mixed vapours are very interesting. Commencing with a mixture of water vapour and benzole vapour, it was ascertained that benzole is adsorbed to the extent of about 8 p.ct. of the weight of the gel; but this benzole is gradually displaced until practically the whole of it is removed. The water, on the other hand, gradually accumulates in the gel.

Work was carried out at the Leeds Gas-Works on purified unwashed gas, with the object of discovering to what extent the various hydrocarbons were selectively adsorbed. Much care and clever manipulation were required in the distillations and boiling-point determinations, on about 2 c.c. of the liquid at a time. The results showed that the condensable constituents are adsorbed selectively, and that the water vapour is adsorbed more strongly than the hydrocarbons. Vapours of higher "corresponding pressure" (partial pressure ÷ saturation pressure) than benzole—viz., naphthalene, xylole, and toluole—are adsorbed before benzole itself.

Then followed a series of experiments, using larger quantities of gel, with a view to examining more closely the hydrocarbons recovered from the gas. There was surprisingly little pre-benzole, as this passed through with the gas and was not adsorbed. No carbon bisulphide was found in the lowest boiling fractions, though there was in the crude benzole slightly more than the 0·4 p.ct. of sulphur allowed in the National Benzole Association Specification.

As the volume of gas passed through the gel increased, the hydrocarbons recovered showed a gradually decreasing benzole content, while the toluole and xylole contents increased proportionately. The change in favour of the higher boiling constituents may be due either to an addition of the higher boiling constituents to a gel already saturated with benzole or to a displacement of benzole by the higher boiling hydrocarbons. The experimental data showed definitely that it was the former alternative which actually occurred. Though the percentage of benzole in the recovered hydrocarbons fell from 76·2 to 56·2, the actual amount of benzole in the gel remained constant at about 8·4 p.ct., while the content of toluole rose rapidly from 2·04 to 4·96 p.ct., and the xylole figure also increased, though not so rapidly, from 0·46 to 1·44 p.ct. It was noticed in these larger-scale tests that there was no evidence of water vapour having displaced benzole or toluole from the gel, though the results did not prove that such displacement would not occur if a still greater amount of gas was passed.

By a study of the data and the graphs therefrom, it was possible to arrive at the volume of gas which must be passed through the gel in order to obtain a motor spirit of any desired composition. It is obviously impossible to get a richer benzole mixture than that at the "break-point" of benzole (*i.e.*, when benzole begins to be displaced by higher boiling hydrocarbons), and the composition of the spirit recovered prior to the break-point is the same (77·5 p.ct. benzole, 18·5 p.ct. toluole, and 4·0 p.ct. xylole) however small the adsorption. This mixture is well in advance of the specification fixed by the National Benzole Association for motor spirit; and the composition was easily brought to that specification by passing more gas for a given weight of adsorbent, though it was evident that, in doing this, benzole was being wasted. It is useful to note that the adsorption for a maximum benzole recovery was 9·84 p.ct. by weight (or 13 p.ct. by volume) of the gel, while, if a recovered spirit containing only 70 p.ct. of benzole was required, the adsorption was allowed to rise to 12 p.ct. by weight (16 p.ct. by volume).

The second section is a report by Mr. E. C. Williams on a visit to the semi-large scale plant at Baltimore for the production of motor spirit from coke-oven gas, operated by the Silica Gel Corporation. Claims had been made regarding the production of water-white motor spirit obtained by fractional distillation from the gel; and with the object of inspecting the operation of the plant, a visit was made by Mr. Williams, Mr. Basil Sadler, and Mr. Reavell.

The plant was installed at the works of the Bethlehem Steel Corporation. The gas had passed through the usual Koppers type of coolers, tar precipitators, and ammonia washers before reaching the silica gel absorption plant. At the inlet of the latter the gas temperature averaged 90° to 93° Fahr. (higher than would be the case in normal English practice). The gas was passed through the absorption units at the rate of 75 to 80 c.ft. per minute. The powdered gel was circulated through water-cooled absorbers at the rate of 4 lbs. per minute. Three absorption units were used in series; the fresh gel meeting the gas which had previously passed through two absorption units. In this way the absorption is carried out on a three-stage counter-current system; the gel being carried up each absorption tower by the gas current, separated at the top by a cyclone, and delivered again at the bottom of the next absorber of the series by means of a small screw conveyor. This method of handling a solid absorbent by blowing it along with the gas stream appeared to work excellently and automatically once the flow had been started. The time of contact of the gel with the gas was approximately 7-10ths of a second per absorber, or a total time of contact in three absorbers of about two seconds. The gas velocity necessary for maintaining the circulation of gel was maintained by an exhauster fan at the outlet of the final absorber, capable of maintaining a pressure drop throughout the absorption system of 8 to 10 in. of water pressure. The gas entered the first absorber at slightly above atmospheric pressure, and was evacuated under 4 to 6 in. vacuum. Each absorption unit was water jacketed, to remove the heat developed by the absorption of vapours. The temperature of the cooling water on the plant was high (usually 80° Fahr.), and absorption would, for that reason, tend to be less efficient than might normally be expected, though tests showed an absorption above 90 p.ct. efficiency, indicating that a considerable latitude is permissible in the temperature of the inlet gas and of the absorption chambers.

The gel, after passing through the three absorption units, contains some 7 to 8 p.ct. of absorbed benzole, and about 10 p.ct. absorbed water (the gas being saturated with water vapour at the inlet temperature). After separation in the final cyclone, the benzolized gel is fed by means of a screw conveyor into the top of the primary activator. This is essentially a still for the distillation of the absorbed benzole and water from the gel. It is built in a form similar to the vertical pyrites burners used in sulphuric acid and oleum plants, and consists of a series of horizontal hearths placed vertically above one another. The spaces between the hearths form flues for hot combustion gases from a gas-fired furnace, and the powdered gel is moved slowly downwards from hearth to hearth by a series of rakes fixed to a central vertical rotating shaft. The final

result is that the powdered gel, as it passes through the activator, loses its absorbed vapours, which then pass to a water-cooled condenser, separator, and receiver. The debenzolized gel is discharged at the bottom of the activator. Suitable gel seals of a simple pattern at the gel inlet and outlet of the activator prevent the escape of vapours by those channels. The temperature maintained in this primary activator is 500° to 600° Fahr., sufficient to drive-off from the gel the whole of the absorbed hydrocarbons. The gel, however, on leaving the activator, still contains a certain amount of heavy polymerized or carbonized residue; and, in order to prevent a gradual building-up of such deposit in the pores of the gel, it is passed through a second activator, consisting of a horizontal rotating drum, maintained at 900° Fahr. by means of an external jacket through which hot furnace gases are passed. Sufficient air is admitted to this activator to burn-off the carbon deposit in the gel. On leaving the secondary activator, the gel is conveyed by induced draught to a cooling hopper, from which it again enters the absorption cycle.

At the beginning of the visit the plant appeared to be working smoothly and without the need of any continuous supervision. The benzole recovered, however, was of a dark yellowish-brown colour, while the water layer was black, the latter being due to a fine suspension of carbon. With a view to obtaining a cleaner benzole, much experimental work was carried out. Fractional distillation of the gel by introducing valves into the manifold vapour pipe from the activator hearths was unsuccessful, and radical alterations in the method of heating and operating the activator were also fruitless. A lower temperature and direct steaming of the gel yielded no more promising results.

Tar fog, from which trouble had been anticipated, was not found to interfere in any way either with the efficiency of absorption or, apparently, with the colour of the recovered spirit, though this latter point was uncertain. In direct contrast with plant experience, a sample of benzolized gel as supplied to the activator and distilled from a flask or small iron pan in the laboratory, gave a perfectly satisfactory water-white benzole. It was thought that intimate contact with iron apparatus might influence the colour; but a mixture of fine iron filings and benzolized gel yielded a water-white benzole on distillation. It was mutually agreed that a plant on the lines already proposed would be unsuitable for the production of a saleable motor spirit; and that, if the absorption plant were adopted, it would be necessary to submit the recovered product to some further refining process. The conclusion was a disappointment to the extent that a high-grade motor spirit had not been obtained directly from the benzolized gel. However, attention was turned to the refining action of silica gel in the liquid phase—*i.e.*, by treating with powdered silica gel the crude liquid benzole recovered from the activator. It was found sufficient to agitate the crude benzole with powdered gel in the ratio 3 : 1 or 5 : 1 in a three-stage cycle; the liquid being filtered from the gel between each stage. In practice the treatment was in the nature of a continuous counter-current process. The agitation was carried out in closed vessels, and the filtration conducted by means of continuous Oliver filters provided with gas-tight covers. The gel finally leaving the system contained about 30 p.ct. of absorbed liquid, which was recovered by passing the gel through the primary activator in the manner described above.

There was little apparent difference to the eye between the benzole which had passed the gel liquid-phase cycle and the crude benzole before treatment. There was, however, the very marked difference in fact, that if the treated benzole was now redistilled, it was found to distil water-white over practically the whole range (89 to 92 p.ct.) of the distillation. The final 10 p.ct. was very slightly coloured, but this fraction was obtained entirely above 130° C. and was therefore not employed as motor spirit. The crude untreated benzole, on the other hand, could not be rendered even approximately white by distillation. The explanation of this action of the gel apparently lay in the fact that polymerizable constituents were rendered much more active at the surface of the gel, and became polymerized to high-boiling gums or tars, which, though initially remaining dissolved in the benzole, were of sufficiently high boiling-point to be readily separated by simple distillation. It was thus possible to distil the gel-treated benzole in a still without a dephlegmating column, and obtain 89 to 92 p.ct. distilling below 130° C., and of a quality eminently satisfactory as a motor spirit.

Accurate determinations of efficiency of recovery of hydrocarbons from the gas gave a figure of 97·9 p.ct. A recovery of liquid benzole from the gel of 95·6 p.ct. efficiency was obtained. Thus a yield of crude benzole equal to 93·6 to 95 p.ct. of the amount initially present in the gas was possible. This contained 0·37 p.ct. of sulphur. The semi-large scale distillation of the gel-treated benzole yielded 88·8 p.ct. as saleable motor spirit. If 2 p.ct. loss was allowed in the liquid-phase process (it was probably 1 p.ct. or less) the over-all recovery of refined motor spirit was equal to 80 to 82 p.ct. of the total hydrocarbons in the gas.

In passing, it may be noticed that the standard colour test for "water-white" is accepted generally in America as anything less than the colour of a solution of 0·003 grammes of potassium dichromate in one litre of water.

Comparison of the gel-refined benzole with the requirements of the British Engineering Standards Specification for motor benzole showed that, with the exception of the sulphuric acid wash test and the freezing-point, the gel-recovered product was able to meet the present British specification. This raises the question of the suitability of the sulphuric acid wash test, in view of the recent developments in motor fuel technology. It is true that sulphuric acid refining of benzole has a positive value in removing harmful constituents which cause discoloration and gumming; but the harmless unsaturated compounds are removed at the same time, and these latter are a valuable portion of the motor spirit. Certain systems, of which the silica gel process is an example, conserve these unsaturated compounds; but as the latter show coloration with sulphuric acid, benzole refined by such methods will not pass the acid test, and yet may be perfectly suitable as a motor fuel. Thus an alternative to the acid test was sought, and one of the suggestions made to the National Benzole Association was the copper dish test, in which 100 c.c. of the benzole are evaporated to dryness in a weighed bright copper dish. The copper appears to accelerate the polymerization of the resin-forming constituents, and the latter remain as a dark varnish in the dish. If the spirit contains deleterious sulphur compounds, the surface of the dish is corroded. A trial run for about 45 hours on the silica gel spirit in a motor engine gave results which showed little difference from those obtained with acid-washed benzole in a similar engine. The test would have been of more value had the period of trial been a much longer one.

From the approximate cost sheet given in a short report by Mr. Basil Sadler, about one-quarter of the 5·57d., which is the cost of production per gallon, is due to gel replacement and royalty.

As regards the properties of silica gel prepared by different methods, Mr. E. C. Williams reports in a short note that silica gel prepared by adding silicon chloride to water with vigorous agitation is quite as good as that made from sodium silicate and hydrochloric acid, and has the added advantage of being entirely free from sodium chloride, which is never completely eliminated from the silicate product, even by exhaustive washing. Alkali salts greatly accelerate the conversion of amorphous silica to one or other of its crystalline forms at temperatures ranging from 700° to 1000° C.

The latter part of the report of the Benzole Research Committee for 1924 deals mainly with the purification of benzole by means other than washing, a description of an improved method for determination of sulphur in benzole, and experimental work with the object of finding a reliable method for determining the unsaturated hydrocarbons in benzole. Owing chiefly to the production, by cracking, of spirits containing up to 30 p.ct. of unsaturated hydrocarbons, a method of refining other than by means of sulphuric acid would be welcomed by producers of motor spirit. With this object in view, experiments were carried out using intensive oxidation to accelerate the production of insoluble resinous matter by the gum-forming constituents of unrefined benzole. It was found that the passage of air at atmospheric pressure caused little change, so air oxidation under pressure (200 to 400 lbs.) was tried, at varying temperatures. The results were interesting, and showed that the content of unsaturated hydrocarbons could be reduced in a short time to an extent almost equivalent to that obtained by the usual sulphuric acid washing process. The distilled benzole after treatment was still nearly water-white after six months' exposure to full daylight, while the untreated benzole developed a strong yellowish-brown colour. The experiments were unfinished when the report was published.

The chief difficulty in investigating these oxidation reactions was the lack of an analytical method which would give a measure of the resin-forming constituents in the benzole; and such a method is provisionally put forward. This depends on the determination of the bromine addition value of the spirit before and after the removal of the gum-forming constituents by refluxing with sodium strips for two hours. This entailed an investigation of the methods available for the determination of unsaturated constituents in benzole; and the conclusion was drawn that the acid washing test and the permanganate (oxygen absorption) test have sources of error. After an exhaustive examination of Wij's method of determining the iodine value of an unsaturated substance, it was found that the iodine value for a benzole was, at the best, an empirical one which is dependent to a considerable extent upon the conditions under which the determination is made. McIlhiney's method for the separate measurement of halogen addition and substitution values was then investigated; and the report states that this method is the most satisfactory one yet examined for determining total unsaturation.

In conclusion, an improvement is suggested to the method recommended by the British Engineering Standards Association for determination of sulphur in benzole—drawing the benzole vapour, with secondary air, over heated platinized silica and absorbing the products of combustion in sodium hypo-

bromite solution. As it is difficult to vaporize the benzole completely from the cotton wool used in the test, the modification suggested is the use of silica gel instead of cotton wool. From this gel the benzole is given-off slowly and continuously into the air stream, and is completely volatilized by heating to red heat towards the end of the test.

CULTIVATION OF DOMESTIC AND OTHER COKE MARKETS.

[From a Paper by E. W. Smith, D.Sc., F.I.C., and F. S. Townend, B.Sc., before the Midland Institute of Mining Engineers.]

Coke satisfactory for domestic work should have the following properties :

(1) Good combustibility.
(2) Low ash, sulphur, and moisture
(3) Uniformity of size, the coke being screened and sized to suit the particular purposes.

We would urge that the last two items are of paramount importance, and that improved combustibility, even with cokes as produced to-day, would follow if these requirements were given adequate attention.

Requirements of Coke

Up to the present there appear to be no comprehensive specifications to which the various classes of coke should conform. Such as have been proposed are confined largely to the ash, sulphur, and moisture contents, together with the appearance and hardness. The absence of any reference to the property known as combustibility is probably due first to the fact that it is only during the last few years that it has been realized that this property plays so important a function as it undoubtedly does, and, secondly, to the fact that there is no satisfactory test which gives results indicating precisely the value of a coke's combustibility.

Combustibility.—The usual methods of determining reactivity adopted by Wheeler, Bähr, and other investigators consist in passing oxygen or carbon dioxide through a layer of coke heated to a definite constant temperature; the resulting gases being subsequently analyzed, and a formula used to express the analysis in terms of a constant. This method is essentially a laboratory one, and depends on the particular conditions of temperature and time adopted in the experiment. While yielding results of interest, it appears that, for the practical working of a specification, a more robust test is required.

H. Koppers has shown that when coke is burnt in a fuel-bed of definite thickness by blowing it with air at a definite rate, the length of flame above the fuel-bed is a measure of the combustibility. A modification of this same method has found a certain amount of favour, especially in America. A small vertical refractory-lined shaft is built about 5 ft. high and 18 in. in inside diameter. The base of the shaft is fitted with a grate, beneath which is a closed ashbox, into which can be blown air at any definite rate. The sample of coke is carefully screened and sized, and a definite quantity dumped on to the grate in the shaft. A coal-gas jet plays for a certain time on the lowest layers of the coke, to start combustion, and then a definite quantity of air is admitted under the grate according to a pre-arranged schedule. After the lapse of a stated interval of time, the coke which remains unconsumed in the furnace is dumped into the ashbox, cooled, and weighed. The percentage of the carbon burnt is a measure of the combustibility of the coke. By this method a fast-burning coke will show a percentage of carbon burnt of 90 and more, and a slow-burning one about 60 p.ct. This test undoubtedly gives a figure which shows the combustibility.

Coke Structure.

Stress has been laid on the question of the combustibility of a coke; and it will be of interest to review the factors on which this property appears to depend.

Coke structure may vary in the following particulars :

(1) Size and uniformity of pores and connecting passages.
(2) Amount of space occupied by the pores and passages (porosity).
(3) Thickness of the cell walls.
(4) Nature of the cell walls.

The high absorptive capacity of charcoal depends not wholly on the total porosity, but on the presence of innumerable small pores and passages of minute dimensions. As charcoal is the most easily combustible carbonized fuel known, there is little doubt that its high absorptive capacity and combustibility are intimately connected. It is probable, therefore, that the size of cells, unless they be of dimensions of the order of 1×10^{-8} cm. have not a great influence on combustibility. Nevertheless, since uniformly-small cells present a greater surface per unit of cell volume than large and irregular-sized cells, they must tend in the direction of greater combustibility.

The percentage of the volume of coke occupied by cells is not in itself a good criterion of combustibility, as a given percentage of cell volume may be disposed either as large pores and thick walls or as small pores and thinner walls. The apparent specific gravity, which is the actual weight of coke-substance in a given volume of coke, is a better indicator of combustibility, for it may be said that a coke having a lower apparent specific gravity will in all probability be more combustible than one of higher apparent specific gravity. The degree to which the size, uniformity, and amount of pores can be modified in the coke-oven is somewhat limited, and it is doubtful whether the difference in combustibility between charcoal and coke can be much reduced unless grinding and blending along the lines suggested by Sutcliffe and Evans are adopted.

Thickness of Cell Walls.—The factors of the thickness and nature of cell walls are, however, susceptible to considerable modification in the coking process.

Greenwood and Cobb have shown that the thickness of the cell walls undergoes considerable change according to the temperature to which the coke is subjected. The results of their experiments demonstrated that up to temperatures of 550° C. the coke was soft, with thick walls and low specific gravity. Between 550° and 850° C. the walls were thinner and the specific gravity was greater. At higher temperatures there was a large contraction of the coke. The walls became thicker, the pores smaller, and the specific gravity further increased. This would appear to point the way to a coke produced at temperatures below 850° C. as being necessarily more combustible than a high-temperature coke.

It must be pointed out that, in addition to the temperature, the duration of the coke at the particular temperature must be taken into account. There appears to be no evidence that a coke which has never been subjected to a temperature greater than 850° C. is necessarily more combustible than a high-temperature coke from the same coal, which coke has not been subjected to long baking at that temperature. Comparatively low temperature coke is less strong than that formed at higher temperatures; and the advantages to be gained in the way of increased oven outputs by the use of fast coking times would seem to mean that increased combustibility must be sought by reduction in coking time rather than by the use of lower temperatures.

Nature of Cell Walls.—It has formerly been accepted that the comparative incombustibility of coke has largely been the result of a deposit of graphitic carbon on the cell walls, resulting from the decomposition of ethylene, methane, &c. Recent conceptions of the nature of the cell walls lead to a modification of that view. It has been calculated that under the worst conditions the thickness of the cell walls is some thousand to ten thousand times that of any graphitic deposit likely to be formed, and the conclusion seems fully justified that, though the ignition temperature may be affected, it must be the nature of the cell walls, rather than the deposit, which determines the combustibility.

Blending.

During the past few years, the question of the scientific blending of coals has received considerable attention from many workers. Interest in this subject was again revived by the paper by John Roberts read before the North of England Institute of Mining and Mechanical Engineers in 1921, in which the following principle was advanced :

" The maximum rate of heat-transfer through the mass, consistent with the formation of suitable coke, is obtained only when the condition of the charge is such that no excess binder is present."

Heat-penetration curves were published in support of this view. This work has been confirmed by Weyman, E. V. Evans, and ourselves. The improved heat-transmission results from the restriction of the development of the plastic layer, which acts practically as a non-conducting zone. We concur in Mr. Roberts's view that slow coking in wide ovens results in the destruction of the excess binder of strongly-coking coals; heat energy being needlessly used up in the destruction of this binder. In order to employ the binder usefully, and at the same time to affect great improvement in the rate of heat-penetration, Roberts proposed that all strongly-coking coals should be blended with inert substances such as coke-dust and non-caking and feebly-coking coals.

We are satisfied from the results of our experiments that judicious blending undoubtedly does produce the effects described, prevents expansion of the charge, and reduces the coking time; the resulting coke being of a uniform and strong nature. Narrow ovens which ensure rapid, uniform heating can, of course, employ larger proportions of inert coals than can be used in wide ovens.

The Gas Turbine.—Mr. König, in a paper presented to the North-East Coast Institution of Engineers and Shipbuilders, pointed out that a wide field of application for a successful gas turbine was represented by power plants operating on gas from blast furnaces, coke ovens, and gas producers. A successful gas turbine, furthermore, became of increasing importance with the trend—faintly marked as yet—to avoid the wasteful direct burning of coal by the adoption of low-temperature gasification on a large scale. In this case the direct use of the gas in internal combustion turbines would seem to be the most economical procedure.

RIVER POLLUTION.

The Tar and Bitumen Question.

The Standing Committee of the Ministry of Agriculture and Fisheries, dealing with the subject of river pollution, have issued Part 2 of their report. This constitutes a non-technical statement on the work carried out during 1924, as well as an outline of the scheme of scientific work which it is proposed to undertake in the immediate future. During the twelve months, it appears that the work of the Committee has continued on an extending scale, and yet they have not been able to comply with the whole of the applications for investigation and advice which have reached them. They believe that their labours, so far, have caused public opinion to be more alive than heretofore to the fact that filthy rivers are not a necessary accompaniment of advanced civilization. In continuation of the practice the Committee adopted from the outset, scientific investigations of the effects upon fish of various polluting effluents have been carried out, and by co-operation between the Committee and industrial firms remedies have been found for, and applied to, a number of specific pollutions.

In the present report the Committee deal largely with the condition of rivers as revealed by inspection and survey, and also with the scientific aspects of pollution. It is clear from what is said that a large proportion of the pollution which is deleterious to fish life is caused by sewage works, and by the effluents of different industrial processes. But a matter which requires very careful research is that of the effects of the complex pollutions caused by the mixture of different polluting effluents. Those views are gathered by a perusal of the reports on the conditions of the different rivers; but we will here confine ourselves to a reproduction of points made by the Committee in which gas-works are interested. From these it will be seen that the Committee are very definitely of opinion that the tar dressing of roads in proximity to rivers and streams in which there is fish life is culpable for much of the destruction that occurs. Furthermore, they are distinctly of the view that in such cases bitumen should displace the tar dressing.

Dealing with the River Wear, it is stated that the tidal waters are rather heavily polluted by coal mines, coke ovens, chemical works, gas-works, and sewage. Then as to the River Tees, it is stated that the upper waters are in good condition, but the lower waters are badly polluted. Scientific observation has found that the water is heavily charged with products of a tarry character which are deadly to fish. In addition, it is stated, effluents have been analyzed and found to contain large amounts of tar products and of acid from pickle liquors. In this case a Joint Committee has been formed of representatives of the Tees Fishery Board and the manufacturers, to take in hand the examination and improvement of the industrial effluents discharged into the river; the expenses being borne jointly. It is hoped that some of the various methods of treatment of coke-oven effluent will be tested-out under the ægis of the Joint Committee, with a view to the discovery of the most effective and practicable processes. In referring to the River Trent, an observation is made as to the River Erewash receiving a number of effluents from coke ovens. Independent analyses of the waters of the River Wye (Derbyshire) have indicated sewage pollution and the presence of tar acids. That was in July last. In the following month the river was examined both chemically and biologically; and the results showed that the chief sources of pollution were from the roads and a gas-works. At the time of the survey, road-tarring operations were in progress, and it was obvious that the washings (there had been heavy rain) were running into the river. Samples taken from puddles in the road showed, on analysis, appreciable quantities of tar acids and tar bases; and samples of the river water itself also contained tar. In addition, mud taken from below a gas-works discharge-pipe had a distinct smell of "coal gas," and also contained a considerable amount of tar, which, it is thought, could not have been derived from road washings. The question has been taken up with the Highway Authorities concerned; and it is confidently anticipated that as a result some, at any rate, of the causes of the deterioration of the very valuable Wye fisheries will be removed.

There is no more indictment of tar until we come to the River Darent. In this case, from 1908 the stock of trout in the river rapidly diminished despite re-stocking, and there are now no fish at all. From information supplied to the Committee, they state that the decline synchronized with the commencement of the practice of tarring the roads in the vicinity; but while the tarring of roads appears to have been the primary cause of the pollution, there were certain other minor sources, and the whole effect has been accentuated by the reduction of water in various lengths of the river through the sinking of wells in the valley. A survey at the end of May, 1923, definitely established the presence of tar acids in the water. It is understood by the Committee that the Kent County Council are gradually re-surfacing with bitumen the roads which drain into the Darent; but owing to their considerable mileage it has not yet been possible to deal with all of them. As soon as the re-surfacing is complete, it is hoped that successful re-stocking in the river may be commenced. Regarding Hampshire rivers, the Wylye between Warminster and Salisbury is reputed to be suffering as a result of road tarring in the vicinity. A visit to the river and the adjoining roads revealed the fact that, as a whole, the roads are now satisfactorily treated. Some local authorities, however, are still using tar dressings, and the Ministry of Transport, at the request of the Fisheries Department, have taken up the question with the authorities concerned. In connection with the pollution by tarred roads of the Itchen between Winchester and Eastleigh, the Test and Itchen Trout Fishing Association convened a meeting in February, 1924, at Winchester, in order to discuss with the local Highway Authorities concerned the desirability of substituting bituminous road dressings for tar on roads draining into the river; and, as a result, an agreement has been arrived at which should ensure that no further pollution from this source will occur in the future. In other directions we see that lead-mining operations are also arraigned for their polluting propensity.

The next section of the report deals with future work, and it is held that for the maximum usefulness progress must be made along lines of scientific investigation. From this section, we quote *in extenso* the following portion:

"In this connection the Committee desire to allude again to one topic dealt with in their first report—namely, the effect upon fish of the washings from tar-dressed roads—because the investigation of that subject has produced definite conclusions which have been successfully put into practice in many places, and are capable of still wider application. The Committee desire to emphasize the fact that the experiments conducted by the Fisheries Transport Committee (upon which a report will very shortly be issued) showed conclusively that washings from a tarred road killed fish, though the degree of toxicity varied according to the state of the road; the most toxic washings being obtained immediately the tar was applied and when the surface of the road was breaking up. It is obvious that if there is no rain immediately after the tar is laid, only slight damage may result for a time—particularly if the river concerned is a large one. But there is always a risk that a sudden downpour will occur as soon as the tar is laid; and, in such a case, all the fish in a large stretch of river may be exterminated; and the danger is no less when the road breaks up.

"As far as tests have shown, whenever a compound road material is used which contains an appreciable quantity of tar, it may be anticipated that at some time or another in the history of the road the rain washings will be of a toxic character. On the other hand, the experiments carried out by the staff of the Fisheries Department with bitumen showed conclusively that even undiluted washings from bituminous surfaces were harmless. The Committee are glad to know that the substitution of the bituminous road dressings for tar on roads, the washings from which may gain access to fishing streams, is progressing all over the country; but isolated cases have been brought to their notice in which the surveyors of local authorities hold firmly to the opinion that tar is not injurious to fish—basing this opinion on their personal observations in their local streams, or on statements that have appeared in trade journals. It cannot be too emphatically stated that this opinion is entirely contrary to the facts as disclosed by the reports of the Joint Fisheries Transport Committee.

"In the case of road tarring, it was possible, by a comparatively simple experiment, to demonstrate its inevitably prejudicial effects upon fisheries, and by similar experiments to demonstrate the harmlessness of washings from bituminous roads. The Committee therefore, being in a position, not merely to point out the deleterious effects of tar, but also to indicate a simple remedy for them, felt justified in pressing, and pressed successfully, for the application of the remedy. Similarly, wherever they become aware of a specific pollution for which they can offer a practicable remedy, whole or partial, it is their policy to press for the application of remedial measures. This policy, which has been attended with encouraging results in the past year, will be steadily pursued in the future. But the number of cases of general pollution for which simple and practical remedies can be suggested is, as yet, small; and the Committee, conscious of the difficulty and complexity of the scientific problems, the solutions of which must precede the effective treatment of pollution in general, asked early in 1924 for the support of a scientific advisory body, to ensure that future work should be conducted on lines both practical and scientifically sound."

To that end, the Ministry have appointed a Scientific Advisory Committee to advise the Standing Committee on all purely scientific questions. This Committee is constituted as follows: Prof. A. E. Boycott, F.R.S. (Chairman); Dr. H. T. Calvert, D.Sc., Ph.D., F.I.C.; Mr. J. H. Coste, F.I.C., F.Inst.P.; Dr. H. H. Dale, C.B.E., F.R.S.; Dr. J. A. Gardner, M.A.; Dr. E. C. Jee, D.Sc., F.I.C.; Mr. G. Bertram Kershaw, M.Inst.C.E.; Prof. E. W. M'Bride, F.R.S.; Sir Robert Robertson, K.B.E., F.R.S.; Dr. E. S. Russell, D.Sc.; and Dr. E. J. Salisbury, D.Sc.

Finally the report deals with the programme of research approved by the Scientific Advisory Committee. It consists of river surveys, physiological tests of effluents, examination of dead fish, analysis of effluents, tests of constituents of effluents, and purification of effluents, with an investigation of the general problem of the relation of fish life to pollution.

Annual General Meeting of the "S.B.G.I."—As already announced, the annual general meeting of the Society of British Gas Industries will be held in the Hotel Cecil, London, W.C., on Wednesday, May 20—Mr. D. Milne Watson, D.L., M.A., LL.B. (the President), in the chair. At 2.30 there will be the general business meeting, and this will be followed at 3.30 by the President's Address, and the induction of the new President (the Right Hon. Sir Alfred Mond, Bart., M.P.). At 7.30, in the Hotel (Embankment Entrance), the annual dinner will take place.

GAS STOCKS AS GILT-EDGED INVESTMENTS.

By C. B. Tully.

Not many years ago, the majority of gas investments were considered gilt-edged securities. Even the smallest village works was a sound dividend-earning proposition; and there is no reason why this should not be so to-day. It does not reflect credit on the gas industry to see so many of the small concerns —often the pioneers and the first works started in the country— closing down. No doubt this state of affairs is largely attributable to the war and its consequent economic disturbance; but I think it is hardly to be disputed that too many of the smaller works have failed to keep pace with the general development of gas manufacture. Notwithstanding the increase in cost of coal and labour, and the unremunerative price obtained for coke, many works still carry on, upon the identical lines of fifty years ago. Why this should be, it is difficult to understand.

A few years ago the writer caused some amusement by describing a small village works that closed-down for the week-end while the manager went to the seaside. There are now works of 20 million c.ft. per annum, and many others, making all the gas they require in eight hours, and closing-down for the remainder of the day, without any loss whatever. Many small works have been put on a sound financial footing, especially in Scotland. One instance is a works of 9 million c.ft. per annum, which was purchased for £5000. This is selling 12 millions, and is making a profit of over £800 per annum. This is only one example among many works that might have been closed-down, but which have been saved from ruin and rendered prosperous.

A number of these small concerns, no doubt, started to get into financial difficulties during the war, or during the several unsettled years that followed, with the result that they are now —especially with the present slump in coke—unable to show a satisfactory balance, while the drained reserves render the purchasing, from funds in hand, of new and up-to-date plant impossible. There should, however, in most cases, be no great difficulty in finding the necessary extra capital to provide modern plant, and put these concerns on a sound financial basis. It is faulty management to allow matters to drift from bad to worse; and with the vanishing coke market, and the dumping that will take place, it is more important than ever to deal with these concerns on genuine business lines.

A gas concern has to make a profit to live; and to do so it does not matter what standard of gas supply is adopted, be it 500 or 350 B.Th.U., so long as it gives satisfaction to the consumers. It has been established now beyond dispute that gas of 350 B.Th.U., if properly handled, will give all-round satisfaction whatever the use to which it may be put, and will earn a dividend for the shareholders. To adopt 350 B.Th.U. gas, and complete gasification of coal, converts a gas-works into a gas-generating station, and does away with all the worry and anxiety attached to the sale of coke. Of course, it is quite understood that many of the large gas undertakings cannot drop the calorific value on account of distribution troubles; but in smaller concerns such troubles can be overcome, always having in mind the £ s. d. view of the matter.

The coke market is, and always will be, an unsatisfactory business, for, should a small concern go to the trouble of studying the local coke market, and make a good soft coke, some large company or factor will start dumping inferior coke on them, and will ruin their market. Taking everything into consideration, it is better to restrict the manufacture of coke as much as possible, or cut it out altogether, as many of the American companies have done. The present slump in the coke market is not at all a temporary matter. It has come to stay; being primarily due to the over-production of oven coke. On the Continent, coke-ovens are closing-down, as there is no market for the coke, and they cannot carry on at a profit. In America there is a vast over-production of oven coke, there being at present more than one-and-a-half million tons in stock. This has a poor demand at 7s. per ton; but there is little fear of competition, as it costs 20s. to freight it to the coast. Something has to be done, and that quickly. It is poor business, as is being done in some cases, to buy coal at 26s. per ton, and have to sell coke at 20s.

The writer has no axe to grind for anyone, and is not associated now with any low-temperature concern; but he does think that the gas industry should turn its attention most seriously to the important proposition of the low-temperature carbonization of coal and to the manufacture of smokeless fuel, and not leave it to outsiders. The manufacture of this fuel will provide about 50 therms of enrichment per ton of coal treated practically for nothing. This is a sound proposition, and would save buying oil abroad and sending much-needed money out of the country. One ton of slack coal carbonized at low temperature will produce 40 therms of rich gas and 10 therms of gas oil—together equivalent to 50 gallons of gas oil; also 14 cwt. of smokeless fuel, and 10 gallons of heavy tar. Work it out, and it will soon be seen what there is in the proposition.

EVOLUTION OF THE VERTICAL RETORT.

In connection with the admirable paper by Mr. Walter T. Dunn, reported in our April 22 issue, comment has been excited by the omission, though chronological order was stated, of any detailed descriptive paragraph of the "Dempster-Toogood" system of continuous verticals. This system was, in the author's résumé, chronologically No. 8, and was fully represented at the lecture by illustrations, drawings, pamphlets, and working models, for the loan of which due acknowledgment was made to Messrs. Robert Dempster & Sons, Ltd., of Elland.

Mr. Dunn chronologically dated this system for 1912; and though the principle of continuous carbonization is the same in all vertical retorts, the advent of the "Dempster-Toogood" system was marked by the thoroughness of the development of each of its many detail departures, and by the ingenuity with which all its details were rendered subservient to the main essential—viz., the continuity of descent by gentle gravity alone.

The Dempster-Toogood system is chiefly characterized by:

Its extended portion of brickwork (coming immediately beneath the heated retort, and above the coke-extracting mechanism) being made always of larger cross-sectional dimension than the retort itself, whereby the descending coke formation is opened out into coke pieces, for the better intermingling of steam, and for the more ready cooling and preparing of the coke before extraction.

Its coke-extracting mechanism, consisting of an adjustable reciprocating tray, performs two functions, for not only does it regularly extract the coke, but the known tendency of coke to bridge-over is, by this unique two-fold motion, overcome to the advantage of continuity of descent.

Its central ingress for coal at the top of the retort, whereby the natural phenomenon of rolling nuts is utilized advantageously to build a balanced charge of coal.

Its disposition of maximum temperatures; the active flames of combustion being 6 ft. down from the top of the retort, then burning downwards, and afterwards crossing the extreme top of the retort, to regenerate the cold incoming coal, whereby the most highly stressed or highly heated refractories are in such a safeguarded position as to be (*a*) relieved of the erosive effect of moisture in down-coming coal or rising steam, (*b*) out of reach of harm by stoker's bars, and yet, while relieved of excessive weight of superimposed brickwork, (*c*) in relatively easy reach for economic re-setting.

Its double tapered retort, offering maximum taper to the swelling coal above, and minimum taper to the shrinking coke beneath.

The system is well represented in the southern counties; the Great Western Railway having chosen it for providing the huge quantities of gas required for the modern shop practices in the speedy heat treatment of metals.

They have installed a very complete 3,000,000 c.ft. per day plant at their Swindon Works, and the various uses they make of this amazing quantity of gas were exemplified in a recent issue of "A Thousand-and-One Uses of Gas."

United States Gas-Works Statistics.

Statistics compiled by the American Gas Association show that the manufactured gas companies of the United States in 1924 sold 405,000 million c.ft. of gas—an increase of 20,000 million c.ft. over the preceding year. In the last six years the sales have gone up no less than 100,000 million c.ft. New customers taken on last year numbered 440,000, making a total of 10,240,000 at Dec. 31 last. The sales of appliances for the year reached 800,000 gas ranges, 450,000 water heaters, and 500,000 heating stoves—truly inspiring figures for the salesman. At the same time, the use of gas in industrial processes is progressing at an unprecedented rate; the sales in this one field alone during the last ten years showing a growth of 1000 p.ct. Another large-volume business of an attractive character has been found in complete house heating, for which installations are now being put in at the rate of 10,000 a year.

Heating Calendar Rolls by Gas.—The application of gas to the heating of calendar rolls in a plant at Pawtucket was cited by Mr. C. S. Hilton, of the Blackstone Valley Gas and Electric Company, Pawtucket, in a paper which he read before the New England Association of Gas Engineers. These rolls had previously been heated by steam. Condensation of the steam inside the rolls, however, limited the temperature which could be reached. When gas was utilized as the heating agent, the application was made in such a manner as to bring the temperature to the highest safe point, thus materially speeding-up the production, and giving the machine an output greater than would have resulted otherwise. Floor space and other savings resulting more than offset the cost of gas.

NORTH OF ENGLAND GAS MANAGERS' ASSOCIATION.

Annual Meeting at Newcastle-on-Tyne.

THE Annual General Meeting of the North of England Gas Managers' Association was held on Friday, May 1, at the County Hotel, Newcastle—Mr. S. SHADBOLT, the President, in the chair.

Mr. NORMAN S. COX, Hon. Secretary and Treasurer, announced that letters of regret for absence had been received from Mr. C. H. Armstrong, Mr. Blundell, Mr. Doig Gibb, Mr. Shapley, Mr. Rufthead, and from Presidents and Secretaries of kindred associations.

The statement of accounts for the past year had been circulated among the members, and was submitted by the PRESIDENT. This was adopted on the motion of Mr. T. LAW, seconded by Mr. F. C. WILLIS.

The PRESIDENT moved the confirmation of a recommendation of the Committee that a donation of £10 10s. be contributed to the Benevolent Fund of the Institution of Gas Engineers. He said it was a small sum for a very worthy object.

Mr. C. DRU DRURY seconded, and the motion was agreed to.

Transfers to full membership: Mr. J. E. Dixon, of Elswick; and Mr. C. S. Read, of Washington.

ELECTION OF NEW MEMBERS.

Member, Mr. W. Millard, of Bridlington. Associates: Messrs. J. E. Wakeford, of Stockton; A. H. Nicholson, of Stockton; S. W. Scurr, of Monkseaton; T. Rudd, of Sunderland; and J. W. Pallister, of Middlesbrough.

EDUCATION SCHEME.

The PRESIDENT reported on the action of the Committee, on a recommendation from the Special Purposes Section, since the last meeting of the Association, in connection with the Institution Education Scheme. Most of the members would be aware, he said, that in various districts a local committee had been appointed as an advisory committee for local purposes—a body to whom students might refer in any case of difficulty or misunderstanding, so that someone with a little status, and representing local interests, might be there to advise and help them. During the last six months the Committee appointed a Sub-Committee to consider the scheme; and it had been proved to the mind of the Committee that it would be a good thing if they copied the example of other districts, and appointed a local committee to advise between the students and the central authority. Mr. Shadbolt had been convener of the Special Committee, which comprised, with power to add to their number, Messrs. C. Dru Drury, A. W. Branson, F. P. Tarratt, Herbert Lees, and W. W. Atley.

Mr. T. P. RIDLEY moved the confirmation of the Special Committee; and this was agreed to.

SOME EXPERIENCES WITH GASHOLDER TANKS IN A MINING AREA.

By CHAS. DRU DRURY, of Sunderland.

The gasholder tank is an important item in the equipment of a gas-works, not only on account of its initial cost, but also from the fact that any defect in its soundness has a serious effect on the holder of which it forms a part. The design and construction, therefore, of a tank on ground liable to subsidence require serious consideration by the responsible engineer.

As is well known, gasholder tanks are constructed of various materials and in various manners. Cast iron, stone, bricks, concrete, reinforced concrete, and steel have been used for this purpose. Where the formation of the ground necessitates, tanks, annular in shape, have been cut out of the rock and lined with water-proofing material. Tanks are constructed wholly in the ground, or partly sunk, or built wholly above ground, to suit varying conditions and requirements; but, of course, none is wholly proof against the effects of subsidence, should it occur. Even a "tankless" holder in like circumstances would not be immune from trouble. The writer trusts that the following detailed account of experiences, with which he has been more or less intimately associated, will be of interest.

A brick tank 85 ft. 6 in. in diameter, by 22 ft. deep, entirely sunk in the ground, with puddled domed bottom and puddled backing to the wall, constructed nearly fifty years ago, had originally contained a single-lift column-guided holder. This holder was subsequently replaced by another of three lifts, spiral-guided. Shortly before the conversion, a deep pit shaft had been sunk by a colliery company, and coal workings begun in the immediate neighbourhood, followed by the appearance of cracks in several buildings in and around the works. Considerable trouble was also experienced from broken gas mains and drawn joints in the district. After the new holder had been at work for a short time, loss of water was detected, and the tank was found to be 1¼ in. out of level. The leakage increased to such an alarming extent—the drop in the water being about 17 in., or 45,000 gallons, in 24 hours—that the holder had to be landed, and the tank emptied. On examination of the interior, it was found that there were no less than 12 vertical cracks in the wall, varying respectively from $\frac{1}{8}$ in. to $\frac{1}{2}$ in. in width. The lifts of the holder were raised, to enable the wall to be repaired, which was effected by cutting-out the brickwork where the worst cracks were found, grouting with cement, and making the brickwork good again. The finer cracks were grouted and pointed up.

When refilled, there was still a slight loss of water from the tank, amounting to about 2500 gallons per day; and this leakage has continued, but without increasing, for the past three or four years. The leakage is, however, made up by turning on a supply of water from time to time. The tank having been weakened by the movement of the ground, it was considered unwise to submit the tank wall to the stresses transmitted to it through wind pressure acting on the holder when fully inflated; and it was therefore decided that no more than two of the three spiral lifts should be used in future.

A small two-lift spiral holder in a steel tank 75 ft. in diameter by 20 ft. deep was erected above ground on a reinforced concrete raft, 12 or 13 years ago. There was general evidence of subsidence in the district; and when some alarming cracks developed in the buildings in and around the gas-works, the position was carefully looked into, and the tank was found to be 5⅜ in. out of level—the tilt being in a direction which clearly indicated the source of the trouble. It will be recognized that a serious situation had arisen when a two-lift spiral holder was compelled to work under such an adverse condition; and it was decided that the holder must be laid off, and the tank emptied and re-levelled on its foundation.

A cast-iron tank 62 ft. in diameter by 18 ft. deep, containing a three-lift column-guided holder, having a capacity of 130,000 c.ft., was erected in 1881 on the site of an older brick tank, and was sunk in the ground to a depth of 10 ft. The side was formed of four tiers of plates 4 ft. 6 in. square and about $\frac{3}{8}$ in. thick, with flanges strongly bracketed between bolt holes, and the plates themselves stiffened by external diagonal ribs. About thirty years after its erection a slight loss of water in the tank was noticed. It was also discovered that the tank was 2½ in. down on one side, and that cracks had developed in one or two of the adjacent buildings. The leakage which was slowly increasing amounted at that time to about $\frac{3}{8}$ in., or 600 gallons, per day; and as none was visible externally, the ground against the side of the tank was excavated in likely places, and a crack was found running vertically through two plates in the two lower tiers, and from it water was freely issuing. The holder was landed and the water pumped out of the tank, the lifts of the holder being raised some 10 ft. to enable the inside of the tank to be inspected thoroughly. The full extent of the crack was located, and a small hole was drilled at each end to prevent it from spreading. A steel plate 9 ft. 6 in. long, 3 ft. 4 in. wide, and $\frac{3}{8}$ in. thick was procured, bent to the curve of the tank and bolted over the crack inside the tank; the joint between the steel and cast-iron plates being made with felt well soaked previously with red lead paint.

In addition to the crack referred to, one or two smaller cracks were found in the bottom radial plates; and these were also patched on the inside with steel plates secured by tap bolts. During the repair of the cracks, water accumulated in the excavation which had been carried down to the bottom of the tank, outside; and this water was kept-down by pumping until the patching had been completed. When all was finished, the pumping was stopped one morning; but later on that day, well into the afternoon, a report was heard all over the works, emanating from the gasholder, when it was found that twenty of the radial tank plates had burst upwards, and that water to a depth of about 6 in. was lying over the bottom of the tank. These plates had cracked at a distance about half-way between the centre and the side of the tank; and the crack extended for a length of about 48 ft. When the broken plates were removed, it was found that the tank had originally been bedded on coarse rubble; and owing to the water-logged nature of the ground round the tank, the head of water which accumulated as soon as the temporary pumping had been stopped was sufficient, with the tank empty, to burst-in the bottom. The damage was repaired by obtaining and fixing new cast-iron radial plates.

In order to consolidate as far as possible the rubble under the bottom, cement grout was run in through a ¾-in. hole drilled in every alternate bottom plate; the holes being subsequently tapped and plugged-up. The tank, when filled with water, was found to be perfectly tight, and has remained so ever since—a period of fourteen or fifteen years. While the tank was being filled, and until it was nearly full, large bubbles of air were noticed coming at intervals from under the bottom and breaking through the water which had collected in the excavation outside. This phenomenon was no doubt due to the weight of water inside the tank flattening that portion of the bottom which had lifted slightly when it had burst upwards.

A brick tank 72 ft. in diameter by 20 ft. deep, entirely sunk in the ground, with puddle backing, contained a single-lift

Fig. 1. Fig. 2. Fig. 3.

column-guided holder. The history of this case is that some fifteen or sixteen years ago the side of the tank cracked badly in two places—clearly the result of subsidence—and about the same time two of the cast-iron columns fractured, one round the base and the other across the foot (figs. 1 and 2). The cracks in the wall were repaired from the inside, but the tank was never tight, and it gradually began to leak more and more until the water would only stand at half its full depth. When consulted in the matter, the writer inspected the tank and found that it was $7\frac{3}{8}$ in. out of level, with a clearly-defined tilt in one direction, and that there were now five bad vertical cracks in the tank wall; two being the old ones which had re-opened (figs. 3, 4, and 5). These cracks varied respectively from $\frac{1}{2}$ in. to 2 in. in width; and since no assurance could be obtained that subsidence or the effect of underground workings could be said to have ceased, and in view of the unsatisfactory result of the previous repairs, it was decided to abandon the

Fig. 4.

holder and tank, and to construct a new spiral holder in a steel tank on a reinforced concrete raft on an adjoining site, which was further removed from the influence of pit workings.

A masonry tank 103 ft. in diameter by 22 ft. deep, with puddle backing and flat puddled bottom, constructed about 1858, and entirely sunk in the ground, had originally contained a two-lift column-guided holder having a capacity of a little over 250,000 c.ft. of gas. At a considerably later date, a third lift, rope-guided, was added, and about sixteen years ago there was a further addition made of a fourth lift, also rope-guided, bringing up the capacity of the holder to about 500,000 c.ft.

Some twelve months after the fourth lift had been added, a slight loss of water—about $\frac{1}{2}$ in., or 2000 gallons, per 24 hours—was noticed; and as attention had been drawn to cracks in buildings and reports of subsidences in the neighbourhood, the level of the tank was ascertained, and it was found that it had a tilt of about $3\frac{1}{4}$ in. Fifteen months later the loss had increased to 3 in., or 13,000 gallons, per 24 hours; and it was then decided to adopt the expedient of dropping mill-dust into the water between the tank wall and the holder; the idea, of course, being that the mill-dust, as it soaked, would sink and be drawn gradually by the current of water to the crack or cracks in the tank, and thus stop, or at any rate reduce, the leakage. It was known that this method had been adopted in several places with considerable success; but in the case in point, though some 8 tons in all of mill-dust were so used, no benefit was derived; in fact, the leakage continued to get worse. There was therefore nothing left but to land the holder and empty the tank. Before this was quite empty, the pump was stopped, and an inspection of the interior was made from a raft, with the object of ascertaining whether or not a current of water could be discovered leading to the seat of the trouble. Corks and small paper boats were distributed over the surface of the water, and left there for a week-end; but no definite information was thus obtained. Though the head of water was now greatly reduced, the leakage continued at the rate of about 1 in. per day until the tank became completely empty; and, owing to the fact that the bottom was covered by the mill-dust which had been dropped into the tank at an earlier stage, no clue could be obtained as to where the leakage was

Fig. 5.

taking place. The bottom was cleared, and the lifts of the holder raised so that the tank wall could be examined; but, beyond a few fine cracks, there was nothing seriously wrong with it. These cracks were subsequently grouted with cement, and pointed-up. The puddle on the bottom of the tank was examined, and it was found that a considerable portion of it had lost its nature, being short and sandy. On excavating in the bottom, the puddle was found to be about 2 ft. thick, and to be lying in one place on a bed of sandy soil, and in another on running sand into which a rod could be driven-down 3 or 4 ft. without effort. Further investigation showed that several of the rest blocks, of which there were fifteen (fig. 6), had tilted forward towards the centre of the tank, and had broken-away from their connection to the tank wall—due, no doubt, to the additional weight of the two extra lifts which had been added to the holder, and especially to that of the fourth lift acting on a bracket extension of the original block. It was now fairly evident that leakage from the tank had occurred where these rest blocks had failed, allowing the water to percolate through the puddle to the sandy bed below.

It was decided to remove all the old rest blocks and also the top 12 in. of the existing puddle, and to form a continuous reinforced concrete toe to the wall, 7 ft. wide by 13 in. thick,

laid on the lower half of the old puddle which had been previously cut, turned, and rammed to a depth of 11 in. On this toe were constructed 24 new rest blocks in brickwork, 5 ft. 6 in. long by 18 in. wide, and now long enough to take the four lifts of the holder. On top of each of these blocks were laid two 5-in. by 1-in. flats, side by side, bedded in cement. The old puddle removed was re-laid over the bottom of the tank in the form of a flat cone of about 2 ft. rise, and on it was placed a layer of entirely new first-class puddle 12 in. thick, covering the whole of the bottom and finishing to the upper level of the concrete toe. This done, the tank was refilled with water and was found tight, in which condition it has since remained—a period now extending to about thirteen years.

In considering the above case, there is no evidence that subsidence was directly responsible for the damage; but there is the tilt of the tank for which to account, and also the fact of the presence of cracks, obviously due to ground movement, in surrounding buildings.

The last case is by far the most serious one with which the writer has been connected, and concerns a tank (fig. 7), 153 ft. 3 in. in diameter by 32 ft. deep, constructed thirty years ago. It is a brick tank and, except for the top 6 ft., which is supported by earthwork, is entirely sunk in the ground, which consists of boulder-clay. The back of the tank is puddled, and the truncated coned bottom is formed in the natural clay, which had merely been trimmed after excavation. It contains a three-lift frame-guided holder with untrussed crown and timber rest

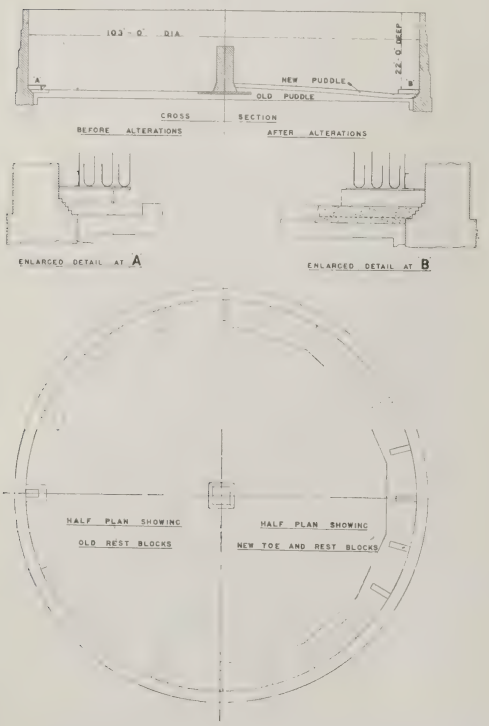

Fig. 6.

framing fixed in the tank. The capacity of the holder is $1\frac{1}{2}$ million c.ft.

Some twelve or thirteen years ago the appearance of sundry small cracks was noticed in buildings in the works adjacent to this tank. Test pats formed of a mixture of cement and plaster of Paris were applied to them, which on inspection from time to time indicated that some serious subsidence was developing. A general inspection of the works was made, and it was then found that this tank was $2\frac{3}{4}$ in. out of level. Two years after the discovery of the cracks, the event, of which the following is a chronicle, took place.

The gasholder attendant early one morning noticed that gas was blowing from under the bottom curb before the holder was quite full. On making an inspection, he found that the water in the tank was down about 3 ft. below the coping. He thereupon turned on a hose-pipe from a neighbouring fire hydrant, and left the water running into the tank. Shortly after, with a foreman, he again visited the tank, and found that, in spite of the hose-pipe running full, the tank was still losing water.

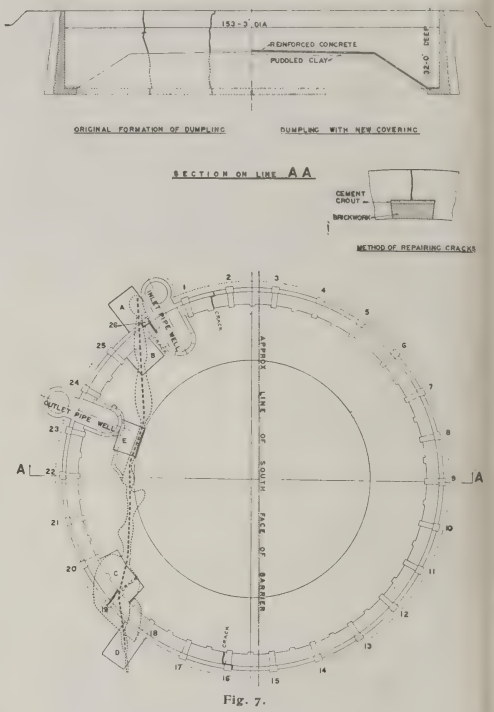

Fig. 7.

It was now recognized that the situation was serious; and the holder being practically full at the time, as much as possible of the gas was transferred to other holders until they were full. Some two hours after the loss of water was first noticed, the level had fallen 4 ft. 6 in. below the coping; and it was then decided, as the wind was favourable, that the gas should be liberated from the holder by loosening the manhole covers on the crown. Shortly after this was done, the bottom lift grounded and the second and top lifts dropped 4 ft.—fortunately without serious result. Meanwhile the release of the gas was expedited; but unfortunately the wind had now changed, and was blowing the escaping gas in the direction of some cottages close by. It was therefore considered advisable to turn-out the tenants, and to extinguish all their fires and lights. By this time the second lift had grounded, leaving the top lift a drop of 7 ft. before it found the water. In doing so, it threw up a fringe of water round its periphery to a height of about 25 ft. (fig. 8). It was an awe-inspiring spectacle, but, to the great relief of everyone concerned, the drop occasioned no visible damage, nor was any material damage found afterwards. The loss of water went on at a decreasing speed owing to the reducing head in the tank, until thirty hours after it was first discovered the tank was completely empty—during which time $2\frac{1}{2}$ million gallons of water had disappeared into the earth.

As soon as possible, examination of the tank wall was made, and three vertical cracks were discovered between standards 1 and 2, at standard 26, and at standard 16, running from top to bottom—that at standard 26 being the largest (figs. 9 and 10). The cracks varied respectively from $\frac{1}{16}$ in. to $\frac{1}{2}$ in. in

Fig. 8.—Showing Fringe of Water round Holder.

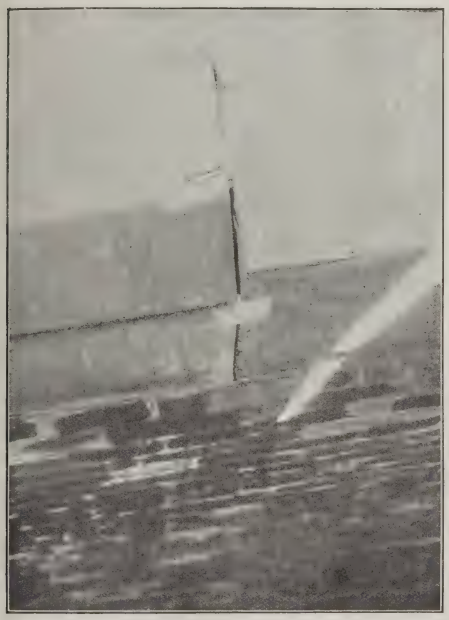

Fig. 9.—Crack in Tank Wall.

width. There was also a fourth crack at standard 19 running from the bottom to half-way up. All the cracks became somewhat larger as they approached the bottom. They also ran through the internal brick toe of the wall, which is 5 ft. wide and 2 ft. 6 in. thick, where they became wider still; and in the worst case, that at standard 26, the crack was $1\frac{1}{4}$ in. open at its maximum width (fig. 11). No fissure could be found in the dumpling; but the clay on its surface was in an extremely plastic condition. The conclusion was therefore come to that, if any fissure had developed, it might have closed again as soon as the water had run out. Of the test pats re-applied to cracks in the neighbouring buildings a few months earlier, it was found that 50 p.ct. of them had broken.

On removing the clay in the bottom of the tank in front of the toe of the wall at the points where the cracks occurred, an aperture was found at standard 26, which, when followed-up,

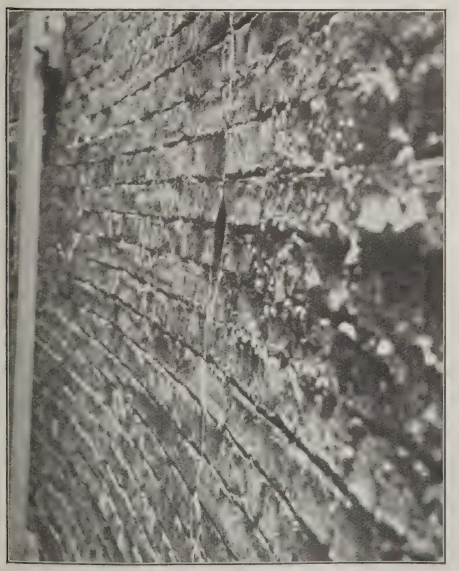

Fig. 10.—Crack in Tank Wall.

apparently led to some considerable cavity behind the wall, since when a hose-pipe was turned into this opening the water ran away as fast as it could be put in, and a sound was heard of water falling into some subterranean chamber. It was now evident that it was at this point that the bulk of the water had escaped; and the excavation was carried further, exposing a cavity leading from the inside of the tank back under the tank wall, a distance of about 18 ft. (fig. 12). It was therefore decided to sink an exploration shaft A immediately outside the tank wall down to the cavity, the floor of which was found to be 44 ft. below the coping. On exploring the cavity, it was discovered that it communicated with a second cavity running back again under the tank wall and under the dumpling, a distance of about 20 ft. This cavity was 4 ft. to 5 ft. wide and 3 ft. to 4 ft. high, and dipped rapidly towards its farther end. Another shaft B was sunk inside the tank immediately over this second cavity, opening it up. When this was done, an opening was found leading into yet another cavity extending under the dumpling for a distance of some 24 ft. It was 5 ft. or 6 ft. wide and of uncertain height, possibly 8 ft. or 10 ft. The floor was found to be limestone marl, and was heaped-up with a dome-shaped mass of clay which had fallen from its roof. It was now apparent from these explorations that the leakage was due to the water

Fig. 11.—Crack in Toe of Wall.

forcing itself through the crack in the toe of the wall at standard 26, and boring its way through the boulder clay to a fissure in the marl beneath, and that the rush of water had washed-out the softer portions of the clay and carried them away, thus forming the cavities described. A bore hole was sunk in the bottom of shaft A, when it was found that the boulder-clay extended to a depth of 54 ft. from the tank coping, below which lay the marl; limestone being struck at 81 ft. 6 in. Water was found standing at 69 ft. Another bore hole was sunk on the opposite side of the tank at a convenient point some little distance away, which showed boulder-clay to a depth of 53 ft., when marl was struck. The bore hole was continued to a total depth of 95 ft., but still showed marl; and water was found at 74 ft.

It was decided to drift through from one cavity to another, removing all the loose clay, and to put a stopper of concrete in the far outlet of the third cavity where it had reached the marl, then to fill up the whole of the cavities, drifts, and shaft B with weak concrete. The process was analogous to that of a dentist at work on a decayed tooth, when he first drills away the unsound material and then fills-in with a suitable stopping. The clay surface of the dumpling was removed over the whole of its area to a depth of 12 in., worked up as puddle, and replaced. The cracks in the toe of the wall were cut-out as far as necessary, grouted up with cement, and the brickwork made good. The vertical cracks in the wall were treated in the following manner (fig. 7). The wall was cut out for a distance of 6 in. or 8 in. on each side of the crack, and to a depth of 11 in., thus forming a more or less vertical chase about 14 in. wide by 11 in. deep. The front of the chase was filled up with 9-in. brickwork in cement; the joint with the old work being dove-tailed, leaving a cavity 2 in. wide at the back of the new brickwork. This cavity was run-in solid with

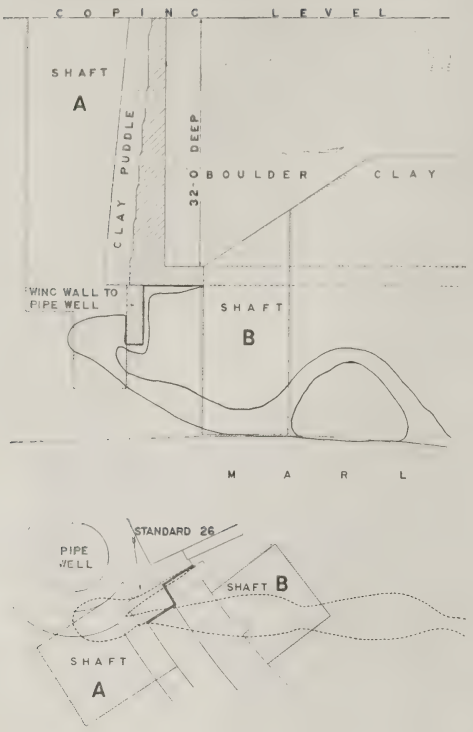

Fig. 12.

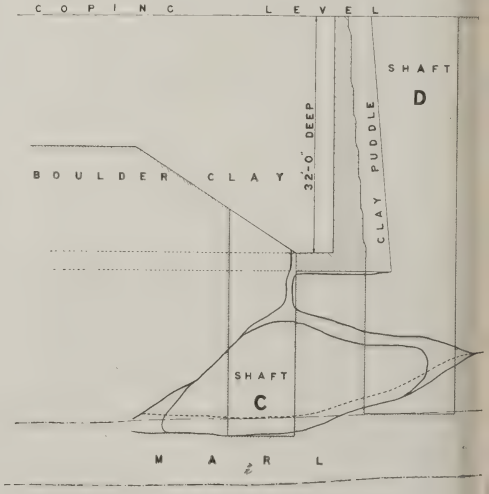
cement grout as the work went on. In the case of the worst crack—that at standard 26, and which was accessible at the back from the shaft A—cramps of flat steel, 3 in. by ¾ in., were built into the wall at vertical heights of about 3 ft. 6 in. The excavation under the wall and the bottom of shaft A was filled-in solid with strong concrete, the puddle backing was replaced, and the ground behind it filled-in and made good.

After these repairs, which occupied six months, were completed, the tank was filled with water up to within 2 ft. of the coping, when it was discovered that there was a slight leak amounting to about 1¼ in. in two hours. During the next four hours the loss increased to 16 in.; and within 36 hours of the filling, the whole of the contents of the tank had again disappeared. While the water was falling, small corks were dropped into the tank at various points, with a view to obtaining information as to what had occurred. The interior was inspected, and there was no difficulty in locating the seat of the trouble, which now appeared at standard 19 (fig. 13), and took the form of a fissure 3 ft. 3 in. by 4 in. wide in the clay bottom of the tank close up against the toe of the wall where it had been cracked. There were also two smaller holes in the bottom a few feet away from the fissure, each of which communicated with the larger opening. On following-up the fissure, it was found to communicate with a cavity very similar in character to those at standard 26, but larger, as it measured approximately 13 ft. in length by 7 ft. in width. The floor of this cavity was about 44 ft. below the coping. It apparently extended still further at a lower level, running both outwards under the tank wall and inwards under the dumpling; and it was now clear that the cavity lay more or less on the line joining up the cracks in the wall at standards 19 and 26, and that—a matter of very great interest—this line was approximately parallel to what had been ascertained to be one face of the barrier between two adjacent collieries. A shaft C was sunk inside the tank over the cavity, and carried down for a depth of 57 ft. below the coping into the marl, when a distinct fissure was discovered, into which an iron bar could easily be pushed down 4 or 5 ft. This fissure took approximately the same line as that of the cavity. A fourth shaft D was sunk outside the tank wall, and a drift carried through under the wall to shaft C. All loose clay was removed, and, as in the previous case, the wall was underpinned with strong concrete, and the cavities and shaft C filled in with a weaker mixture. In shaft D the puddle backing was replaced, and the ground filled-in solid behind.

A curious circumstance was noticed when excavating at the bottom of shaft D. The entrance to a small fissure in the clay was discovered; and on inserting a lighted candle to obtain a view of the interior, the flame became extinguished, though no draught was perceptible. This was due to the presence of CO_2 gas—a fact which was verified in the laboratory. The test was repeated on other occasions with the same result. In time, the supply of CO_2 exhausted itself. At a later period, but from another small fissure, a hissing sound was heard, which proved to be air under a slight pressure sufficient to blow out a candle. The following day, instead of the pressure there was an indrawing of the air which sucked-in the candle flame. On later occasions it was found there was sometimes a pressure and sometimes a suction of air at the orifice; but no exact record was kept of the periods of alternation. One conclusion drawn from these observations was that the changes in the flow of air might be due to the ventilating arrangements in the pit below. While exploring at the bottom of this shaft, one of the corks, which had been previously thrown into the tank while the water was falling, was discovered embedded in the soft clay at one side of the cavity.

After the repairs were completed—and they took about ten weeks to carry out—the tank was gradually filled with water for the second time, until a level of 16 in. below the coping was reached, when the water was shut-off. It was naturally hoped that the tank would now be found tight, but measurements showed that there was an average loss over the first three days of about ⅜ in. per day. Next day the loss had increased to 22 in., and the day after the water was down between 13 ft. and 14 ft. below the coping, and it continued to run out until there was only 5 ft. depth of water left in the tank. On inspecting the interior of the tank, an oval hole approximately 3 ft. long by 18 in. wide was discovered in the sloping side of the dumpling (fig. 14) leading more or less downwards into the interior of the ground; and the water was seen to be just trickling over the lip of the hole. This hole apparently led in a direction which would pick-up the line of fissure ascertained from the previous explorations. A shaft E was sunk in the dumpling at a point where it was expected the hole joined the fissure; and a cavity was found which on being followed led, as had been anticipated, in either direction in the line of the fissure in the marl. Drifts were carried in both directions—that is, to standards 26 and 19—until the concrete stoppings previously mentioned were picked-up. These drifts and the shaft were then filled-up with concrete as before.

It was now considered that the time had arrived for the



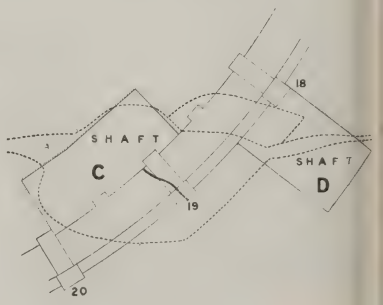


Fig. 13.

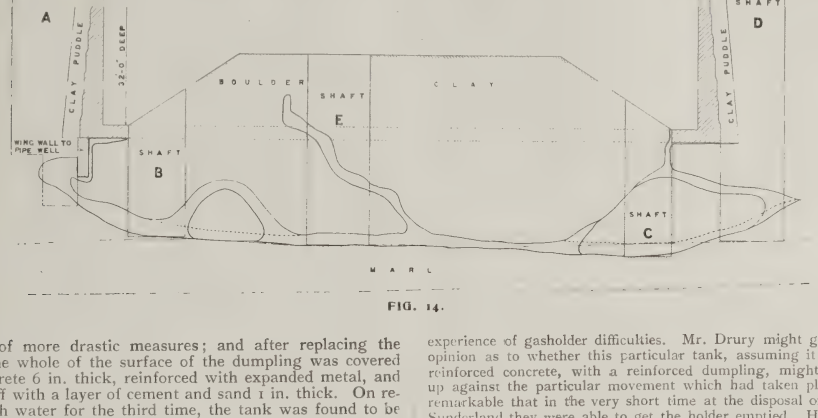

FIG. 14.

adoption of more drastic measures; and after replacing the puddle, the whole of the surface of the dumpling was covered with concrete 6 in. thick, reinforced with expanded metal, and finished-off with a layer of cement and sand 1 in. thick. On refilling with water for the third time, the tank was found to be bottle-tight; and after nine years it still remains so.

From the plan (fig. 7) it will be evident that the cause of the accident to the tank was the breaking of its back through unequal subsidence, due to the fact that one face of the barrier between two neighbouring collieries ran diametrically under it. This unequal subsidence had produced a fissure in the limestone marl, and had probably disturbed the overlying boulder-clay, thus permitting the water in the tank, under its full head, to bore its way through the clay, and disappear in the marl.

Discussion.

The CHAIRMAN, in opening the discussion, said Mr. Drury's paper was one of those contributions upon which the ordinary form of discussion was hardly possible; but it was a matter of interesting experience which was distinctly informative to them as engineers. It was a very valuable thing to have such an experience recorded in such detail for the guidance of any who might on future occasions have similar trouble to face. The last example of the author's difficulties was so outstanding as to overshadow the rest. They were indebted to him for recording it so carefully and describing it so fully.

Mr. W. W. ATLEY (Stockton) congratulated Mr. Drury on the way he had tackled the gasholder tanks. The last case described was a most extraordinary one, and he (the speaker) was very glad that he was not the responsible engineer who had had to undertake the work. Mr. Drury must be congratulated on the excellent way in which he carried out the repairs. He would like to ask Mr. Drury what he did with the holder during the period he was dealing with the repairs.

Mr. F. H. ROBINSON (Harrogate) asked whether the tanks were constructed before the colliery workings approached them. If they were constructed after the workings came near the tanks, then it seemed to suggest that the design was weak, in view of the local conditions.

Mr. A. C. HOVEY (London) said the general public possibly regarded gas manufacture as a mysterious process, and the life of a gas engineer as of a somewhat prosaic character. Mr. Drury's experiences in connection with gasholder tanks, which he had narrated to them that day, proved, however, that there were frequently both romance and adventure in this occupation. He wished to associate himself with the expressions of appreciation from other speakers of the courage and persevering skill which Mr. Drury had exhibited in dealing with important and difficult problems. The success which ultimately attended his undaunted efforts in the renovation of the large gasholder tank was particularly commendable, and the description was a valuable contribution to the proceedings of the Association, and worthy of the notice of gas and civil engineers throughout the world. In designing a gasholder, and concrete tank of similar size, he (Mr. Hovey) had arranged a concrete covering over the surface of the tank dumpling, though the subsoil was boulder clay; and he suggested that, if such covering had been incorporated with the toe of the wall of the Sunderland tank, the water would not have leaked out. He presumed that as boulder clay was such suitable material in which to construct a gasholder tank, the concrete covering of the dumpling had been omitted as a matter of economy. Where mining operations were in the neighbourhood, and the subsoil within the area did not vary greatly across it, a steel tank was probably the best, though there was a limit to the size. Mr. Drury had doubtless carefully examined the law in relation to the prevention of a colliery company approaching underground the site of a gas-works, and the liability involved. Any information on this would be interesting.

Mr. F. P. TARRATT (Newcastle) said he had had an opportunity of inspecting the particular tank referred to, and of going down the shafts. The conditions were not altogether pleasing; and one never knew what difficulties one was up against. So far as the construction of the tank was concerned, it was one of the best gasholders he had seen. The trouble arose through subsidence. The systematic way in which Mr. Drury persevered in tracking the source of the trouble until he eventually discovered the third leakage on the dumpling was most praiseworthy. It was a great anxiety to Mr. Drury, for he was without the use of the gasholder for 2½ years.

Mr. F. C. WILLIS (Tynemouth) said Mr. Drury had had a unique experience of gasholder difficulties. Mr. Drury might give them his opinion as to whether this particular tank, assuming it had been of reinforced concrete, with a reinforced dumpling, might have stood up against the particular movement which had taken place. It was remarkable that in the very short time at the disposal of the staff at Sunderland they were able to get the holder emptied. He would like to ask if there was any apparent strain in the standards or the diagonal bracings at standards 19 and 26. The circumstances seemed to point to the great importance of avoiding the erection of holders of that size too close to other holders. When Mr. Drury referred to the loss of water—something like 2¾ million gallons disappearing in 30 hours—it occurred to him (the speaker) that surely there must have been evidence of this water in another place. Mr. Drury was to be congratulated on his determination, amid great trials, and upon the successful way in which he overcame his difficulties.

Mr. DRURY, replying to the discussion, said it was very flattering to find that his paper had met with so kind a reception. He had not been responsible for the construction of the tanks, except one; they were built before he had anything to do with them. Though he had not named the locations of any of the tanks, it was obvious that the larger one belonged to Sunderland. He would like to say that he had the great advantage, in dealing with the collapse of the tank, of having an eminent Engineer as one of his Directors; and to him he (Mr. Drury) wished to acknowledge his obligation for the great assistance and support he received in carrying out what was an extremely heavy job. He had been asked what he did while the holder was under repair. He had done nothing. They left it on the rest blocks. As to the nearness of colliery workings, in some cases the tanks were constructed after colliery workings, and sometimes before the workings got near. The colliery workings were in the neighbourhood; but no doubt they gradually approached nearer the tanks until the subsidence occurred. A reference had been made to the romance of the gas engineer's life. It certainly was an interesting occupation. One found new problems every day; but he would not like to look forward to an experience similar to that which he had described in his paper. As to how far the law allowed colliery workings to approach gasholders, it was not for him to define the law at that juncture. There was a Parliamentary Inquiry being held regarding the effect of subsidence on property generally; and it had been sitting for about eighteen months. It would be best to await their report. The tanks were built partly on the barrier or boundary of two collieries, and the subsidence was more general in the case of the large tank. The boulder clay was bottle-dry, and thus the engineer would conclude he was quite safe. There was no apparent strain on standards Nos. 19 and 26. As to the steel tank to be relevelled on its foundations, this was not yet an accomplished fact, but they did not anticipate any serious trouble. Respecting the loss of 2½ million gallons of water, they made inquiries in all directions, to try to trace it; but they never heard of an influx anywhere. They might assume that it caused some disturbance somewhere, but they never heard of it.

Mr. W. M. GALLEWAY (Whitby) followed with a paper on "Income-Tax Allowances for Wear and Tear of Gas-Works Plant." [This is held-over until next week.] Thereafter

Mr. RIDLEY moved a vote of thanks to the readers of the papers. This was seconded by Mr. I. SPENCER (Seaham Harbour), and supported by the PRESIDENT.

OFFICERS FOR THE ENSUING YEAR.

The election of officers for the ensuing year resulted as follows:

President.—Mr. W. W. Atley, Stockton.

Vice-President.—Mr. Herbert Lees, Hexham.

Committee.—Mr. D. Currie, South Shields; Mr. C. Dru Drury, Sunderland; and Mr. F. P. Tarratt, Newcastle.

Hon. Secretary and Treasurer (re-elected).—Mr. Norman S. Cox, Sunderland.

Hon. Auditor (re-elected).—Mr. Charles H. Armstrong, Newcastle.

It was agreed, on the invitation of Mr. Atley, to hold the October meeting of the Association at Stockton.

Votes of thanks were accorded to the retiring President, the Committee, the Secretary and Treasurer, and the Auditor.

"B.C.G.A." NORTH WALES AND CHESHIRE DISTRICT CONFERENCE.

A GOOD GATHERING AT CHESTER.

It was a wise decision to select the beautiful City of Chester, which possesses so many advantages for such a gathering—high among which must be placed its progressive Gas Company—for the purpose of a British Commercial Gas Association North Wales and Cheshire District Conference. This was held last Wednesday, when a full programme attracted a good attendance of neighbouring gas men, as well as, at the afternoon session, of the general public. To those acquainted with the lines on which the Chester United Gas Company is worked, it is unnecessary to say that nothing was left undone to make the conference a success. The President was Alderman Sir John M. Frost, J.P. (the Chairman of the Company); and both he and Mr. F. A. Pye (the Secretary and General Manager) did everything in their power to assure a pleasant and profitable day. The Mayor (Alderman David Lythall Hewitt, J.P.) also devoted much of his busy day to the meeting.

The conference was held in the Assembly Rooms, Newgate Street; and at the opening of the proceedings the President introduced the Mayor.

The Mayor offered the delegates a hearty welcome to the ancient and beautiful city, and in his remarks gave expression to broad-minded views, which were much appreciated, on the subject of gas and electricity. While naturally proud of the city's electrical installation, he said he could not help being struck by the soundness of the present achievements and future possibilities of gas.

The President's Remarks.

Sir John Frost, having thanked the Mayor for his welcome, said that the easy-going character which was sometimes associated with cathedral cities did not apply to Chester. So long ago as in 1817 a company was formed in Chester to supply gas for illumination, and in 1818 a part of the centre of the city was first lighted with gas. Toll bridges were "freed" quite early in Chester. Electric light was introduced by municipal enterprise in 1897; electric trams followed soon afterwards; so, broadly speaking, ancient Chester had placed itself well in the van, rather than the rearguard, of modern developments and improvements. Gas had been supplied continuously since 1818; and his Company were among the original ones who assisted in the inauguration of the Association whose development they had met that day to encourage. The North Wales district was more difficult to organize than compact areas like the Midlands or Lancashire and Yorkshire; and they were therefore pleased to comply with the request to hold this conference in Chester, and cover a wider area, so that a larger programme could be arranged. The industry they represented was one of those of which they were justly proud. It was based on coal—the nation's most valuable asset—and in their methods none of the innumerable valuable constituents was destroyed or wasted. With the exception of modern coke-oven plants, there was no other method of dealing with coal so advantageously from the point of view of economy of the country's resources. This being the case, it was the more justifiable to organize a competent body to bring the advantages of gas systematically and insistently before the public. The British Commercial Gas Association was formed for this purpose, and they wanted every undertaking in the country—municipally or privately owned—to be affiliated with it. The smaller the works, the greater the relative value, because the advice given by the officials of the Association was that given by men of far greater and wider experience than such small works could hope to command with their limited financial means. The industry's general organization was on sound lines.

He would like for a moment to refer to the present industrial situation, which they all knew was deplorable. It was the aftermath of the war, and also the aftermath of post-war agreements and disagreements. But this was not all. During the war attention was absorbed by the war itself; and, as it pursued its weary course, there developed a tendency to forget the trend of industrial development immediately prior to the war. The fact was that this country's prosperity was built-up in the early part of the nineteenth century by the pioneer efforts of British manufacturers. Following this beginning, they knew that in a large degree nearly all countries came to this one to learn how to manufacture; and the competition in trade was being felt most seriously in this country, although in a varying degree, in pre-war days. Now the people of this country were in the position that, (1) being British, they wanted to pay their debts and were doing so; (2) owing to the waste of war the world demand for goods was reduced, on account of its inability to pay for them; and (3) other countries, equally well equipped with machinery, were in a position to quote for what demand existed at a lower price than that at which this country could economically produce, because they were not paying their debts, and labourers took lower wages and worked longer hours. The result of all this was naturally a feeling of disquietude and unrest; and proposals of all kinds were being made. There was some suggestion afloat—with what authority he did not know—to the effect that some £50,000,000 should be voted to the development of electrical super-power stations. That was one of the principal panaceas to encourage industry at the present moment, and, at the same time, to bring such amenities to life in the agricultural districts as would not only check the old-time constant flow of labour from agricultural to urban districts, but would actually attract the unemployed artisan into agriculture. Well, if such an ideal were feasible, he asked how far would £50,000,000 go. In saying this, he did not wish to deprecate the use of electricity in many branches of private and commercial life. He believed they would agree with him that, as in the past so in the future, private enterprise had got to remain the sound source of national prosperity. The gas industry in this country had developed to the highest efficiency in the world, without State aid; and so had all the other foundation industries of the country.

Mr. J. H. Crowther (Wallasey) proposed a vote of thanks to the Mayor and the President for their remarks. Referring to the competition of electricity, he said that, with a charge of (say) 6d. a unit for lighting and 1d. for cooking, people thought there must be a bargain in the latter; whereas, as a matter of fact, those present knew that what was being offered by electricity for 1d. for cooking could be supplied by gas at one-third of a penny. Both industries should be worked on commercial lines. As to the future of gas, companies had advantages which municipalities did not possess. Gas companies could extend their operations over a wider area; and he thought that, as time went on, this would be done more and more. Smaller works would be united with bigger ones, with beneficial results alike to the consumers and to those who had invested their money in the undertakings.

Mr. G. S. Frith (Runcorn), seconding, remarked that he happened to live in a district where there was a super-power station, and in a few weeks he believed they would be connected-up with 110 miles of continuous overhead wires; but with all this competition, and current down to 4d., the gas undertaking was still extending its business. He did not see that they need be afraid of healthy competition. With care and perseverance, he believed the gas consumption per house could be trebled. The name of Frost had always in his mind been coupled with the Chester Gas Company, and he hoped it would remain so for many years to come.

The President, in acknowledgment, agreed that there were great uses for both electricity and gas; and the two should work harmoniously together. So far as his Company were concerned, the output of gas grew year by year, and he saw no reason to anticipate any alteration in this respect.

The Association.

Mr. W. M. Mason (the Manager of the "B.C.G.A.") then made a statement with regard to the work and policy of the Association, now and in the future. He felt sure all present would agree with him that one of the most useful things the Association had accomplished for the gas industry was to provide a platform for men such as they had with them that day. It was an added strength to the whole gas industry that they got administrators like Sir John Frost and public men like the Mayor of Chester to co-operate with them, not in a controversial sense, but in a harmonious way. Some people might wonder what was the use of having so many meetings; but the one thing that had to be remembered was that, while some of them knew the story from beginning to end, there were others who had still to learn a good deal about the matter. Really the main object of the Association was the education of the public by propaganda; the two great obstacles to progress that had to be overcome were prejudice and ignorance. One of the biggest things the Association had done was to convert the medical profession very largely to a favourable view of gas as a hygienic fuel. This was an example of overcoming prejudice. For the removal of ignorance, they made extensive use of the Press. The Association now embraced 92 p.ct. of the make of gas; but on a numerical basis, the 800 undertakings who subscribed represented only about 50 p.ct., though this included practically all the large concerns. Undertakings who were slack at present in this respect would suffer for it in the future. If the work of the National Association in letting the country know what the industry stood for and what it could do ceased to-morrow, the effect might not be immediately notice-

able, but some day it would be found that gas undertakings were being left behind. They must recognize the necessity for educating the modern public to the advantages of gas. It paid to advertise, if the product was right, if the service was right, and if the advertising was right. This was proved by the way in which the gas industry was going ahead, in spite of strenuous competition.

NATIONAL ECONOMY IN THE USE OF COAL.

Mr. Owen Evans (Engineer and Manager of the Wrexham Gas Company) read a paper in which he dealt with the vital question of coal conservation. It was pointed out by him that the past industrial and commercial greatness of Great Britain has been mostly due to the possession of an abundant supply of cheap coal; and her immediate and future prosperity will undoubtedly continue to depend upon this our great industrial asset. Careful conservation is absolutely essential. The Coal Conservation Committee presided over by Lord Haldane, who reported in 1918, favoured the erection of large central or "super" stations for the generation of electricity, using coal-fired steam turbines, and claimed, by comparing such a scheme with the wastefulness of the small isolated steam engines in very common use, that the coal consumption for power-production purposes could be reduced from 5 lbs. to 1 lb. per H.P.-hour, and thus effect a saving of 55 million tons of coal per annum for present power requirements. If this were true, nothing could be more desirable; but unfortunately the Committee's findings were based upon many fallacious assumptions, which have been dealt with fully by Sir Dugald Clerk, F.R.S.

The facts revealed by Sir Dugald Clerk, indeed, put a very different complexion upon the matter. They showed that, while the generation of electricity at super-stations, with the estimated, but as yet unachieved, consumption of only 1 lb. of coal per electrical horse-power, would effect a marked economy in coal consumption in comparison with that ($2\frac{1}{2}$ lbs. per E.H.P.) at the average existing generating stations, and while it would therefore be a great advantage that all present and additional requirements of electrical energy for lighting or power purposes should be generated by plant so comparatively economical in coal consumption, the use as a source of heat of electrical energy generated from even such a reduced consumption of coal as that promised would be a grossly wasteful method of using our coal supplies. Sir Dugald gave authoritative—and startling—figures showing that, out of every 100 heat units contained in the coal consumed in the average generating station in this country, over 92 are absolutely lost to the community, and less than 8 reach the consumer as electrical energy; that in the best station to-day the waste is 88 p.ct.; and that in the proposed super-stations, if the hitherto unattained economy promised by the experts is reached, the waste will still be over 80 out of every 100 units.

If coal were used solely for power and lighting, a good case could be made out for its substitution by electricity, as electricity is an efficient and convenient means of transmitting power and producing light, and it is, of course, indispensable for electric railways. It must be remembered, however, that more than one-half of the coal consumed in this country is used for the production of heat; and the proposal to substitute electricity for coal for this purpose can only be accomplished at the cost of an enormous increase in the quantity of coal used. The only sure way to the conservation of coal lies in its scientific treatment; and in this respect the gas industry has always led the way.

Although the use of gas is increasing to an enormous extent for heating and cooking for domestic purposes, it is estimated that about 40 million tons of coal per annum are still supplied for these purposes in the raw state; and one may consider the result of substituting gas, which has now become a practical proposition. The average efficiency of gas in actual use for the customary domestic duties is well over 50 p.ct.; and if all the coal at present consumed for domestic purposes was carbonized at the gas-works, no more coal would have to be used, and there would be over 20 million tons of coke to spare, which could be utilized with efficiency, in displacement of coal, for various industrial purposes, for railway locomotives, and for the generation of electricity, &c. There would also be an enormous additional supply of the other bye-products. Or, alternatively, such is the flexibility of the gas-works method, the whole of the extra coke and tar produced could be gasified, and the coal used at the gas-works would be proportionately reduced. On the other hand, if the coal used for domestic purposes is to be substituted by electricity, as proposed under the super-station scheme, the quantity of coal required would be increased threefold—*i.e.*, to the enormous quantity of 120 million tons per annum.

In the industrial world the position is rather different, and the larger proportion of the coal used is for power purposes; but at the same time it must be borne in mind that many industries require a large quantity of heat, and a solution of the power problem from the point of view of coal conservation does not by any means solve the heating problem. It is estimated that 60 to 70 million tons of coal are employed annually for various industrial purposes; and if this was all used for the production of power, the claim that electricity could be substituted at a lower coal consumption would have some foundation. A still stronger claim could, however, be put forward on behalf of internal combustion engines, as the efficiency of such engines is exceedingly high, and the great advantage of gas power is that small units, such as 50 B.H.P., give efficiencies quite as high as those of the larger units of gas and super units of electricity.

Mr. David Brownlie estimates that, of the total quantity of coal used, from 20 to 30 p.ct.—probably some 20 million tons—is consumed annually in boiler furnaces, &c., to raise steam and provide heat for various manufacturing processes other than power. Many industries requiring both heat and power make use, generally in a most economical manner, of the waste steam of their steam-generating plants, and the exhaust gases of internal combustion engines, to provide the necessary heat. Great possibilities exist in this direction, and further developments on similar lines would be the means of a substantial saving in coal.

It is, the author went on, difficult to see upon what grounds the claim has been made that the use of electricity solely for all industrial purposes will assist in the conservation of coal; in fact, everything points to the contrary, and in the event of such a happening, there can be little doubt that it would result in the quantity of coal used being very considerably increased.

The concluding portion of the paper dealt with coke. Mr. Evans said that the use of coke for domestic purposes has not advanced as rapidly as desired; but if every effort is made by the gas undertakings of the country to draw public attention to its general usefulness and economy, a large quantity can be disposed of, to the interests of the consumers, the gas undertakings, and coal conservation.

Discussion.

The President voiced the thanks of the meeting to Mr. Mason and Mr. Evans.

Mr. J. Smith (Colwyn Bay) said the "B.C.G.A." were doing excellent national service. It needed driving home that, in the case of electricity supply, 92 p.ct. of the energy in the coal was wasted, and only 8 p.ct. could be delivered to the consumer. He pointed out that the crude oils derivable from tar offered great opportunities for Diesel engines. Some of his friends were obtaining excellent results in this way. Mr. Evans had made out a good case. They could generate a large percentage of the electricity at present consumed in the country by the products remaining after they had given the public a supply of good and cheap gas; and in view of the conservation of the coal resources, this was one of the points that they, as gas engineers and as representatives of the community, ought always to keep well before the public.

Mr. Crowther, referring to the work of the "B.C.G.A.," said he wondered sometimes whether they would not be justified in making comparisons with electricity—in saying in some of their advertisements what really could be done by the two competitors, gas and electricity, in different classes of work. They stated what could be done by gas, and it was a good story; but many people did not know what could not be done by electricity in the way of heating. As to Mr. Evans's paper, a gas-engine for super-power stations was not in the market. People were not going to take out small-sized steam engines and put in gas engines. He did not see how they could look forward to any good business from electricity works in the way of coke supply, when such works could buy slack containing practically the same B.Th.U. as did the coke. They would have to look more to the domestic market for sales of coke, if exports continued to fade away, and not expect electricity stations to purchase it.

Mr. Mason replied that Mr. Crowther's suggestion had been discussed very fully and very frequently by the "B.C.G.A." Executive. There were two main reasons why the Association had never had anything to do with controversial publicity. The first was that it was not good business; and the second was that so many municipalities who possessed both gas and electricity undertakings were members of the Association.

Mr. Evans said his argument was that if gas engines were used more for the generation of electricity, coal conservation would result. With regard to coke for boiler firing, there were places where slack was not easily procurable, and coke was being employed very economically. There were numerous instances of coke breeze and coal being used successfully on what was known as the "Sandwich" system.

Mr. Pye, speaking as Chairman of the North Wales Commercial Section, said the trouble in that district was that, owing to the scattered nature of the area, they did not get the support of some of the small undertakings. Such concerns should understand the great advantages they would derive from membership of the Association, when they had difficult problems to solve. They could then call upon men of the widest experience for assistance which would prove invaluable to them. Further, it was only by combination that the industry had been able to secure the satisfactory results which had been achieved so far. It was up to every one to support national organizations of this character; and he would like to urge the near neighbours of undertakings who were not members to use their personal influence to induce them to become so. It was hardly fair to accept advantages without contributing towards the cost.

Luncheon

In the Grosvenor Hotel, the visitors were the guests at luncheon of the Chairman and Directors of the Chester United Gas Company, with Sir John Frost in the chair. The toast of "The City of Chester" was proposed by Councillor Evans, of Wallasey; and the Mayor replied—saying that the best advertisement in the world for a gas company was a tactful and courteous body of assistants. This the Chester Gas Company certainly possessed. Mr. Mason, submitting "The Chair-

man and Directors of the Chester United Gas Company," said those present were under a deep debt of gratitude to them. The Chairman replied that it had given the Board great pleasure to welcome the "B.C.G.A." to Chester. The Company had experienced the benefits of the Association.

THE AFTERNOON SESSION.

In the afternoon there was a public conference—presided over, in the unavoidable absence of the President, by Councillor EVANS, who is Chairman of the Wallasey Gas Committee, and was Mayor of the borough last year.

Councillor EVANS said the question they had met to consider was "Public Health and Smoke Abatement." It had actually been calculated that the smoke from every ton of coal burned raw did about £1 worth of damage, which had to be paid for by the general public—whether as private individuals or as ratepayers, and including the patriotic and sensible people who did not make smoke. In effect, this meant that they allowed every raw-coal consumer to do pounds worth of unnecessary damage free of charge. This was not fair, and could not in the long run do anybody any good. Even in Chester they might perhaps learn something from the larger experience of London. In London the soot fall—which was a fair measure of the smoke curse—had been almost halved in the last twelve years. Why? Because, as Dr. Howarth, Medical Officer of Health for the City of London, said in an official report issued only last Monday, more people were using gas—and to a lesser extent electricity also (a lesser extent, because electricity was too costly) for heating, cooking, and water heating. The gas industry provided a means of diminishing, and eventually abolishing altogether, the serious damage done by smoke. They wanted the public to know two things—first, how appalling and costly this damage was; and, secondly, that gas could put an end to it with positive direct advantages to those who used it instead of burning coal.

SMOKE AND THE PUBLIC HEALTH.

Mr. D. RENNET, M.B.E., M.D., D.P.H. (Medical Officer of Health to the City and County Borough of Chester) addressed the conference on "Smoke and the Public Health." He said it is only comparatively recently that the full benefits of the radiant energy of the sun have been appreciated. It is now known that exposure to sunlight has in very many conditions curative effects which are little short of marvellous. In some conditions the sun has taken the place of the surgeon; and if it operates at a more leisurely rate, the finished result is infinitely superior. Exposure to sunlight acts beneficially on the whole organism, not merely on diseased conditions. Blood has the power of absorbing a certain energy from the sun's rays, and carrying it to every tissue and organ of the body, to their great advantage. Some of the most active rays of sunlight are absorbed in the atmosphere much more readily than others; and as they are originally present in comparatively small amounts, very little obstruction to sunlight by the presence of smoke in the air cuts-off these most active rays. With even a slightly smoky atmosphere, people are deprived of the most beneficial and curative rays of the solar spectrum.

What remedies can one suggest for the mitigation of domestic smoke? Apart from cooking and the provision of hot water, a fire is necessary for comfort during many months of the year. Comfort, however, does not mean a large fire, nor does it necessarily mean a coal fire. But there are serious disadvantages to both the alternatives, gas fires or electric fires. Each is too expensive for constant use; but both eliminate smoke. Apart from expense, it is doubtful if the ordinary citizen will consent to spend the evening by a gas or electric fire. There remains the remedy of a smokeless fuel, which I would commend to the fuel experts. For cooking and for occasional fires for comfort, both gas and electricity are better than coal. With each the temperature can be controlled at will with a minimum of trouble. For some cooking purposes Dr. Rennet considers electricity better than gas, while for others gas has the advantage. For the supply of hot water gas is a practical possibility; but the smokeless fuel would solve that problem in solving the problem of the ordinary domestic fire. For the occasional fire there is nothing better and more convenient than either an electric or gas radiator, with the economic advantage in favour of gas. In any case, for the sake of healthy living, whatever means may be employed, burn less coal.

THE GAS INDUSTRY'S HELP.

Mr. HAROLD HARTLEY, D.Sc., followed this up by a lecture on "How the Gas Industry is Helping to Solve the Smoke Problem." In the course of this, he stated that, when compared with electrical energy on a common heat unit basis, the price of gas now ruling is equivalent to electrical energy at less than one halfpenny per unit. Electrical energy is energy in a form which we are capable of employing efficiently; but it is to be feared that the difficulties inherent in the conversion of coal into electrical energy, which are such that the average efficiency of the country's power stations is less than 10 p.ct., will limit the use of electricity for heating purposes, for which over 50 p.ct. of our total coal consumption is employed. The coking industry, by its very nature, is in a much more favourable position; and of every 100 heat units in the coal carbonized in town's gas-works, some 75 to 80 heat units are available in the products—gas, coke, and tar. Of the two chief products of the gas-works, the coke represents some 50 p.ct. of the original heat units in the coal, whereas the gas itself represents only 25 p.ct. This is a point which is not always realized by the general public; and its greater appreciation would assist the crusade in which we are engaged. The replacement of coal by coke in boiler firing enables considerable savings to be effected. Whereas 150 p.ct. excess air is often employed with a smoky bituminous coal, coke fired under forced draught conditions requires only 50 p.ct. excess air. As to furnaces for continuous processes, where the furnace setting has to be heated-up and maintained for considerable periods, the coke-fired furnace of the self-contained producer type, with proper recuperative or regenerative systems, will be found most efficient and better for the production of reducing conditions than coal.

For many intermittent industrial processes town gas is ideal, and in this sphere can actually compete successfully with coke—even on the score of fuel consumption alone, leaving out of consideration the question of decreased labour charges and overhead charges resulting from the increased throughput of the gas-fired furnace. Two examples were cited—namely, annealing in a "Revergen" furnace, which can be carried out at a consumption of 3000 to 4000 c.ft. of 500 B.Th.U. gas per ton, and yellow brass melting in a gas-fired furnace provided with metal and air preheaters at a consumption of 2½ c.ft. per lb. on the basis of six melts daily.

As much as 6 p.ct. of the coal passed through domestic grates finds its way up the chimney as soot. The total waste of fuel in the open fireplace probably represents some 75 p.ct. of the coal used. It is computed that 35 to 40 million tons of coal are still burnt annually in domestic fires, despite the fact that during the last 22 years the sales of town gas have increased by 80 p.ct. The amount of energy placed at the disposal of the householder from the principal domestic fuels are:

			Relative Costs of Raw Fuel.
Coal at 50s. per ton	..	52,500 B.Th.U. per 1d.	.. 6·5
Coke at 50s. per ton	..	48,000 ,, ,,	.. 7·1
Gas at 9d. per therm	..	11,000 ,, ,,	.. 31·0
Electricity at 1d. per unit	..	3,400 ,, ,,	.. 100·0

Owing to the differences in the efficiency of the appliances in which the fuels are used, the variation in cost of the actual service rendered is not so great as might be concluded from the above table. For continuous use, the following relative efficiencies are obtained:

Electricity	100
Gas—in open fire	50
Gas—in flueless heater	31
Coke—in open grate	24
Coke—in closed stove	14
Coal—in open grate	26

Neglecting physiological factors, it will be seen that the cheapest means of warming a building is by the use of coke—for example, by central heating.

When we consider the question of intermittent heating, the position of gas and electricity is improved still further. When a room is required to be heated for a period not exceeding (say) three hours, the gas fire is as economical as the open coal fire. For shorter periods the gas fire is the cheaper, and is the most economical means available. Whether used for short or long periods, the relative costs of gas and electricity are as given above.

There is probably only one room in the majority of houses where heating is required continuously for a long period. In most of these cases a coke stove could be employed economically, with or without radiators in other parts of the building. The dining-room, sitting-room, and bedrooms could have, in addition, gas fires which, as an adjunct to a low-temperature central heating system producing an air temperature of about 55° Fahr., will be found economical.

The gas cooker, which has replaced the coal range in millions of cases, offers the cheapest and most convenient means of carrying-out domestic cooking, and is applicable to all classes. The best cooker of the present day will show a saving of from 25 to 33 p.ct. compared with those of the pre-war period. Further than this, steps have now been taken to render the operation of the oven entirely automatic; no attention being necessary with some ovens during the cooking period. Gas is alone at the present day in offering this convenience, and is cheap and economical. To cite one example, it is possible to bake six 2 lb. loaves for 1d., using gas at 10d. a therm. Even with electricity at 1d. per unit, it costs from two to three times as much to cook with electricity as with gas.

Coke-heated water circulators are now available in forms which enable the incandescent fire to be seen and used for room warming, and give cheap continuous service. By the use of a gas-heated geyser, which has an efficiency of well over 80 p.ct., and is one of the most efficient domestic appliances available, gas offers an alternative means of providing hot water for small property. In many of the recent housing schemes, geysers are being installed. Gas cookers are provided for the cooking, and a small open fire is fitted in the kitchen. In all other types of

house where there is an existing circulating system, the coke heater could be connected-up, or, alternatively, the gas circulator could be employed. The latter is more convenient than the solid fuel heater, and being provided with a thermostat it becomes automatic in its action. Compared with coke, however, the gas circulator is relatively expensive; and in order to cut down stand-by losses, the self-contained circulator and storage tank system has been developed, and has much widened the applicability of gas to this sphere.

Discussion.

The CHAIRMAN remarked that they had had two excellent lectures, each dealing with a different aspect of the one question.

Mr. CROWTHER said he could not conceive conditions under which cooking by electricity could be in any way superior to cooking carried out by gas. Neither could he imagine any housewife at the present time, who had gas available, seriously considering the alternative of cooking by means of solid fuel. He would like to suggest that, instead of looking to their gas undertakings to contribute something in aid of the rates, municipalities who owned them should give sums to their gas undertakings, to enable them to sell gas at a nominal price. ["Hear, hear."] What they lost in one way they would gain in another way—namely, in health. What means were they going to adopt to get the general public to take more interest in the work of the gas industry? They had the "B.C.G.A.," who were doing admirable work. Geysers were handy and efficient; but the circulator was very much more convenient, and was going to increase in popularity as time went by. One trouble at the present time was the first high cost, and some reduction would assist towards the more general adoption of this apparatus.

Councillor WRIGHT (Wallasey) pointed out that it was up to the industry to see that there were installed in houses only up-to-date appliances; otherwise the waste in gas and money would turn people away from doing what they wished them to do. They should try to put in cheaper gas fires, so as to forward the adoption of these appliances.

Mr. SMITH said that at Colwyn Bay they favoured the complete gas water circulator system, and it had been beneficial in increasing the use of gas for hot water work. Geysers called for an installation on generous lines—a large meter and a large supply pipe—and perfect ventilation; whereas with the circulator these things were not so necessary. With regard to central heating, he had put in from twenty to thirty installations, and had done it in such a manner as to secure a very good class of consumer, who was perfectly satisfied. His plan had been to bring the temperature of the premises up to a certain point, and then to reinforce this by gas fires in the rooms where extra heat was required. Mr. Crowther's suggestion for the subsidizing of gas undertakings, so as to aid the abolition of smoke, was an original one which might be followed up.

Mr. F. G. SKEMPSEY (Hoole, near Chester) remarked that Northampton had a very clean appearance, though it was a manufacturing town. The reason for this was that in practically the only industry there—boot making—gas engines were employed. Smoke emitted by locomotive engines was still one of the most prolific sources of trouble, and should be tackled. Again, he knew of a steam laundry which, from a chimney little higher than a cottage, was pouring forth a dense volume of smoke. How was it that such a thing was possible in these days? He was not aware how far it was a practical proposition that gas should be used in a steam laundry, but something should be done. Whatever might be the benefit of the present state of affairs to the proprietor, the damage to the community was probably twenty-five times as great.

Mr. TASKER (Hoole) urged that the use of gas would be on a much greater scale if the cost of appliances for consuming it were considerably reduced. However much they might advertise, unless the appliances were cheaper they would not progress greatly. The charges for installation should also be on the most reasonable basis possible. These suggestions were for the benefit of the sellers of gas and the makers of appliances intended for the use of gas.

Mr. WALTER HILTON (Chester) said he had found, working as an architect and building houses of a more or less similar type, that if one or two people could be induced to put in gas appliances, the rest would follow. ["Hear, hear."] This was the only practical way. He had found geysers with prepayment meters the best form of water heating. The way to get the general public to use gas appliances was to encourage those people who were building modern houses to instal them.

Mr. PYE said great strides had been made in the scientific development of gas fires. In the matter of smokeless fuel, he thought they were largely in the hands of the Fuel Research Board. At the moment, low-temperature carbonization was wasteful and impracticable for modern gas requirements, but he did not think it need always be so. Gas coke was, perhaps, now in not altogether the easiest form for the uninitiated public to use with complete comfort for domestic purposes, and developments might arise in the shape of an alteration in the temperature at which coal was carbonized so as to produce a fuel that would burn more readily in the open fire. He proposed a hearty vote of thanks to the two lecturers.

Mr. MASON seconded this vote, and included in it the Chairman and Directors of the Chester Gas Company, for their cordial welcome and generous hospitality, as well as Mr. Pye and his staff, who had worked so hard to make the conference a success. A great thing about the gas industry was that it ran parallel with the public good.

The CHAIRMAN remarked that in a bedroom with no fireplace he had put an electric radiator; but it gave off such a bad smell that he had to have it removed. The laundry to which reference had been made could get over the smoke difficulty by using coke; but there would then be less washing to do. [Laughter.]

Dr. RENNET, in acknowledgment, said he could not spend an evening by a gas fire or an electric radiator. In their isolation hospital they had installed electric cooking. After six months' experience of it, he had no hesitation in saying the oven work by electricity was superior to the oven work by gas. With the gas oven there was a constant stream of air from near the dusty floor passing over the meat; the electric oven was practically hermetically closed. For boiling, electricity was too slow.

Dr. HARTLEY said that, with regard to electric cooking, he could not agree with Dr. Rennet. As the result of full tests, he declared that if two joints of equal quality were cooked, one in a gas oven and the other in an electric oven, it would be impossible to detect any difference. Of course, if desired, one could procure gas ovens so made as to prevent the passage of air over the meat, to which Dr. Rennet had objected. Certainly the electric hotplate was slow in operation. It was not to the advantage of the apparatus manufacturers to make gas appliances that would not sell; and their aim was to render it possible for these appliances to do their work with the least practicable expenditure of gas. Consonant with making a sound article, the cost was kept as low as possible.

A GAS EXHIBITION.

The conference coincided with a week's gas exhibition in the same building, and during the day the visitors took the opportunity to inspect the display. It was an excellent little exhibition on the most practical lines; and when the writer looked in during the afternoon all the chairs were occupied by housewives who were listening to a cookery lecture and demonstration that were being given by Miss N. Longworth. There was, indeed, convincing proof of the success that attends efforts of this character to popularize still further the use of gas for cooking.

Four of the Radiation firms took part in the exhibition, there being two well-arranged stands on each side of the hall. On one side were Messrs. John Wright & Co. and Messrs. Fletcher, Russell & Co.; and on the other the Richmond Gas Stove and Meter Company and Messrs. Wilsons and Mathiesons. Samples of the latest types of cooker were on view, with details of the Gas Company's hire and purchase system, and in the centre of each stand was a handsome modern gas fire in appropriate surround. There was also a selection of water heaters, &c.

At one end of the hall was the lecture platform, provided by Messrs. W. Sugg & Co. with new pattern overhead lights fitted with enamelled adjustable reflectors arranged so as to throw the illumination in any required direction. At the other end was the stand of the Chester Gas Company, an interesting feature of which was an attractively set-out display of bye-products resulting from the manufacture of coal gas. "Vitreosil" heat-proof globes were there, with a demonstration of their effectiveness, by means of a stream of water playing on a heated globe. Another proof of the fact that these globes are as heat resisting as they are claimed to be was the exhibition of one which had been rescued from a fire at Prestatyn which had destroyed the gasfitting. The globe was discoloured; but the application of remedial measures to one side had shown that this discoloration was not permanent. A Sawer & Purves meter in glass case exposed what so many gas consumers still persist in regarding as a mystery; and near by was a new type of Sugg burner specially designed for use in mills, being fitted with a device for filtering the air before it passes into the mixing chamber.

The body of the hall was illuminated by a number of Sugg "Littleton" cluster lamps with distance control; and at the entrance were automatic devices drawing attention to the action of the Radiation patent injection-ventilator and to the way in which "New World" cookers control their own oven heat automatically.

Society of British Gas Industries.

A very interesting gathering was held at the Town Hall, Manchester, on Tuesday, April 28, on the occasion of the visit of the Council of the Society of British Gas Industries. An invitation to luncheon had been given to the Council by the Lord Mayor (Alderman Fred J. West, C.B.E.), one of the founders of the Society and a past Chairman. Unfortunately both the Chairman (Mr. J. Wilfrid Drake) and Vice-Chairman (Mr. B. B. Waller) were unavoidably absent. Mr. Frederick C. Tilley (a past Chairman), on behalf of the Council, thanked the Lord Mayor for his kind hospitality, and in a few well-chosen words proposed his health and wished him a successful year of office. The Lord Mayor expressed his pleasure at being able to entertain his old friends during his year of office. After the luncheon, the Lord Mayor adjourned with his friends to the smoke-room, where they spent a delightful hour.

London and Southern District Junior Gas Association.—The annual general business meeting of the Association will be held at the Westminster Technical Institute, Vincent Square, S.W. 1, on Friday next, May 8.

"B.C.G.A." West Riding Conference.—There is to be, on Thursday, May 21, a British Commercial Gas Association Manchester District (West Riding of Yorkshire Section) Conference, in the Harlow Manor Hydro, Harrogate, under the Presidency of Mr. Francis Barber, the Chairman of the Harrogate Gas Company. Luncheon with the Chairman and Directors of the Gas Company will precede the business, which will include an address on "Light and Health," by Mr. R. Veitch Clark, M.A., M.B. (Medical Officer of Health of the City of Manchester), and a paper entitled "Gas as a Public Service," by Mr. Frank H. Robinson, Assoc.M.Inst.C.E. (Engineer and Manager to the Harrogate Gas Company).

GAS FOR INDUSTRY.

The paper on this subject, by Mr. C. Bryan Donkin before the Eastern Counties Gas Managers' Association [*ante*, pp. 312-14], gave rise to the following

Discussion.

The President (Mr. F. A. West) thanked Mr. Donkin for his paper, which opened up a very wide field. There were unlimited possibilities of increasing their consumption in industrial work. Could the author give them any idea of the price at which coal gas should be sold for operating these furnaces to compete with ordinary producer gas, which was used in a good many furnaces in the industrial world? It was up to them to try to bring down their costs to compete with producer gas, which was possibly one of their greatest rivals at the moment.

Mr. W. H. Mainwaring (Lincoln) inquired whether producer gas could be used in the furnaces described.

Mr. W. T. Dunn (London) asked whether the author had had any experience in regard to the quality and nature of the refractory materials used in connection with the furnaces.

Mr. Thomas Glover (Norwich) said it would be interesting if they knew just how the economies referred to were effected. A certain amount of gas of a certain calorific value was consumed, but under different conditions it gave quite different results. The time factor was very important, in addition to the amount of gas consumed. He himself had had direct evidence in confirmation of what Mr. Donkin had claimed for the type-metal melting furnaces. In this case the burner originally supplied was very inefficient, and he put down the improvement that had been effected to the fact that the gas was combusted under better conditions—the intimate mixture of the gas and air brought about more perfect combustion, and allowed of more combustion in a given area. As a matter of fact, very often they did not know, when they were burning gas in large volume, how much was being wasted; and he supposed it was the elimination of this waste which enabled British Furnaces, with their better knowledge and the improved appliances that they had designed, to effect these economies. Now these economies were very important, because they might, in some circumstances, make all the difference in deciding whether it was possible to employ town gas for these industrial purposes. Town gas would be precluded if they could not show certain figures as compared with direct firing with coal or coke. One of the furnaces to which reference had been made was a galvanizing furnace. This process was at the present time largely carried out with coke—about which they had no complaint to make, as they were coke suppliers, though they might under some conditions be very glad to carry it out with gas. He had an inquiry at the moment as to whether it could be done with town gas, and he would be pleased to be able to answer in the affirmative. At the moment it seemed to him to be rather a hopeless proposition for gas; but Mr. Donkin's firm had brought the solution a great deal nearer by these more perfect appliances. He was very glad to know there were such appliances available, because in practically every town where there was a newspaper printed metal was melted on a fairly big scale; and it was certainly a very much nicer process when done by town gas than when firing by solid fuel was employed. If the paper served no other purpose than to draw attention to this one particular appliance, it would have been useful. Newspaper offices could be very good customers indeed, and with these improved burners they would be more likely to use gas and to turn-out solid fuel appliances.

GAS FOR BREAD BAKING.

Some of the furnaces shown would only be required in towns associated with special industries; but there was one industry which was carried on in every town, and that was bread baking. Were the firm doing anything in this direction?

Mr. W. W. Townsend (Colchester) asked how the inspirator worked. He gathered that alterations in the pressure of the gas supply would not make any difference, as there was a governor, and the air supply was at a definite pressure; but was there any compensation for alterations in the calorific value of the gas? He had had experience of one of the furnaces made by the author's firm in accordance with this principle, and the inspirator arrangement worked admirably; a temperature of 1400° C. being attained very rapidly. The only criticism he had to offer—and perhaps it was not quite a fair one—was that if one wanted any other temperature than that for which the furnace was designed, it was rather difficult to reduce very much below the stated figure. There was a certain limited range of adjustment. Of course, in converting people to gaseous firing, they had to deal with the relative costs of gas and competitive fuels; but there were other advantages which were generally sufficient to turn the scale in favour of gas. A works in his own town were taking up the welding of boiler tubes by means of gas. They found the fuel consumption with gas, as compared with coke, was considerably greater; but the whole of their boiler shop was being held up owing to the time taken in welding these tubes with solid fuel. Therefore they were planning to speed-up their boiler work by adopting gas, and were satisfied, after experience, that they could do it and save a great deal of money. But, of course, to obtain consumptions of this kind it was necessary to offer specially reduced rates, and this he was greatly in favour of doing. His Company were prepared to allow a very substantial rebate for a certain consumption; and he thought they were entirely justified in doing it, to secure this extra load.

Mr. R. G. Shadbolt (Birmingham) said he had been very much struck by these three points: (1) Saving in time, which one anticipated; (2) the great reduction, generally somewhere about one-third, in the volume of gas used for a given purpose; and (3) the greatly extended range of temperatures which the improved furnaces appeared to give. The last-named was a feature which made special appeal to furnace users. It had been very difficult, for instance, to get up to 1200° C. with old-type furnaces, and then to retain this temperature; but now one could go up to as high as 1800° C. This was a great achievement; and the difference between 1200° and 1800° opened up an entirely new field for town gas for melting particularly the heavier metals.

Mr. J. Wilkinson (Nottingham) had been much interested in the remarks that had been made in the discussion with regard to a comparison between town gas and producer gas; and he could not resist the temptation to turn his mind back to a heading in a recent issue of one of the technical papers: "Why Make Coke?" When one considered the difference between the calorific value of the gas supplied by one undertaking and of that supplied by another—say, 280 B.Th.U. in the one case and 560 B.Th.U. in the other—and took into account the factors to which attention had been drawn, one was inclined to wonder whether one was on the right lines, or regarding the matter in the true perspective, when remaining content to follow in the paths of these two extremes.

A UNIFORM GAS?

He was not at all sure that the time had not arrived for giving serious consideration to whether a uniform calorific value throughout the whole of the country would not ultimately be in the best interests of the gas industry. ["Hear, hear."] He had given careful thought to this, and had come to the conclusion that it was time for them to give earnest consideration to the question of what was the best calorific value gas to supply in the interests of the community at large and of the industry as a whole. There were, of course, individual circumstances and individual interests; but it did appear to him that, with conditions as they operated to-day, there was too wide a margin of opinion among representatives of the gas industry as to what was the right gas to supply to the public generally. They would have made a very great advance when they could agree as to the most advantageous calorific value of gas to supply. He did not say it should be one extreme or the other, but he maintained that they should concentrate their energies upon the question, and endeavour to arrive at a decision. This would greatly assist in bringing into still more general use the furnaces and other appliances to which reference had been made in the paper. It would be a big step towards the maximum possible use of gaseous firing in place of solid fuel.

Mr. W. M. Mason (London) pointed to the part taken by the "B.C.G.A." in dealing with inquiries regarding industrial gas apparatus, and indicated the valuable character of this co-operation. Printing works could not, he said, afford to-day to go on in the old way, because they wanted to keep down their costs. The "B.C.G.A." had in their offices a record of 3000 trades, and there was an average of seven processes in each of these trades to which gas was actually being applied. During the last big coal strike, the Glasgow Gas Department kept the big newspaper of that city going because of the gas they supplied, not only for the melting of the type, but for many other purposes as well. Two years ago, the "B.C.G.A." had a conference at Liverpool, and one of the most interesting visits in connection with that event was to the biscuit factory of Messrs. Jacobs—an all-gas factory, where huge quantities of gas were consumed daily. The big installation there had started in a very small way; but it had been carefully nursed by the Distribution Superintendent, who still kept an eye constantly upon it. In these circumstances, the increase in gas consumption every year since the start had been progressive. Mr. Glover had made reference to baking, which was a tremendous field, extending throughout the country. Another sound industrial proposition was "fish and chips." In fact, the whole industrial section offered enormous possibilities, which were ample justification for the greatest optimism regarding the future of the gas industry.

Mr. F. Prentice (Ipswich) supported the vote of thanks to the author, remarking that the name of Donkin had been one to conjure with in the gas industry throughout the whole of the forty years during which he (the speaker) had been connected with it. Judging from what they had heard that day, this proud position was not likely to be assailed.

The Author Replies.

Mr. Donkin said he had been asked how producer gas compared with coal gas. Well, he was afraid it did not really. Producer gas was made so very cheaply that, where a consumer had a large producer plant, it would be necessary to bring the price of town gas down very low—under 1s. 6d., and probably nearer 1s. per 1000 c.ft. —in order to compete with it. One would not get these very high temperatures with producer gas, but perhaps 1100° or 1200° might be reached. The furnaces to which he had referred in his paper could be adapted for use with producer gas; it meant just a different arrangement of the mixing apparatus. Refractories formed really a special branch of the industry, about which he could not say very much. Mr. Glover had asked the cause of the increased efficiencies of these furnaces, and had really answered his own question by saying it was probably due to the intimate mixing of the gas and air. The inspirator was some distance from the burners, and the gas and air were mixed there and continued to be mixed all the way to the burners. Thus one got a proper, homogeneous mixture, and therefore practically complete combustion.

Mr. Glover: What would be the mixture at the point of combustion—how much air and how much gas?

Mr. Donkin replied that it would be somewhere about 6 to 1. Galvanizing could be done with gas to compete with coke, if gas was fairly low in price. Probably at 1s. 8d. to 1s. 10d. per 1000 c.ft. it would compare with coke. Of course, there were other advantages with gas which enabled it to compete with coke; and he knew of one very large galvanizing works now which was going in for gas. Storage space for fuel was a very important question with many undertakings. His firm had designed a furnace—and there was one at work in Derby—for baking. He heard it was giving extremely good results. A point had been raised about changes in the calorific value of gas supplied to the furnaces. He did not see how they could very well make an inspirator which would compensate for alterations in calorific value, and so they must rely upon the gas being fairly constant in this respect. Range of temperature involved the efficiency of the furnace. If they wanted the highest possible efficiency, it was necessary to design a furnace for the work it had to do. Of course, 1800° C. was a very high temperature; but the oven type could run up to 1650° C., and it was very useful to have

furnace which would do this. He personally agreed thoroughly with what Mr. Wilkinson had said with regard to uniform B.Th.U. It would be a tremendous help to designers of gas apparatus to be able to cater for one value of gas. The "B.C.G.A." were most helpful in putting manufacturers in touch with possible customers. "Fish and chips" in many places had boosted gas consumption wonderfully. This was a branch his Company had been looking into, and might probably take up in combination with breadmaking.

SCOTTISH JUNIOR GAS ASSOCIATION.

(WESTERN DISTRICT.)

The 21st Session of the Western Juniors was brought to a close on Saturday, April 25, when, on the invitation of the Town Council of Renfrew, a large party visited the gas-works in the Royal Burgh, for the purpose of inspecting the new vertical retorts. The party were welcomed on arrival by the Convener of the Gas Committee, Bailie M'Queen, and the Engineer and Manager, Mr. D. S. Munn, who was a member of the first Council of the Western Juniors.

The Renfrew Plant.

The new plant consists of an installation of Woodall-Duckham retorts of the latest design, capable of carbonizing 44 tons of coal in 24 hours, and comprises eight continuous vertical retorts in two settings of four, each setting having its own producer, regenerator, waste-gas flue, and damper. Each retort is built entirely separate from the adjacent ones, thus allowing for either one, two, three, or four retorts in each setting to be worked at one time.

The retort house consists of a steel-framed structure strongly braced together by means of trimmers, and filled in between with 4½ in. brickwork reinforced with "Exmet." The waste-heat boiler is of the Woodall-Duckham firetube type, constructed by Ruston & Hornsby, Ltd., of Lincoln, and is capable of raising about 1000 lbs. of steam per hour at a pressure of 120 lbs. per sq. in.

Coal for the plant is brought in wagons on an elevated railway siding at one side of the coal store, into which the coal is discharged by means of either of two electrically-operated end-tipping rams constructed by Messrs. Babcock & Wilcox, through a concrete receiving hopper built under the siding. From this hopper the coal is fed into a small receiving hopper placed in the coal store floor, and thence passed into a single-roll breaker of Babcock & Wilcox design capable of dealing with about 25 tons of bituminous "run of mine" coal per hour. The broken coal, together with the fine coal passing through the screen, is fed by a specially-designed rotary filler into a gravity bucket conveyor of a standard type, as manufactured by Messrs. Babcock & Wilcox, of about 25 tons per hour capacity. This conveyor elevates the coal and discharges it into hoppers above the retort bench, which are designed to hold sufficient coal for 48 hours' maximum consumption. To drive the mechanism for the coke extractors, two gas engines are installed, each capable of developing 1¼ B.H.P. as a maximum load. One of the engines acts as a stand-by.

The whole of the electric current required for the plant is supplied by duplicate electric generating sets, one acting as a stand-by. Each set consists of a 44 B.H.P. "National" gas engine driving a 26 KW. dynamo by means of a belt. The current generated is alternating at 440 volts, 25 cycles, 3 phase, when running at a speed of 750 r.p.m. The dynamos and motors are the manufacture of the Lancashire Dynamo Company.

The plant is specially designed to allow an extension of a further setting of four retorts to be made at some future date.

Complimentary Remarks.

After the inspection, the party adjourned to the Town Hall, where they were entertained to tea—Bailie M'Queen presiding.

Provost M'Gregor, welcoming the Juniors to Renfrew, said that, in a progressive burgh such as theirs, they always were glad to have a visit from a body whose aim was the advancement of their general knowledge.

Mr. J. M'Isaac, President of the Western Juniors, said that the visit was a fitting close to the session. He thought that everyone present would endorse his opinion when he said that the entire layout was compact, complete in every detail, and a credit to the Burgh. He thanked the Provost and Council for the privilege of seeing their works, and hoped that the results which were bound to come in the near future would fully justify the capital expenditure involved.

Mr. Munn also expressed his pleasure at having the Association at his works. He mentioned that twenty years ago the Juniors had visited Renfrew, when their output was approximately 46 million c.ft. against 115 millions to-day.

Various other speakers followed, each passing complimentary remarks on what they had seen in Renfrew.

Illuminating Engineering Society.—A meeting of the Society will be held on Tuesday, May 19, at the "E.L.M.A." Lighting Service Bureau, No. 15, Savoy Street, Strand W.C. 2, at seven o'clock, when a paper on "A Survey of Lighting in 800 Retail Shops" will be read by Messrs. W. J. Jones and H. Lingard.

COKE AS A FUEL FOR ROAD VEHICLES.

At a recent meeting of the Institution of Engineering Inspection, Mr. Thomas Clarkson read a paper on "The Evolution of Steam Boilers for Special Purposes," in which he paid particular reference to their use in road transport.

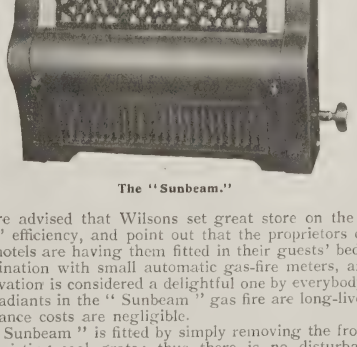
During the discussion the question of the use of coke as a fuel for 'buses and commercial vehicles was referred to.

Mr. Skinner suggested that the only difficulty in utilizing gas coke in a boiler of the type described was the clinkering trouble. Almost every small town had a gas-works, and filling stations could be erected throughout the country with, perhaps, only a few miles in between—not necessarily because the gas-works were only a few miles apart, but because the filling stations could be supplied from the gas-works near at hand. Therefore, instead of advocating boilers which utilized coal to better advantage than before, they should advocate the use of coke in the national interest.

Mr. Clarkson said there was no difficulty in using coke. Many of the boilers in this country were working on nothing but ordinary gas coke; and there was a report in "The Times" the other day of a firm in Preston running about 24 wagons 12,000 miles per annum on gas coke alone. Some of the wagons were still running well after having done 140,000 miles. The commercial aspect was to consider how many B.Th.U. one got for a penny. Petrol at (say) 2s. per gallon gave about 5000 B.Th.U. per penny, but with coke at £2 per ton they got 50,000 B.Th.U. per penny. As regards clinkering, there was no difficulty at all. Runs of over 100 miles per day had frequently been accomplished without clinkering. The small amount of clinker formed was porous and friable, and did not cling to the bars at all. The use of coke should be extended, though not, perhaps, for passenger vehicles, though it had been used for this purpose. There was a certain amount of sulphur in the coke which had to be reckoned with. The trouble could be got over by lime washing the coke before use, which effectively absorbed the objectionable sulphur in drying. During the war 'buses were run on the London streets with lime-washed coke. At that time, however, they had not the advantage of the new type of boiler.

THE "SUNBEAM" GAS FIRE.

We hear from Wilsons & Mathiesons, Ltd., of Leeds, that their "Sunbeam" gas fires have had a tremendous sale during the last autumn and winter, bringing the year's total to well over the previous high record of 1923. This is very interesting, as indicating not only the permanent hold that this type of gas fire has obtained on the public, but also that its efficiency and general behaviour are such as will justify confidence in its continued success.



The "Sunbeam."

We are advised that Wilsons set great store on the "Sunbeam's" efficiency, and point out that the proprietors of well-known hotels are having them fitted in their guests' bedrooms, in combination with small automatic gas-fire meters, and that the innovation is considered a delightful one by everybody. The curved radiants in the "Sunbeam" gas fire are long-lived, and maintenance costs are negligible.

The "Sunbeam" is fitted by simply removing the front bars of the existing coal grate; thus there is no disturbance or covering of the canopy, &c. We are told that a large stock of these fires is being built up by the manufacturers, in anticipation of a considerable demand in the coming autumn.

Institution Meeting.—Members intending to be present at the forthcoming annual meeting of the Institution of Gas Engineers are requested to send in their reply forms by Saturday, May 9, at the very latest, as it is essential that the number attending should be known by that date in order that the details of the arrangements may be completed.

CORRESPONDENCE.

[We are not responsible for opinions expressed by Correspondents.]

Combination Gas and Electricity Supplies.

Sir,—It would be a pity if Mr. Broadbent's question at a recent meeting of the London and Southern Junior Gas Association, reported in the "Journal" for April 22, p. 247, was not answered. It was to the effect that he would like to know whether anything had come of the co-operation between gas-works and electricity works referred to by me when I had the honour of reading a paper before the Association. The answer is that I can speak of the following, because I am concerned in them.

The Crowborough Gas Company put their Electricity Act into force, and are now running a combined gas and electricity undertaking. The Swanage and Oakham Gas Companies obtained Electricity Acts, and both these Companies are now running combined gas and electricity undertakings. The Port Talbot Corporation have placed contracts for electricity plant to be erected on their gas-works—the two undertakings to be run together. Spalding Urban District Council are about to call for tenders for plant to do the same thing. Retford Corporation are only awaiting the consent of the Electricity Commissioners to carry out the scheme. The Horley Gas Company's Electricity Bill was reported fully in the Technical Press just recently. [See "Journal" for March 25, p. 750; April 1, p. 63; April 8, p. 128.] There are several other cases that are not sufficiently advanced at the moment to mention, and there are several combinations of gas and electricity in which I have not been concerned, and there are various committees working on the subject, with a view to carrying out the work on a larger scale.

The whole of this, however, is very small compared with a movement on foot, which, I sincerely trust, will bring about a very extensive development of the principle. I think all these things have happened since the reading of my paper before the Association, and I do not think the progress is bad, considering what a terrible country this is in which to get anything fresh carried out. (No better example could be cited than that mentioned by Lord Bearsted in the "Times" last week, when he pointed out that at least one English marine steam engine builder had been compelled to close-down the works for lack of orders, because makers had not seen or regarded the development of the internal combustion engine for ship propulsion, the consequence being that many orders for such engines were placed with Continental engine works by English shipowners.) As most people know, on the Continent and in U.S.A. control of gas and electricity is very largely in the same hands, whereas in this country it is still the exception. As I gain experience in the combination of these industries, I maintain more forcibly that it is advantageous in the largest systems and absolutely essential in the smaller districts such as thinly-populated rural areas. Estimates prepared on all kinds of bases show this.

A. Hugh Seabrook.

146, *Bishopsgate, London, E.C. 2,*
April 28, 1925.

REGISTER OF PATENTS.

Discharging and Charging Retorts.—No. 231,220.

Dempster, R., & Sons, Ltd., and Woodhead, C. J., both of Elland.

No. 29,941; Nov. 28, 1923.

This invention for discharging coke from, and charging coal into, through retorts relates to apparatus in which a spiral conveyor is mounted in a carriage and adapted to be supplied with coal from a hopper or other feeding device; the holder being provided at its forward end with one or more hinged pusher plates. Means are provided for traversing the spiral conveyor and holder through the retort so that the pusher plates discharge the coke therefrom. During this operation the spiral conveyor is not rotated and the major portion of the charge of coal which has been deposited into the spaces between the spirals is carried into the retort. On the return movement, the spiral conveyor is rotated to discharge the coal into the retort as the conveyor is withdrawn.

According to this invention, the spiral conveyor is caused to rotate at any predetermined speed in relation to its speed of withdrawal, with the result that the coal is left in the retort, being supplemented and banked up as desired.

Fig. 1 is a vertical section of the apparatus, and figs. 2 and 3 a side elevation and a plan of the first section of the conveyor.

A indicates a spiral conveyor, B the holder, C the hopper, and D the pusher plates; and the conveyor is built up in sections connected together by universal joints *a*. The holder B is also built up in sections comprising two side plates fitted with bearings *b* for the conveyor sections to run in. Each side plate has attached to it a rack b^1 for engagement with a toothed wheel b^2; and the sections are hinged together at b^3, and are provided with studs b^4 arranged coaxially with the hinges b^3. These studs travel round curved guide rails mounted on a carriage F, which runs on rails *f* and can be traversed past the retorts. Mounted on the carriage below the front section of the conveyor and holder is a slidable bridge. The front conveyor section is fitted with the pusher plates D, which are shown in the form of doors hinged to the side plates B. The back section is connected by a universal joint with a shaft H, on which is a bevel wheel *h* gearing with a bevel wheel h^1 on a shaft h^2 on which is a bevel wheel h^3 gearing with a bevel wheel h^4 on a shaft h^5. On the latter is mounted a free wheel or its equivalent. The shaft h^5 is driven from the motor h^6 through the intervention of a gear box h^7 by means of which the speed of rotation of the conveyor A can be varied in relation to the speed of the toothed wheels b^2, which are driven by a belt or chain from the motor h^6.

Prepayment Meters.—No. 230,998.

Sutherland Meter Co., Ltd., and King, F. H. W., both of Birmingham.

No. 7655; March 28, 1924.

This invention is applicable to coin-controlled meter mechanism of the type covered by specification No. 227,601 [see "Journal," Vol. 169, p. 615]. It provides for a convenient form of shield or shutter to prevent tampering with the mechanism through the coin slot after prepayment has been made.

The shutter comprises a plate having a portion which serves as a handle and having a boss which engages on and extends to the end of the operating spindle. It is formed from a single piece of metal and has an integral upturned lip to form the operating handle of the coin casing.

Pressure Relief-Valve Apparatus.—No. 231,027.

Harrison, J. F., of Glasgow, and Peebles, W. C., of Bonnington.

No. 11,130; May 6, 1924.

This invention has for its object a sensitive pressure relief valve for gas or air, of simple construction, effective in action and applicable for dealing with low pressures such as occur in the handling of commercial gas—for example, relieving increase of pressure in gas retorts when there is a stoppage in the foul main or when the exhausters are inoperative.

From the cross-sectional elevation which we reproduce, it will be seen that there is provided a valve casing A adapted for connection to the pressure-loaded main. Within this casing, and controlling the exit therefrom, are double-beat valve elements A^1, A^2 of bell type having lips depending into water-seals A^3, A^4. These valve-elements A^1 A^2 are carried by a vertical spindle A^5. The spindle A^5 carries a regulating bell B arranged in a vessel B^1 above the casing A and provided with water-seal B^2. Where the spindle A^5 passes through it there is provided on the regulating bell B, instead of packing and in order to reduce friction, a dependent bell B^3 in a water-seal B. The upper end of the spindle A^5 is connected by a chain C to one end of a two-armed quadrant lever C^1, the other end of which has depending from it weights C^2 which may be varied. The bell B is externally open to the atmosphere and internally connected with the source of pressure by means of a pipe D opening into its under side. In the pipe D there is provided a valve or cock (not shown). Fresh water inlet pipes D^1 are provided by means of which the seals may be replenished, and there is also an overflow pipe D^2 in connection with the seal B^2. A pipe D^3 is provided to connect the interior of

FIG. 1.

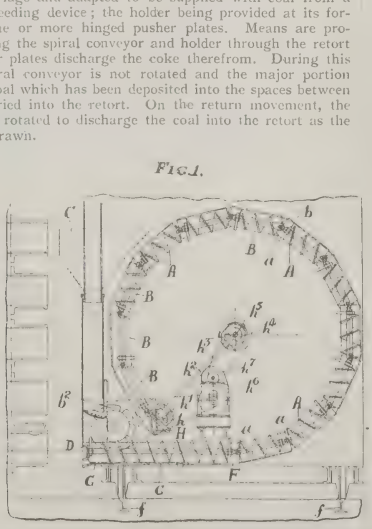


FIG. 2.

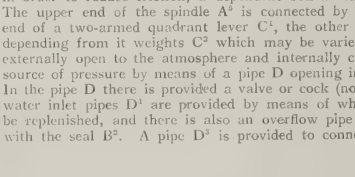

FIG. 3.

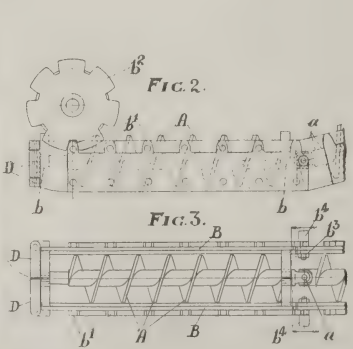
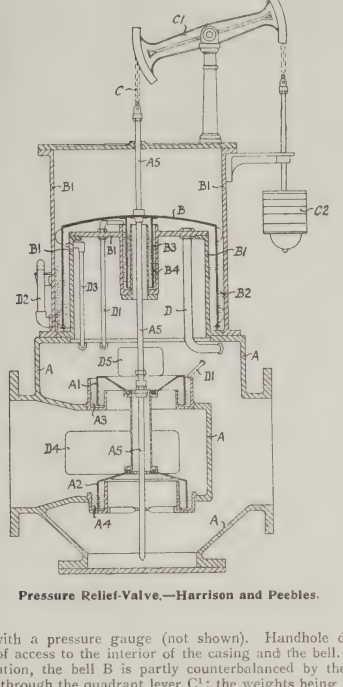


Charger-Discharger—R. Dempster & Sons, Ltd.



Pressure Relief-Valve.—Harrison and Peebles.

e bell with a pressure gauge (not shown). Handhole doors D^1, allow of access to the interior of the casing and the bell.

In operation, the bell B is partly counterbalanced by the weights acting through the quadrant lever C^1; the weights being so chosen at they, together with a predetermined pressure inside the bell, mpletely counterbalance the mechanism. When that pressure is ceeded in the pipe D, and therefore in the bell B, the bell rises, d, acting through the spindle A^3, carries with it the valve elements , A^2, so allowing escape of gas or air till the pressure is restored, hen the bell descends and so closes the valve. The valve on the pipe is set to control the rate of ingress and egress of the gas or air to from the bell B, thus steadying it and preventing the valve dancing nen the pressure is about critical.

PARLIAMENTARY INTELLIGENCE.

HOUSE OF LORDS.

Progress of Bills.

Bills read the third time, passed, and sent to the Commons: Hoyce and West Kirby Urban District Council.

Bills brought from the Commons, read the first time, and referred the Examiners: Barrow-in-Furness Corporation, Bolton Corporaon, Gas Light and Coke Company, Stockton-on-Tees Corporation.

Gas Regulation Act.

Copies were presented of drafts of Special Orders proposed to be ade by the Board of Trade under section 10 of the Act, on the pplication of the Altrincham Gas Company and the Stockton-on-ees Corporation.

The draft Special Orders relating to the East Grinstead Gas and Vater Company, Monmouth Gas and Water Works Company, and the ough Gas and Coke Company, were agreed to, on the motion of e Earl of Clarendon (on behalf of Viscount Peel).

HOUSE OF COMMONS.

Progress of Bills.

Bills read the third time, and passed: Barrow-in-Furness Corporaon, Gas Light and Coke Company, and the Stockton-on-Tees orporation.

Bills read a second time, and committed: Horley District Gas ompany (Electricity Supply) and the Rochdale Corporation.

Bill read the first time, and referred to the Examiners: Hoylake id West Kirby Urban District Council.

The Kilmarnock Gas and Water Provisional Order Bill was preented by Colonel Sir John Gilmour, read the first time, and referred the Examiners.

LEGAL INTELLIGENCE.

EXTRACTION OF TOLUOLE.

Dr. Davidson's Claim on the War Office.

The hearing of the claim of Dr. W. B. Davidson for compensation in respect of processes for the extraction of toluole from coal gas [*ante*, p. 322] was resumed last Monday before the Royal Commission on Awards to Inventors (presided over by Mr. Justice Tomlin).

Dr. *Davidson*, in cross-examination, said the question of whether to separate-out the hydrocarbons or to leave them in the gas was dependent on whether the hydrocarbons were worth more when separated than when left in the gas. It also depended on the risk run in supplying gas containing naphthalene; it was not simply a matter of £ s. d. The use of hydrocarbons for stopping naphthalene was not thoroughly well known in 1913. He had no recollection of having seen an article in the "Journal of Gas Lighting" in 1899 on the difficulty of dealing with naphthalene. Solvent naphtha, he believed, had been used for the purpose of getting rid of naphthalene. The main point was that it was detrimental to the gas. The making of gas was not a secondary consideration to the production of residuals. For town gas one had to consider the necessity for keeping-up the calorific and illuminating properties. Before the war very little toluene was produced, and what was produced was by chemical works. The gas was enriched by the addition of hydrocarbons, and petrol was one of the commonest things employed. His process differed from what was well known in 1913, in respect that it consisted in adding the toluene or benzole substitutes to counteract the loss in candle power which otherwise would have resulted. In the "Journal of Gas Lighting" of September, 1900, he believed there was an article upon the benefit of using pure naphthalene. His invention was complete towards the end of December, 1914. In connection with the investigation of the idea of his invention, a research laboratory was set-up, which cost a considerable sum.

The President said he thought it was a little unfair that a man should be out of pocket if he had incurred certain expenses on behalf of the Government in doing valuable work.

Mr. Terrell replied that he was instructed to say that the War Office would consider any application that might be made in respect of out-of-pocket expenses.

Witness said that throughout 1914 he was in the employ of the Birmingham Corporation; but he had not heard of any arrangement that his services should be placed at the disposal of the Government on condition that the Corporation should not suffer any financial loss by reason of the alteration of any of their plant.

Mr. *Ernest Walter Muddiman*, a chemist, and one of Dr. Davidson's assistants, said he carried out many experiments for Dr. Davidson in his own time, and received about £40 for such services. He made considerable research into literature, in order to see what had been done on the subject; but the result was negative.

This was the case on behalf of the claimant; and the following evidence was called on behalf of the War Office.

Sir *Wm. J. Pope* said the use of washing oil for the purpose of removing hydrocarbons, the addition of xylene for the purpose of preventing the deposition of naphthalene, and the use of paraffin for the same purpose, was well known to all chemists. The process was described in the patent of Glover; and two papers on the subject appeared in the "Journal of the Society of Chemical Industry" in 1883. One was by G. E. Davis, on the distillation of coal and recovery of hydrocarbons from the gas. There the author said that the idea of extraction of hydrocarbon vapours from coal gas was not entirely new. Caro in 1869 obtained a patent for the absorption of them in heavy oils or naphtha, using the purified gas; but the process could not have been a success commercially, or there was no doubt they would have heard more about it. In 1865 a patent was taken out by Jaeger, of Baltimore (U.S.A.), for apparatus to be used in distilling oils and other liquids from coal; and in 1875 Young obtained protection for another form of plant. About this time John Barrow patented the application of refrigeration to the collection of the vapours of solvent naphtha evolved in rubber working, afterwards absorbing them in oil. In 1882 Hardman obtained a patent for the removal of benzene and its homologues from coal gas by absorption of them in heavy coal-tar oils or naphtha. The difference, however, between Hardman's patent and Caro's process was that the former preferred to use unpurified gas, while Caro selected purified gas. Hardman also claimed the use of the gas, after being deprived of its benzole, for heating purposes; but Young in his patent distinctly said the denuded gases, after having parted with any hydrocarbon vapours absorbable by the oils, passed away, to be used as fuel or otherwise consumed. The gas, after extraction of benzene and other hydrocarbons, could be re-carburetted and utilized for lighting; some of the oils of lower boiling-point than benzole being employed for this. If benzene and toluene were required for manufacturing purposes, they could be obtained from coal tar; but previous to the war it was not considered economical to extract them. It was more important to leave the benzene in than to take it out, and the same consideration applied to toluene. The demand for toluene was comparatively small before, though it became of paramount importance during, the war. The process for doing this had been fully explained in the scientific journals.

In cross-examination, witness said the process of Dr. Davidson, with which he was familiar, had been of enormous service.

Dr. *Harold G. Colman* and Dr. *Adams* having given evidence as to the coke-oven process for extracting toluene from coal gas, and the Beckton toluene recovery process, which was described in the "Gas Journal,"

Mr. Whitehead submitted that this was a case in which the Commission would be justified in making an award for compensation, as the process was a new and novel one, and of great utility. It was not necessary, as a condition precedent to making an award for compensation, to find that there was an invention.

MISCELLANEOUS NEWS.

ALDERSHOT SPECIAL ORDER.

Application to Extend Powers Under the Capital Issues Act, 1920.

An Extraordinary Meeting of the shareholders of the Aldershot Gas, Water, and District Lighting Company was held last Thursday, for the purpose of approving an application to the Board of Trade for a Special Order under section 10 of the Gas Regulation Act, 1920, relating chiefly to the capital and borrowing powers of the Company.

The Chairman (Mr. R. W. Edwards) outlined the position as follows:—The meeting is called in accordance with the rules of the Board of Trade, to submit for the approval of the shareholders a Special Order for which the Directors have applied. The portion of the Order which requires the approval of the shareholders is as to the increase in the borrowing powers. The shareholders will probably be aware that formerly the established practice was for the borrowing powers of gas companies to be limited to one-fourth of the share capital. This was subsequently altered to one-third, which is the proportion fixed in the Company's later Acts. In the year 1920, owing to the special financial conditions arising out of the War, an Act was passed dealing with the question of raising of capital by Companies carrying on certain statutory undertakings (which, of course, included gas companies). This Act was called the Public Utility Companies (Capital Issues) Act, 1920, and among other things authorized companies, with the consent of the appropriate Government Department (in our case the Board of Trade), to issue debenture stock or borrow to an extent of one-half of the share capital for the time being issued and paid up. The Company applied to the Board of Trade, and obtained their assent to exercise any such powers. The Act was a temporary one which was to continue in force for five years from the date of its passing; which five years terminates on May 20. The Act provides that its expiration should not affect the validity of anything done in pursuance thereof; and the Company were advised that, under this saving clause, the consent of the Board of Trade would continue in force notwithstanding the expiry of the Act. Questions, however, recently having arisen as to whether this was the correct position, the opinion was taken of a very eminent Parliamentary Counsel, who advised that, while any stock actually issued before May 20 would remain perfectly valid, the Company could not after that date borrow under consents, even though such consents were obtained before that date. In these circumstances, the Directors have thought it desirable to ask the Board of Trade, by Special Order, to authorize the proportion of one-half as a permanent relation between the Company's borrowing powers and share capital. Incidentally, I believe that we are the first public utility undertaking, and certainly the first gas company, to adopt Special Order procedure for this particular purpose. The Directors have also taken the opportunity, having an Order before the Board of Trade, to include certain other matters and clauses which they think would be desirable in the Company's interests.

The Chairman then moved that the draft of the Special Order submitted to the meeting be approved, subject to any alterations which might be made therein by the Board of Trade and approved by the Directors.

The Deputy-Chairman (Mr. Thomas A. Braddock) seconded the motion, which was passed unanimously.

As the Chairman suggests in his remarks, this is the first application to the Board of Trade for a Special Order to continue the temporary provisions of the Public Utility Companies (Capital Issues) Act, 1920, which will expire on May 20 next; and if the Order is granted it will form a valuable precedent in the industry for the extension of loan capital powers, and will obviate the delay and expense otherwise entailed in seeking powers direct from Parliament by means of a Bill.

ROTARIANS AND GAS SERVICE.

At a meeting of the Bridlington Rotary Club on April 26 (Mr. Harry Davis in the chair), Mr. John Kelly (Secretary and Manager of the Bridlington Gas Company) gave an address on "The Realization of the Ideal of Rotary in the Gas Industry."

If, he said, I understand it aright, the ideal which primarily inspires Rotary is that of rendering the best service of which its members are capable. The obtaining of personal profit or advantage is secondary. Because the gas industry in this country is unique in being so constituted by law as a public utility, so far as gas companies are concerned, as to compel it willy-nilly to conform to that ideal, it is peculiarly fitting that I should address you on the public supply of town gas by gas companies. When, rather more than a century ago, gas first began its career of public service, usually by means of public companies, it was thought that the best, cheapest, and most efficient service could be secured by free competition. The evil results of unfettered competition soon made unquestionably manifest the fact that quasi-monopoly was the only method by which the true economic interest of the community could be served. Parliament therefore decided to grant such monopoly to undertakings established to supply gas in defined areas, and in order to secure that public service should be the primary consideration, made enactments to that end. Little more is possible here than briefly to draw your attention to the way in which the financial provisions of the law make service the primary, and a strictly limited profit the secondary, consideration. At first this was done by fixing a maximum price of gas, coupled with a maximum dividend, usually 10 p.ct. It must be remembered that in those days capital could not have been obtained had a lower rate been fixed; also that in most cases many years elapsed before any dividend at all could be earned, and that many more years passed before gas companies were in a position to pay maximum dividends. Companies were then permitted to establish a reserve fund to an amount not exceeding one-tenth of the nominal capital. Later on, in the 'seventies of last century, when gas had become firmly established as a public utility, and formed a safe and profitable medium for investment, Parliament, at the instance of an eminent gas engineer of that day, and who but recently died, adopted a new method a far more effective one—of securing that service should be the primary consideration in the supply of gas, and profit not merely secondary one, but an incentive to economy and sale at a low price. This was done by means of what are called the sliding-scale and the auction clauses of the Gas Acts. The auction clauses compel capital to be raised by either auction or public tender. The highest bids must be accepted, and no preference given to existing shareholders. Coupled with the auction clauses are the sliding-scale clauses which fix a standard price of gas and a standard dividend. The sliding-scale provides that, whenever the price of gas is raised above the standard, the dividend is reduced, and whenever the price of gas is reduced below the standard, the dividend may be raised. Recently this slide has been applied to the therm system, the principle being the same, but with a special provision dealing with the question of increase in costs due to causes beyond the control of undertakers.

It will be clear that this wise and far-seeing legislation has embodied the ideal of Rotary in a really marvellous way; the sliding-scale being designed to penalize any increase in the price of gas by compelling a consequent reduction in dividend from the authorized rates, and to reward reductions in price by permitting increased dividends, both according to scale. There is here no incentive whatever to obtain a high price, but an incentive to the economical manufacture and distribution of gas at as low a price as possible. Of late years, gas undertakings have been authorized to set up co-partnership schemes. Generally, a bonus to employees under these schemes is based on a sliding-scale of the same type, so that all parties—consumers, employees, and shareholders—gain by reductions in price, and lose by an increase. Commonly the degrees of gain or loss are in the region of six-sevenths or seven-eighths to the consumer, and one-seventh or one-eighth to the shareholder and employee combined.

In the case of my own Company, proceeded Mr. Kelly, the consumer gains to the extent of £770, while shareholders and employees only gain about £118, by a reduction of 1d. per 1000 c.ft., or one-fifth of a penny per therm. The principle is not a purely altruistic one, since all interests gain or lose in common by its application, but it is based essentially on the idea of service first, profit being secondary, and proportionate to the efficiency and usefulness of the service rendered. There is a great and instructive difference between the service rendered by sliding-scale companies in the gas industry, and the rewards for it, and the service and rewards of practically every other industry. In the gas industry, the higher the price of gas the lower the dividend must be. In other industries the higher the price of the commodity the higher the profits and dividends will be. In other words, outside the gas industry the financial interests of producer and seller are opposed to those of the buyer, while in the gas industry they are identical. I venture to think that, if the basic principle of the sliding-scale could be applied throughout industry it would go far to solve many of the industrial problems of the day. The effects of the practical application of the principle throughout the whole of the sliding-scale gas companies of this country is worth the consideration of those whose duty it is to deal with these problems. A further consequence of the sliding-scale is absolutely to prevent any profiteering on the part of gas companies. No doubt many people unacquainted with these facts who read of a gas company paying dividends of (say) 12 to 16 p.ct. will draw the erroneous conclusion that it is profiteering. The contrary is the fact. The capital is raised under the auction clauses. Shares are usually of a nominal value of £10, and stock nominally of £100. Dividends are paid only on the nominal values; but by the auction clauses, £20 and £30, and even more, is paid for a nominal £10 share, and £200 and £300 per nominal £100 stock. This is where the dividends are 12 to 16 p.ct. on the nominal capital. The shares are not really £10, but £20 or £30 ones, and the real dividend is usually between 5 and 6 p.ct. The important point is that, under the sliding-scale the higher the dividend the lower must be the price of gas. A high rate of dividend necessarily connotes a low price of gas, while a high price of gas equally necessarily connotes a low rate of dividend. Profiteering is therefore impossible. The high rates of dividend are merely nominal; the real rates being, as stated, usually between 5 and 6 p.ct. at present. In pre-war times the return was usually between 4½ and 5 p.ct.

Co-operation rather than competition would be the best service which gas and electricity could render. These are spoken of by the man-in-the-street as competitors; less so of late by those engaged in the two industries. I am one of those who think that co-operation would be far more fruitful to each, and of immensely greater service to the community, than competition can ever be. Public utilities, by their nature, are meant for co-operators, not competitors; and any dissipation of their energy in competition is just so much waste and disservice to the world.

Improved Nottingham Lighting.—Substantial improvements have recently been effected, to the great advantage of the city, in the illumination of Nottingham's main central thoroughfares, by the installation of new high-power gas lamps. Locally the work has occasioned the greatest satisfaction; and with the application of similar improvements to many of the districts radiating from the Market Place, the hope is entertained that Nottingham may speedily recover the position which it at one time occupied, of being one of the best-lighted cities in the Midlands.

Information Bureaux and Specialist Libraries.—The highly successful conference held at Hoddesdon in September, 1924, of Special Libraries and Information Bureaux, has resulted in financial support being obtained from the Carnegie United Kingdom Trust for a period of two years, in order to give the new movement an opportunity of becoming self-supporting. Mr. G. W. Keeling, of London (formerly of Winchester and King's College, Cambridge) has been appointed Organizing Secretary to the Committee which was formed during the conference to ensure the continued co-operation of the interests there represented. Active arrangements are being made for the holding of a second week-end conference next September, and for the preparation of a Directory of Special Libraries and Information Bureaux for the United Kingdom.

BOMBAY GAS COMPANY, LIMITED.

Ordinary General Meeting.

The Ordinary General Meeting of the Company was held at their Offices, Moorgate Station Chambers, London, E.C., on Wednesday, April 29. Mr. WILLIAM GRAHAM BRADSHAW, C.B.E. (Chairman), presided.

The notice convening the meeting and the Auditors' report on the balance-sheet were read by the Secretary (Mr. A. Dickson, Jun.).

THE LATE CHAIRMAN.

The CHAIRMAN said: We meet to-day under a deep sense of the almost irreparable loss which the Company have sustained in the death of our valued friend and Chairman, Mr. Henry Edward Jones. It is befitting, and it will, I am sure, be in accordance with your feelings, that, before proceeding to the business of the day, we should turn aside to recall the great qualities of the friend who has passed away from us, and the importance of the services which he rendered to the Company and the profession of which he was such a distinguished member. Mr. H. E. Jones was a man of outstanding ability and of striking personal qualities; in very truth he was a great man and a type of those who have made England great. Strong, virile, and courageous, both intellectually and physically, he was also tenderhearted and generous in his estimation of others. With an engaging personality and an exceptional easiness of approach, he had a force and decision of character which arrested and held attention. His great intellectual powers were trained and strengthened by an inexhaustible application, an intense concentration of purpose, and a wholehearted devotion to his work. The industry which he served with such distinction for more than sixty years conferred in his opinion a real benefit upon his fellow men. It was a constant pleasure to him to think that cheap gas brought to the working classes comfort and health, in enabling them to cook their food and warm their houses with an economy and efficiency which he believed they could not otherwise obtain. And therefore he threw the whole weight of his knowledge and enthusiasm into his profession. As a professional man he attained to the very highest position open to him. He was at various times in his career President of the Institution of Gas Engineers, President of the Institution of Civil Engineers—the blue ribbon of the whole engineering profession in this country—and the first President of the National Gas Council. In fact, he held every office of prominence which his fellow engineers could confer upon him; and he fulfilled them all with distinction and success. As a leader he was always ahead of his colleagues in every scientific and practical advance. A joint author of the sliding-scale, which has done more than anything else to establish the gas industry in this country, he was the first to apply it practically and put it into actual operation. As a friend—and nobody can speak more confidently on this point than I, for I am proud of the fact that I was his colleague and friend, here and elsewhere, for more than 37 years—he was staunch, warm-hearted, generous, wisely indulgent to the frailties of others, and ever ready and watchful to do them service. His own fidelity in friendship brought him its natural reward—the affection and confidence of his friends. It is the literal truth to say that those who knew him best loved him most. He was connected with this Company, as the Directors' reports remind us, for 33 years; and the services which he rendered to it surpass any expression of appreciation which I can give to them. He became Chairman 21 years ago, at an age when many men are thinking of seeking retirement and rest, and he sought its advancement and improvement up to the very date of his death, with unabated zeal and undiminished efficiency.

I beg to move "That this meeting desire to record their profound sense of personal and public loss in the death of their esteemed and valued Chairman and friend, Mr. H. E. Jones, and to convey to his family the expression of their deep sympathy." And I beg to suggest that we carry this resolution by standing in silence for a few moments, in token of our respect and esteem for our departed friend.

The meeting stood in silence.

The annual report of the Directors and the accounts of the Company were then taken as read.

The CHAIRMAN, in moving their adoption, said: You will, I feel sure, agree that the Directors could not have made a wiser or more appropriate choice of a colleague to fill the vacancy on the Board than Mr. S. H. Jones, the second surviving son of our late Chairman. Mr. Stanley Jones has been Chief Engineer and General Manager of the Commercial Gas Company for over twenty years. He has had an experience in that Company of gas engineering and administration for some thirty years, and has contributed largely to its continuous prosperity and success. He is giving up his position in that Company to become a Director of it, and to assume important positions in connection with other similar concerns; and I have no hesitation in saying that his knowledge and experience will be of the greatest advantage to this Company. I can wholeheartedly recommend him to you for re-election, and congratulate you as shareholders that we have such an able engineer and an administrator of such proved capacity to take a share in the management of our Company. I regret to say that Mr. A. R. Burch, our Engineer and Manager in Bombay, felt it necessary, on account of his health, to resign his office in October last. He served the Company faithfully and successfully in that capacity for eighteen years, and left it in a much stronger and more prosperous condition than he found it. I desire on the part of the Board to express our sense of the valuable service he gave to us, and our appreciation of the efficiency and ability with which he discharged the duties of his office in the trying climate of Bombay. We wish him every happiness and good health in his retirement. We have appointed in his place Mr. W. T. Lane, who has 25 years' excellent service with the Company to his credit: and I have no doubt he will fully justify the confidence in his ability and knowledge which the Directors have thereby expressed.

THE YEAR'S WORKING.

Now I turn to the record of the Company's operations for the year to which the report and accounts relate. It will be within your knowledge that the trade of Bombay, especially as regards its staple industry the cotton mills, has been during the last year in a depressed condition, all classes of the community being adversely affected by it. For a period of two months the mill industry was disturbed by a strike involving a great loss of earnings to the mill operatives and to the large body of shareholders in the mills, and causing a considerable reduction in the spending power of the public. It is a matter for congratulation that in face of these adverse trade conditions there should be signs of improvement in our own affairs. This is indicated by the increase of 3 p.ct. in the sale of gas, against a decrease of 3 p.ct. in 1923. There was no marked difference in the rate of increase at any one period of the year; the increase for the first half-year being 3·1 p.ct. and for the second half-year 2·9 p.ct. It is reassuring to note that the general foreign trade of India shows signs of improvement. The value of exports in 1922 exceeded the imports by 38 million pounds, in 1923 by 82 millions, and in 1924 by 96 millions. The value of exports in 1924 was 28 million pounds more than in 1923. As regards the Province of Bombay, the indications of reviving prosperity are not quite so clear, but are still to be seen in a smaller degree. There was an excess of imports over exports in 1922 of 2 million pounds; but in 1923 and 1924 the tide turned, and exports exceeded imports in each year by 13 million pounds. The improvement in the foreign trade of India as a whole is reflected in the course of the rupee sterling exchange, from which, as you will see, we have derived considerable benefit. Turning to the accounts, there are a few points only to which attention need be drawn. In the capital account it will be noticed that the capital issued is increased by £20,000, with £200 premiums thereon. In May last the Directors issued the £20,000 of capital remaining unissued at a small premium of 1s. for each £5 share. The market price was then, and is now, about £5 5s. per share; but this price in each case includes about 4s. per share of dividend, whereas the new shares issued did not participate in any dividend for six months, and were therefore worth 4s. less—or £5 1s., the price obtained for them. Before making the issue, the Directors made such inquiries as were open to them, in order to ascertain whether the existing shareholders were likely to take up the issue at the price named or a little less; and we were forced to the conclusion that, unless we were to issue the shares at less than their par value, which our articles do not authorize, and which we did not think was in the best interest of the Company, and therefore of the shareholders, it was preferable to sell the issue *en bloc*, reserving, as we did, a portion of it for such shareholders as cared to apply. Somewhat to our surprise, and to our great regret, some shareholders—not more than three or four—applied too late, and were disappointed: but I do not think they lost much, and the opportunity of acquiring a larger holding in the Company will possibly recur in the not distant future, if the business of the Company continues to expand as I hope it will. The total capital expenditure for the year amounts to £8353. The expenditure on new mains amounted to £6634, the distribution system having been considerably extended and improved, some 10¾ miles of new mains having been added during the year. We must look for a considerable expenditure under this head in the future, but we shall take care to ensure that, where possible, it is remunerative. You will agree that the prosperity of the Company cannot be maintained without judicious extensions of its area of supply. The sum of £491 for land represents the purchase of rights held by the Bombay Municipal Corporation in a watercourse running through land acquired by the Company. At the close of 1923 the amount of capital expended in excess of capital raised was £62,402. This has now been reduced by £11,848 to £50,554. It will be necessary to refer to this later on, when a resolution will be submitted to the meeting for increasing the authorized capital of the Company. The total capital employed is equivalent to £958 per million c.ft. of gas sold (10s. 2d. per 1000 c.ft.). When I joined the Board about twenty years ago it was nearly double that amount. In the revenue account, the receipts from gas are less by £3190, though we sold an additional 11 million c.ft. This is accounted for by the reduction of 8d. per 1000 c.ft. in the price of gas used for lighting which was made as from Jan. 1, 1924, a reduction of 8d. per 1000 c.ft. having been made in the price of gas used for heating purposes as from Aug. 1, 1923. The concession thus made to the consumers amounts to £7700 in a full year. The receipts from private consumers were less by £4374, but for public lighting the revenue was larger by £1184. Meter rental decreased by £570, by reason of adjustments and a smaller number of meters on the district. The revenue derived from coke was less by £2700, the sales having decreased by 1190 tons; less coke being made, because a smaller quantity of coal was carbonized. During the first half of the year the demand for coke practically kept pace with production; but towards the end of the year the market was disturbed by the competition of the Bengal coke-oven companies, who, finding their local demands falling-off, dispatched coke to Bombay, and dumped it there at low rates. This action made it difficult not only for ourselves, but for our contractors, to sell against them. The selling price of coke is also affected by changes in the price of coal. At present the price of coal, and therefore of coke, has a downward tendency; and there appears to be every indication that, in common with the rest of the world, we in Bombay must look to some reduction in the very favourable rates we have been receiving for our coke during the past few years. The average yield of coke and breeze was 46s. 3·9d. per ton, compared with 45s. 7·5d. in 1923. The sale of tar was again satisfactory; the demand being always in excess of production. The average price obtained was 0·7d. per gallon. On the other side of the revenue account the expenditure is less by £1063. Coals cost £2374 more; the price per ton carbonized being 30s. 11d., against 35s. 9d. in 1923. Some advantage, however, has been gained by improved working, as we carbonized 1897 tons less coal for an increased sale of 11 million c.ft. of gas. The sale of gas per ton of coal carbonized amounted to 13,093 c.ft., compared with 12,125 c.ft. in 1923—an improvement of 968 c.ft. per ton of coal. New contracts have been arranged for the supply of additional coal at lower rates, concurrently with deliveries under an existing contract. This will afford some considerable immediate financial relief by way of averaging carbonizing costs. Owing to the smaller revenue from coke, the net cost of coal, after deducting receipts from residuals, was

7·7d. per 1000 c.ft. of gas sold, against 4·7d. in 1923—an increase of 3d. per 1000 c.ft. Repair and maintenance of works is more by £1373. A sum of £3705 was expended in rebuilding and raising the floor level of five beds of retorts, but the expenditure on other items of wear and tear was less by £2332; the result being a net increase of £1373. A satisfactory feature will be noted in the reduced costs under distribution charges, which are less by £4393. The last item of expenditure "Workmen's Compensation Insurance Fund," appears for the first time. The Government of India having passed legislation for providing compensation to workmen injured in the course of their employment, it is necessary that some provision be made for meeting possible liabilities which the Company may incur. This can be done either by effecting policies of insurance or by building-up a special fund of our own. In view of the high rates of premium asked by the insurance companies for this business, and the practical immunity the Company has enjoyed in the past from any accidents of a serious nature, it is considered that the Company will benefit by providing its own insurance fund. Coming to the net result of the year's work, the balance of profit carried to the net revenue account is £21,761. There is a profit on exchange of £5185, compared with £855 in 1923; the average rate of exchange of the rupee being 1s. 5·4d., against 1s. 4·3d., and the amount remitted being £14,000 more than in 1923. Adding this profit and deducting the interest charges and the sum of £200 commission on new share issue, there remains a net profit of £25,834 for the year. Adding to this the undivided profit of £35,051 brought forward from the previous year, we have a total available profit of £60,885. Deducting from this the interim dividend of £12,000 paid in November last, and the usual additions to the reserve funds, amounting to £2675, there remains £46,208, out of which a final dividend of 4 p.c. is recommended, making 8 p.ct. for the year, leaving £34,208 to be carried to the current year, which is only £843 less than was brought in. I would, however, remind you that, in addition to the sum of £2675 added to our reserve funds, ample provision has been made in the revenue account before the balance of profit is arrived at for the upkeep of the works and distribution plant and for depreciation.

A COMPARISON.

I think that the following figures, which will give you a comparison of the state of the Company in 1910 and at the end of 1924, will enable you to form a fair estimate of the condition and progress of the business. The year 1910 has been selected for the comparison only because it is fifteen years ago, and fifteen years is a reasonable period to take. I would remind you that it includes the difficult years of the war and the period of high prices and increased wages which followed it.

—	1910.	1924.	Increase.	P.Ct.
	£	£	£	
Total capital expended	257,356	357,195	99,839	38
Total capital and premiums raised	240,000	306,640	66,640	27
Balance of capital expended over capital raised	17,356	50,555	33,199	..

—	1910.	1924.	Increase.	P.Ct.
	C.Ft.	C.Ft.	C.Ft.	
Gas sold	198,000,000	373,000,000	175,000,000	88
	£	£	£	
Revenue from gas	59,452	109,281	49,829	82
Total revenue	74,794	158,038	83,244	111
Revenue expenditure	56,153	136,277	80,124	142
Profit on revenue account	18,641	21,761	3,120	16
Dividend payment	16,800	24,000	7,200	42
Rate of dividend	7 p.ct.	8 p.ct.	..	..
	£	£		
Reserve funds	23,731	56,241	32,510	..
Carry forward	5,357	34,208	28,851	..
Temporary loan	15,000	1,000	14,000 decrease	..

I think you will agree with me that those figures show that the Company has grown not only in size, but also in strength and prosperity. With regard to the outlook, I have no inclination to attempt to prophesy. I have tried to put before you a fair summary of the work of the past year and the present position of the Company, and you can judge for yourselves as to its prospects. I will only add that, apart from extensions of mains and the provision of stoking machinery and coal and coke handling plant, which the changed attitude of labour in India may render advisable, we have no large capital expenditure before us. Our manufacturing works are sufficient for some years to come; we have paid off the whole of our Bank loan; and there are no debentures or mortgages upon the Company. The business increases steadily, if slowly, in spite of the tremendous competition of cheap electricity generated by water power, and the advantage which the Electricity Company gain in having a large proportion of Indian shareholders whose influence in Bombay is enormous. Our European staff are experienced and able, and are devoted to the interests of the Company. Our native staff and workpeople are beginning I think to realize that their employers have their welfare at heart, and can do better for them than all the agitators with their specious promises and allurements. The Company is stronger and better equipped than it has ever been, and in a good position to take advantage of any improvement which may take place in the trade of Bombay; and I venture to express the hope that, when next we have the pleasure of meeting you, we may have as favourable a report to present to you as we have to-day.

Mr. H. H. Macleod (Deputy-Chairman) seconded the adoption of the report and accounts.

Mr. W. J. Liberty pointed out that revenue from public lighting had increased, and asked whether there was competition with electricity in Bombay in respect of public lighting.

The Chairman said there was a great deal, and it was increasing.

Mr. Liberty said that, though the price of gas for lighting had been decreased, the revenue had increased, and this sounded very healthy.

The Chairman agreed that it was a healthy sign. The Gas Company were lighting most of the streets, and the Electricity Company were lighting some of the big crossings.

Mr. Liberty asked whether there was an increase or decrease of public lighting by gas.

The Chairman said that there was an increase. Public lighting had produced £1184 more in 1924 than in 1923.

The report and accounts were adopted unanimously.

THE FINAL DIVIDEND.

The Chairman proposed that a final dividend of 4 p.ct., less income-tax at 2s. 3d. in the £, be declared, payable on and after May 8, making, with the interim dividend of 4 p.ct., a total dividend of 8 p.ct.

Mr. H. H. Macleod (Deputy-Chairman) seconded.

The resolution was carried.

RE-ELECTION OF RETIRING DIRECTORS.

The Chairman moved that the retiring Directors, Mr. Louis Penny and Mr. Stanley Hunter Jones, be re-elected.

Mr. H. H. Macleod seconded.

Mr. Louis Penny said that he had tendered his resignation to the Directors on several occasions, but they had thought fit not to accept it. His reason for doing so was that he was 82 years of age, and he considered that, when a man attained this age, it was time for him to give place to a younger and more vigorous man. He had been in the service of the Company for nearly 42 years. For seventeen years he was Engineer and Manager in Bombay, for two years he was Auditor in London, and since 1902 he had been a Director. He would be sorry to give up his connection with the Company, but he considered it was time he should do so. If the shareholders thought fit to re-elect him, his intention was to place his resignation in the hands of the Chairman as soon as the latter had found a fit and suitable man to take his place.

The Chairman said that when they had got a good thing they stuck to it. Mr. Penny had local knowledge and long experience, and knew the Company more than any of them. It was wise to retain him.

Both Directors were re-elected.

Mr. Penny, expressing his thanks to the meeting, said he would keep to his resolve.

Mr. Jones also returned thanks.

RE-ELECTION OF AUDITORS.

On the motion of Mr. H. F. Hills, seconded by Mr. Bertram Ellis, the Auditors, Mr. Spencer Gore Browne and Mr. Alfred Morland, F.C.A., were re-elected.

This concluded the business of the ordinary general meeting.

Extraordinary General Meeting.

The notice convening the meeting having been read,

The Chairman moved the following resolutions:

(*a*) "That each of the existing £5 shares be divided into five fully paid-up shares of £1 each."

(*b*) "1. That the capital of the Company be increased from £300,000 to £400,000 by the creation of 100,000 new ordinary shares of £1 each.

"2. That the Directors be authorized to issue the said shares at such times and to such persons and upon such terms as they may consider expedient in the interests of the Company."

It was pointed out by the Chairman that the capital account was overdrawn by over £50,000, and the Company would have had to raise fresh capital immediately, except for the fact that the reserve fund was being used in the business. But if the Company had to expend much money in extension of mains, they would have to issue fresh capital. It would be noticed that the Directors were recommending the splitting of the £5 shares into £1 shares, and the issue of £1 shares when the fresh capital was issued. The reason was that shares of a smaller denomination sold on the market at a better price than shares of a larger denomination.

Mr. H. H. Macleod seconded the two resolutions.

The resolutions were carried nem. con.

The Chairman said that resolution (*a*) would have to be confirmed at a further Extraordinary General Meeting, to be held at the offices of the Company on May 27, at 3 o'clock.

VOTES OF THANKS.

Mr. Aschwanden tendered the hearty thanks of the shareholders to the Chairman and the Directors for the lucid manner in which the former had explained the accounts, and for the splendid way the business of the Company had been conducted during the past year. He also proposed a vote of thanks to the officers of the Company, particularly the Manager in India.

Mr. C. A. Morgan seconded, and the vote was carried with acclamation.

The Chairman, responding, expressed thanks for the manner in which the shareholders had recognized the work of the Board and the officers of the Company. He wished to bear his personal testimony to the manner in which the officers had carried out their work. As for Mr. Dickson (the Secretary) and his staff, he could not say too much. They provided the Directors with the most wonderful statistics, and, unlike a great many statistics, they were all useful. To Mr. Burch (the late Manager at Bombay) and Mr. Lane (the present Manager) and the staff in Bombay, the Company owed a deep debt of gratitude; and he was sure that those in Bombay would be most grateful to the shareholders for having passed the vote of thanks.

The Secretary expressed cordial thanks on behalf of the staff both at home and overseas.

The meeting then closed.

Reduction in Price at Congleton.—The Gas Committee of the Congleton Town Council have reduced the price of gas from 3s. 6d. to 3s. 4d. per 1000 c.ft., to take effect from April 1.

NORTH-EAST COAST COAL TRADE.

From our Own Correspondent.

There have been day-to-day ups and downs in the market, but no general change in the situation. For instance, Durham coking, which had been in slightly better demand in the previous week, has been again lacking in interest. Best Northumberland steams are said to be responding slightly to the curtailed output, and collieries fairly well stemmed for the next week or two. Gas makes are in moderate demand only, and producers are generally willing to offer substantial discounts on quoted prices for prompt tonnage.

Prices nominally are 19s. 6d. f.o.b. for Wear Specials, and 19s. 3d. to 19s. 6d. for best qualities. Some brands are obtainable at 18s. 6d. for tonnage that suits the colliery position, or through contractors who hold the coal. Seconds and others are 16s. 9d. to 17s., and are in plentiful supply.

The outlook is as black and unsettled as ever. Collieries are still closing down, and competition on the Continent continues unabated. Home demand shows no signs of improving, and it is difficult to know where to look for any change in the future.

YORKSHIRE AND LANCASHIRE COAL TRADE.

From our Local Correspondent.

There is no material alteration in the market conditions this week. House coal remains steady for the time of the year, and some of the best-known descriptions are not available for dispatch under two or three weeks. Slight reductions have been made in some directions, but there is no general lowering of prices.

The outlook in regard to gas coal is rather uncertain. A peculiar feature of this market is that many of the gas concerns have decided to buy for a period of twelve months some two or three months before the first deliveries will be made. Prices are ruling at a reduction compared with last year, and it may be that the purchasers are considering the getting price of the coal, which in West Yorkshire is more than the pit prices which the gas companies are being asked to pay.

The industrial consuming trades still remain dull, with few indications of an improvement in the immediate future, with the result that "spot" lots of the commoner grade slacks and nuts are being offered at comparatively low figures; but these are not being taken advantage of to any great extent owing to contract commitments.

The export situation continues dull, with no immediate prospect except at figures which show a great loss to the producer.

Prices at Hull at the week-end were: South Yorkshire—Hards, Association, 20s.; screened gas coal, 18s. 6d. to 19s.; washed trebles, 20s.; washed doubles, 17s. to 17s. 6d.; washed singles, 17s.; washed smalls, 13s. to 13s. 3d.; rough slack, 11s.; smithy peas, 19s. to 20s. 6d. West Yorkshire—Hartleys, 17s. to 18s.; screened gas coal, 18s.; washed trebles, 19s.; washed doubles, 17s.; washed singles, 16s. 6d.; washed smalls, 12s.; unwashed trebles, 17s. 6d. to 18s.; unwashed doubles, 13s. to 13s. 6d.; rough slack, 10s. 6d. to 11s.; coking smalls, 9s. 6d. Derbyshire and Notts—Tophards, 19s. to 20s.; washed trebles, 17s. 6d. to 18s. 6d.; washed doubles, 17s. to 17s. 6d.; washed singles, 16s. 6d. to 17s.; washed smalls, 12s. 6d.; unwashed doubles, 14s. to 15s.; rough slack, 10s. 9d. to 11s. Yorks, Derby, and Notts—screened steam coal, 15s. to 17s.; gas coke, 21s. 6d. to 26s. 6d.; furnace coke, 17s. to 17s. 6d.

COAL TRADE IN THE MIDLANDS.

From our Local Correspondent.

The market position continues to deteriorate. Soundings are proceeding with a view to the new annual contracts for supplies of gas coal. Buyers are in no hurry to come to terms, however, as they believe the economic position will give them further advantages before current engagements expire. Many of the undertakings have, of course, large commitments to fulfil under existing contracts, and these render them more independent. As regards the general industrial and household branches, values have given way further in seconds and common grades; supplies being offered at a shilling less.

The diminution in the output of nuts and beans and slacks has not sufficed to maintain the improved prices lately noted. Sellers have been glad to do business at from sixpence to a shilling reduction. At the Birchenwood Colliery in North Staffordshire, overtures have been made to the miners with a view to a co-operative scheme for keeping the concern going. A large part of the output has hitherto been coked; but owing to the uneconomic price to which coke has fallen, eighty-four ovens have been closed down for some time past, and the management regard the position as so serious that, pending the formulation of some scheme to avert total stoppage, they have decided to put their workmen, numbering nearly 3000, on a day-to-day contract of employment.

The cancellation of foreign orders has thrown large supplies of coke back on to the home market; and at present there is no sign of its recovery from the demoralization, blast-furnace sales being more difficult to negotiate than ever.

Keighley's Gas Centenary.—This month the Keighley gas undertaking celebrates its centenary. In May, 1825, the erection of the first works, at Low Bridge, was commenced, and in November of the same year the town was lighted by gas. It has been a public undertaking all the time, Keighley being one of the first towns in the country to have gas from works erected by the local authority. The Improvement Commissioners were instituted in the town in 1824, and the establishment of the gas-works during the following year was one of their first activities. The present works at Thwaites were opened in 1876.

TRADE NOTES.

A New Holmes Catalogue.

Messrs. W. C. Holmes & Co., Ltd., of Huddersfield and London, have sent us a copy of the first section of a new catalogue which they are issuing. This section contains information relating to various types of air and water cooled condensers, and particularly the Bournemouth or "super" type condenser, as supplied recently to the Fulham Station of the Gas Light and Coke Company, and the gas-works at Bournemouth, Swansea, Cambridge, Southampton, Torquay, &c. Further sections dealing with tar extractors, rotary and centrifugal washers, gas valves, purifiers, and gasholders, and chemical works equipment are in course of preparation.

CONTRACTS OPEN.

Fireclay Goods.

The Gas Department of the County Borough of Burnley are inviting tenders for fireclay retorts, bricks, and clay required for the resetting of ten beds of sixes, 15 ft. inclines. [See advert. on p. 389.]

Coal.

Tenders are invited by the Bingley Urban District Council for the supply of 6000 tons (or, alternatively, 12,000 tons) of gas nuts. [See advert. on p. 389.]

The Gas Committee of the Borough of Newcastle-under-Lyme are inviting tenders for 8000 tons of double screened and washed gas nuts. [See advert. on p. 389.]

EXTENSIONS.

Aberdeen Gas-Works.

The purchase by the Aberdeen Corporation Gas Department, at a cost of £523, of a boosting plant was recommended at a meeting of the Gas Committee of the Town Council last week. It was agreed to lay mains in Cattofield Place, and the mains in Broomhill Road and Westburn Drive are to be extended.

CURRENT SALES OF GAS PRODUCTS.

The London Market for Tar, Tar Products, and Sulphate.

LONDON, *May* 4.

There is little movement in pitch, and the price remains nominal at 41s. to 42s. per ton at makers' works.

Creosote is quiet at about 7d. per gallon net and naked.

Pure benzole and pure toluole are firm at about 1s. 10d. per gallon.

Solvent naphtha (95/160) is about 1s. 8d. per gallon.

Tar Products in the Provinces.

May 4.

The average values for gas-works products during last week were: Gas-works coal-tar, 27s. 9d. to 32s. 9d. Pitch, East Coast, 40s. to 41s. f.o.b. West Coast—Manchester, 35s. to 36s.; Liverpool, 36s. to 37s.; Clyde, 39s. to 40s.; Benzole, 90 p.ct., North, 1s. 7½d. to 1s. 8½d.; crude, 65 p.ct., at 120° C., 11d. to 1s. 1d., naked at makers' works; 50-90 p.ct., naked, North, 1s. 7½d. to 1s. 8½d. Toluole, naked, North, 1s. 6½d. to 1s. 7½d., nominal. Coal-tar crude naphtha, in bulk, North, 7½d. to 8½d. Solvent naphtha, naked, North, 1s. 5d. to 1s. 6d. Heavy naphtha, North, 1s. to 1s. 2d. Creosote, in bulk, North, liquid, 6d. to 6¼d.; salty, 5⅝d. to 6½d.; Scotland, 5⅝d. to 6d. Heavy oils, in bulk, North, 6½d. to 7d. Carbolic acid, 1s. 5d. to 1s. 6d. prompt. Naphthalene, £11 to £14; salts, £4 to £5, bags included. Anthracene, "A" quality 2½d. per minimum 40 p.ct., purely nominal; "B" unsaleable.

British Legion.—The annual report and accounts of the British Legion for 1924 have just been published, from which it is seen that the work of the Legion throughout the country on behalf of disabled men, widows, and dependants has increased during the year. During the period under review, nearly 60,000 first claims to pension were made to the Ministry, of which only 18,000 were admitted. This will give an indication of the need for an organization with the machinery and information available for the assistance of these claimants. In addition there are 600,000 officers and men in receipt of pension, over 160,000 widows, and 330,000 fatherless children. Further, six years after the Armistice, there are still 12,000 men receiving treatment in hospital. At least 500,000 cases are dealt with by the Legion's machinery every year.

Chester United Gas Company.—At the annual meeting of the employees of the Company who are shareholders under the co-partnership scheme Mr. J. P. Gamon presided. In proposing the adoption of the report and accounts for the year ended Dec. 31, the Chairman said it was a particular pleasure to meet them that day, because it was his father (then Chairman of the Company) who initiated the principle of co-partnership into the Company in 1901 by the introduction of a profit-sharing scheme. The scheme was started when a reduction in the price of the gas was confidently expected; and in the first year of operation a bonus of 3 p.ct. on salaries and wages was earned. In 1906 the scale of bonus and some rules were revised; but despite this, in 1913 the bonus had risen to 7½ p.ct. The war was not long in imposing its effect on industrial costs, and the bonus was reduced until it ceased altogether in 1918, when the price of gas was raised above 3s. 4d. per 1000 c.ft. There was no need for him to refer to the details of the new co-partnership scheme. It was highly satisfactory that the same rate of bonus as was declared in 1923—6½ p.ct.—was maintained for the year 1924, because financial conditions in the latter year were not so favourable. Nearly half the employees were now owners of stock in the Company, and the aggregate amount so held was over £2500, in addition to £1600 held by the trustees in readiness for transfer to individual co-partners now that the 1924 bonus was available.

STOCK MARKET REPORT.

THE return to the Gold Standard was perhaps the most important part of the Budget from the Stock Exchange point of view, as, though the change was expected, the actual announcement brought about a fear of increased gold exports and a consequential rise in the Bank Rate. Realizations of gilt-edged securities by nervous holders caused some shrinkage in quotations.

The Foreign Market continued in a depressed condition. The German Presidential election result, and the indefiniteness of the French Government's intentions with regard to that country's finances, doubtless contributed to this, and dealings were unimportant.

The misunderstanding over the Chancellor's intentions with regard to the duty to be imposed on silk caused some excitement on the "Street." Under the impression that a protective duty was to be imposed, artificial silks were in great demand. Courtaulds rising to 10os.; but on the truth becoming known the shares fell away to 96s. 6d. Motor shares responded to the proposed resumption of the McKenna duties. Humbers were particularly strong, rising to 37s. 6d. It remains to be seen, however, whether the loss of business, which chairmen of companies reported as a result of the removal of the duties, will be recovered.

There was a reactionary tendency in South African gold shares, the return of the sterling exchange to parity causing a loss of income to the producers.

In the Gas Market there is little to record. Quotations are still inclined to fall; but it is not anticipated, having regard to the improvement that is probable by reason of the reduced rate of income-tax, that this will continue, except perhaps in isolated cases where there have been few transactions of late. An exception to the rule is a rise of 1 point in the Sheffield stocks on the home Exchange. British ordinary dropped 2 points, to 110-115; Croydon sliding-scale 1½ points, to 98-102, and Gas Light ordinary a further 1, to 84-86. An issue of £12,000 5 p.ct. Perpetual Debenture stock at a minimum price of £95 has been announced by the Hayward's Heath District Gas Company.

The following transactions were recorded during the week:

On Monday, Alliance and Dublin 66¾, Bombay 5⅜, European 7⅛, 7¼, Gas Light and Coke 85¼, 85⅜, 86, 3 p.ct. debenture 60⅝, 61½, Imperial Continental 179, 181, Montevideo 66, Newcastle 3½ p.ct. 79⅛, Oriental 104½, 105, Primitiva 10s., 4 p.ct. debenture 1911 6½, South Metropolitan 94½, 95, 3 p.ct. debenture 60½, 61. Supplementary prices, Brentford 7½ p.ct. mortgages 101, Dover 5¼ p.ct. debenture 102½.

On Tuesday, Bombay 5⅞, British 111, Commercial 4 p.ct. 86⅞, Continental Union 35⅞, 35⅝, 36, European 7, Gas Light and Coke 85, 85⅛, 85⅜, 4 p.ct. preference 70, Imperial Continental 180½, 181, Primitiva 9s. 9d., 10s., South Metropolitan 94¼, 94⅝, 6½ p.ct. debenture 103½. Supplementary prices, Croydon 7½ p.ct. preference 101½, 101⅞, Grays and Tilbury "B" 8⅝, 8¾, Wandsworth 3½ p.ct. new 96½.

On Wednesday, Alliance and Dublin 66, 66⅞, Bombay 5⅛, 5⅜, 5¼, Commercial 4 p.ct. 86⅛, Gas Light and Coke 84⅞, 85, 85⅛, 85⅜, 85⅝, 85⅞, 3½ p.ct. maximum 63⅜, 4 p.ct. preference 70¾, 3 p.ct. debenture 60⅜, 61, Imperial Continental 181½, 181⅞, Primitiva 9s. 9d., 10s. 1¼d., South Metropolitan 94⅞, Tottenham "A" 118, Supplementary prices, Dover 5¾ debenture 102½, Southgate and District 5 p.ct. debenture 98½, Sunderland 6 p.ct. maximum 104.

On Thursday, Alliance and Dublin 66⅞, Continental Union 7 p.ct. preference 88, Croydon sliding-scale 100, 101, Gas Light and Coke 84⅞, 84½, 84⅞, 85, 85⅛, 4 p.ct. preference 70½, Imperial Continental 180¾, 181⅛, South Metropolitan 94, Wandsworth, Wimbledon 5 p.ct., 105.

Conditions in Lombard Street became quite comfortable with the turn of the month; the distribution of nearly £50,000,000 in dividends and other payments assisting the position. There was no keen demand for money; and while 3½ p.ct. was paid for overnight advances balances were ultimately available at 3 p.ct. The fear of a higher Bank Rate showed itself in the rate at which Treasury Bills were allotted, the average being 3s. 7d. p.ct. above the previous week's average, or £4 8s. 4½d. p.ct.

The gold standard assisted sterling, a fresh record being created; the final quotation on New York being 4.84⅝. French francs were a little stronger, and closed at 92.42½. Belgian francs closed at 95.52½, and Italian lire were finally lower at 117.62½.

There was a firmer tone in the Silver Market, and the cash price rose to 31⅝d. per oz. Gold remained at 84s. 11½d. per oz.

The Bank Rate is 5 p.ct., to which it was raised from 4 p.ct. on March 5. Bankers' deposit rates are 3 p.ct. The deposit rates of the discount houses are 3 p.ct. at call and 3¼ p.ct. at notice.

GASHOLDER AND TANK CONSTRUCTION AT THE SUTTON GAS-WORKS.

1,000,000 cubic feet capacity.

By F. SOUTHWELL CRIPPS.

Price 10/6 net.

WALTER KING, LTD., "GAS JOURNAL" OFFICES, No. 11, Bolt Court, Fleet Street, E.C. 4.

Birmingham Gas Department.—In the "JOURNAL" for April 5, p. 189, it was mentioned that the Gas Committee, in a report presented to the City Council on April 7, recommended the purchase of six small motor cars for the use of meter inspectors. The motion as carried; and Wolseley cars are to be provided.

L.C.C. and the South Metropolitan Gas Bill.—Acting under the authority of the London County Council, the Parliamentary Committee caused a petition to be deposited against the South Metropolitan Gas Bill; and they are in negotiation with the promoters with a view to a settlement, if possible, of satisfactory amendments.

Rotherham Gas-Works.—In his report of the undertaking for the year ended March 31, Mr. J. S. Naylor, the Engineer and Manager of the Rotherham Corporation Department, says the quantity of coal carbonized was 9291 tons, at a cost of £10,524, as against 8847 tons last year, costing £7741. The quantity of gas sold was 22,448,000 c.ft., or 1,612,240 therms, compared with 309,682,000 c.ft., or 1,548,410 therms. The net profit was £2459, which figure compares with £4797.

Coal Contracts at Stoke-on-Trent.—The Stoke-on-Trent Town Council, at their last meeting, passed the following resolution, which was submitted by the Gas Committee: "That on the conclusion of the existing contracts for coal, and before an order for coal or fuel of any kind is given in the future to any colliery company or agent, tenders therefor shall be advertised, and all particulars of such transactions, including prices and tests made by the Gas Engineer, shall be submitted and approved by this Committee."

Exhibition at Worthing.—Last week the Worthing Gas Light and Coke Company held an exhibition at the Rivoli Hall, Worthing. A wide range of gas appliances was shown, and there was also a demonstration of the bye-products recoverable from coal by distillation. The exhibition was the first of its kind to be held in Worthing, and it reflects great credit on the Gas Company for their enterprise, and on Mr. E. T. Hewitt, the District Superintendent of the Company, for his ingenuity in arranging the exhibits. All the fitting necessary in connection with the exhibition was done by employees of the Company.

L.C.C. and the Gas Light and Coke Company's Bill.—The Parliamentary Committee (No. 2) report to the London County Council that, acting under the authority of the Council, they caused a petition to be deposited against the Gas Light and Coke Company's Bill. In consequence of this opposition, and the opposition of a number of other petitioners, the clauses which sought to enable the Company to supply power gas and to lay mains and pipes for such purpose were withdrawn. In connection with the provision enabling the Company to stop up a footpath which leads from North Woolwich and Gallions Railway Station through the Company's works at Beckton to the Council's northern outfall works, a clause was agreed to with the promoters to enable persons proceeding to the outfall works still to use the footpath, and to preserve the right of the Council to maintain the sewage pumping mains now existing thereunder. A clause was also agreed for the protection of the Council under the London Building Acts in regard to various proposals contained in the Bill. In the circumstances, it was not necessary for further action to be taken on the Bill.

New Capital Issues.—Messrs. A. & W. Richards, of No. 37, Walbrook, E.C., are offering for sale by tender £10,000 of 5½ p.ct. perpetual debenture stock in the York Town and Blackwater Gas Company, at the minimum price of par. Tenders must be sent in by Tuesday morning, May 12. They are also similarly offering £20,000 of 5 p.ct. irredeemable preference stock in the Guildford Gas Light and Coke Company. The minimum price of issue is £90 per £100; and, as will be seen from an advertisement on another page, tenders have to be sent in by Thursday morning, May 14. Both the North Middlesex and Littlehampton Gas Company issues by the same firm were over-subscribed. For the £10,000 of additional ordinary stock of the North Middlesex Gas Company, the prices ranged from £122 down to the minimum of £117 10s. per £100. In the case of the Littlehampton Gas Company, the prices for the £5000 of 6 p.ct. redeemable debenture stock ranged from £104 down to the minimum of par.

During the year ended March 31, the sales of gas by the Dewsbury Gas Department were increased by 24,700,000 c.ft.

Permission has been granted by the Public Control Committee of the London County Council for the Association of Statutory Inspectors of Gas Meters to visit the Finsbury gas meter testing office on June 10.

The Coroner's jury returned a verdict of "Accidental death" at an inquest held recently at Burton-on-Trent on Mrs. Burgess and George Farndale, of Horninglow Street, who were poisoned by an escape of gas from an old and defective fitting.

From last Monday, the London address of Messrs. Williamson, Cliff, Ltd., is No. 1, Central Buildings, Tothill Street, Westminster, S.W. 1; and their telephone numbers Victoria 6505 and 6506. Samples of the goods the firm manufacture will be open for inspection at any time that readers of the "JOURNAL" can make it convenient to call.

The Housing Committee of the London County Council have accepted an offer of the Tottenham District Light, Heat, and Power Company to carcase dwellings on the White Hart Lane estate for lighting and cooking, and to supply a gas installation, free of cost to the Council, except that tenants must provide incandescent burners.

On Tuesday last week there was an unusual occurrence in Birmingham—the explosion of an acetylene cylinder, due to a fire arising on a motor lorry. The result was injury to five persons. The cylinder was in the driver's cabin of the lorry; and at the time of the explosion the firemen had the fire well under control. As the flames were being subdued, the crowd closed upon the lorry; and it was then that the explosion occurred.

A Building and Allied Trades Exhibition, organized by the Birmingham Chamber of Commerce, will be held at Bingley Hall, Birmingham, from Sept. 7 to 19. The object is to stimulate progress in matters relating to house building, town planning, road construction, &c. The schedule includes electrical, gas, oil, and other illuminating and heating plant and fittings. The Lord Mayor of Birmingham is the President, and among the Vice-Presidents is Councillor John Thacker (President of the Birmingham and District Master Gasfitters' Association).

NOTICES TO CORRESPONDENTS, ADVERTISERS, AND SUBSCRIBERS.

No notice can be taken of anonymous communications. Whatever is intended for insertion in the "JOURNAL" must be authenticated by the name and address of the writer—not necessarily for publication, but as a proof of good faith.

COPY FOR ADVERTISEMENTS for the "JOURNAL" should be received at the Office NOT LATER than TWELVE O'CLOCK NOON ON TUESDAY, to ensure insertion in the following day's issue.

Orders to Alter or Stop PERMANENT ADVERTISEMENTS should be received by the FIRST POST on Monday.

UNDISPLAYED ADVERTISEMENTS; Situations Wanted, Six Lines and under (about 36 words), 3s.; each additional Line, 6d. Situations Vacant, Apparatus Wanted and for Sale, Contracts, Public Notices, &c., 9d. per Line—minimum, 4s. 6d.

FOR Motor Lorries and Railway Traffic can be seen erected at our works READY FOR DELIVERY. Inspection by your Engineer invited and a test by your Local Inspector of Weights and Measures before delivery. Every machine a High-Class Engineering Product and fully guaranteed.
CHARLES ROSS, LIMITED,
SHEFFIELD.

SULPHURIC ACID.
SPECIALLY prepared for the manufacture of SULPHATE OF AMMONIA.
SPENCER CHAPMAN & MESSEL, LTD.,
with which is amalgamated Wm. Pearce & Sons, Ltd., 36, Mark Lane, London, E.C. Works—Silvertown.
Telegrams—"Hydrochloric, Fen, London."
Telephone—Royal 1166.

SPENCER'S Patent Inclined **HURDLE GRIDS.**
THE very best Patent Grids for Holding Oxide Lightly.
See Illustrated Advertisement, April 8, p. 144.

SULPHURIC ACID.
JOHN RILEY & SONS, Limited, Chemical Manufacturers, Hapton, near Burnley, are MAKERS of Special SULPHURIC ACID ("Eagle" Brand), for Sulphate of Ammonia Making. Highest percentage of Sulphate of Ammonia obtained from the use of this Vitriol, which has now been used for upwards of 60 years. Reference given to Gas Companies

HUTCHINSON BROTHERS, Ltd.,
Falcon Works, Barnsley.
Manufacturers of
GAS METERS (Ordinary and Slot).
"FALCON" INVERTED LAMPS,
SQUARE STREET LANTERNS.
SUPERHEATER BURNERS, and
CONVERSION SETS for Street Lanterns.

PATENTS, Trade Marks, Inventions, Advice, Handbook and Consultations free. King's Patent Agency Ltd., Director B. T. King, C.I.M.E., Regd. Patent Agent, G.B., U.S., and Can., 146A, Queen Victoria St., E.C. 4, and 6, Quality Ct. (next Pat. Off.), London, W.C. 39 years' refs. 'Phone Cent. 682.

J. E. C. LORD (Manchester), Ltd., Ship Canal Tar Works, Weaste, Manchester. Pitch, Creosote, Benzols, Toluol, Naphtha, Pyridine, all kinds of Cresylic Acid, Carbolic Acid, &c.

SULPHATE OF AMMONIA SATURATORS and all LEAD and TIMBER WORK in connection with Sulphate Plants.
We Guarantee promptness with efficiency for Repairs.
Joseph Taylor (Saturators), Ltd., Chemical Plant Engineers, Blackhorse Street Mills, Bolton.
Telegrams—"Saturators, Bolton." Telephone 848.

ENQUIRIES SOLICITED.

FOR Gas Works Plant of Every Description; also SULPHATE OF AMMONIA and SULPHUR RECOVERY PLANTS.
C. & W. WALKER, LIMITED,
DONNINGTON, NEWPORT, SALOP.

APPOINTMENTS, &c., VACANT.

WHEN Filling Vacancies, please REMEMBER THE CLAIM OF THE EX-SERVICE MAN, who, other Qualifications being equal, HAS THE FIRST CALL ON YOUR CONSIDERATION.

WEYMOUTH CONSUMERS' GAS COMPANY.

APPLICANTS for the Positions of Gas FITTERS ARE THANKED for their Applications. THE VACANCIES ARE NOW FILLED.
J. T. Joyce,
Engineer and Manager.

WARRINGTON CORPORATION.
(Gas Department.)

APPLICATIONS are invited for the position of ASSISTANT ENGINEER and MANAGER.
Candidates (who must not be more than 35 Years of Age) must possess a thorough knowledge of Carbonization, Engineering Workshop Practice, and the Working-Up of Residuals, and must be able to Prepare Drawings and Specifications. A knowledge of Distribution is also desirable.
The Appointment will be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922.
Salary £350 per Annum, rising by two Annual Increments of £50 to £450.
Applications, stating Age, Training, and Experience, whether Married or Single, and accompanied by *copies* of not more than Three recent Testimonials, to be addressed to the Chairman of the Gas Committee, Town Hall, Warrington, and endorsed "Assistant Engineer."
Applications to be received not later than Thursday, May 21, 1925.
A. T. Hallaway,
Town Clerk.
Town Hall,
Warrington.

BRIDGNORTH GAS-WORKS.

GAS MANAGER WANTED.

THE Gas Committee of the Bridgnorth Corporation require the Service of a Properly Qualified and Experienced GAS-WORKS MANAGER, as soon as possible.
Applications, in own handwriting, stating Age, Experience, and Salary required, accompanied by *copies* of Three Testimonials, to be sent to the undersigned not later than Saturday, the 9th of May, 1925.
House, rent free, with Coal and Gas will be provided.
J. H. Cooksey,
Town Clerk,
and Secretary to the Gas Department.
Bridgnorth,
April 23, 1925.

COUNTY BOROUGH OF BURNLEY.
(Gas Department.)

APPLICATIONS are invited for the Position of SHOWROOM MANAGER and INTERNAL FITTINGS INSPECTOR in the above-mentioned Department.
The commencing Salary will be £307 per Annum, and will be governed by the Corporation's Grading Scheme, Grade D.1, which has at the present time a maximum of £351. These amounts include Bonus, which Bonus is liable to fluctuation in accordance with the cost of living figure.
Applicants must have had previous Experience in this class of work.
Form of Application, with Conditions of Appointment, must be obtained from the Gas Engineer, Gas-Works, Burnley.
Applications must reach the Gas Engineer, Burnley, on or before Wednesday, the 13th of May, endorsed "Gas Showroom Manager."
Colin Campbell,
Town Clerk.
Town Hall, Burnley,
April 25, 1925.

WANTED—an experienced Draughtsman. Knowledge of Gas-Works Practice desirable. Commencing Salary, £252 per Annum, less Superannuation Deduction.
Apply to the undersigned, stating Age, Qualifications, and Experience.
John H. Chew,
Engineer and Manager.
Gas-Offices,
Princess Street,
Blackpool,
April 24, 1925.

WANTED—An Experienced Inspector practically Trained in the fixing and Use of all Gas Apparatus, able to control Workmen and cultivate Business.
Apply, stating Age, Experience, and Salary required, to No. 7539, "Gas Journal," 11, Bolt Court, Fleet Street, E.C. 4.

WANTED, by a Provincial Gas Company, a Thoroughly Competent METER TESTER for Repair Shop.
Apply, stating Experience, References, Age, and Wages required, to No. 7542, "Gas Journal," 11, Bolt Court, Fleet Street, E.C. 4.

GAS Fitter wanted, must have s all-round Experience in Fixing Fires, Ge &c., and General Maintenance Work. District re Wages paid.
Apply, Stating Age, Experience, &c., to the Man. Littlehampton Gas Company, Littlehampton.

PLANT, &c., FOR SALE & WANT

GAS PLANT IN STOCK.

PURIFIERS.—Dry lutes, 10 ft. and 10 ft. by 8 ft. Also 8 ft. sq. and 10 ft. by
Condensers.—6 in. and 8 in. Vertical Pipe densers. Also Patent Baffle Plate Condenser
Livesey Washer.—6 in., 8 in. and 10 in. nections.
Tower Scrubbers.—10 by 70, 4½ by 18, 4½ by
Exhausters.—2000 to 50,000 c.ft. per hour ca
Station Meters.—4 in., 6 in. and 8 in. Co tions. Also 100 lt. and 200 lt. Meters.
Station Governors.—4 in., 6 in., 6 in. and
Gasholder and Steel Tank.—10,000 cap
Also in stock PUMPS, TANKS, VALVES, CAS IRON PIPES, TUBING, &c.
Send us your inquiries.
Firth Blakeley, Sons, & Co., Ltd.
(Second-hand Plant Depts.),
Church - Fenton, Yorks.

STEAM-BOILERS For Sale—All Si Vertical. Loco-type, Cornish, Portable, and Types of Boilers.
Apply
Grantham Boiler & Crank Co., Ltd., Grante

FOR Sale—Double Riveted Cochr Vertical BOILER, 13 ft. 6 in. by 6 ft., 1919. able for Water Gas Plant.
Full particulars from the Gas Engineer, M cambe.

FOR SALE— Complete Sets of RETORT BENCH I WORK.
Bates and Sons, Wigston Lane, Aylest Leicester.

FOR SALE—One Set of Gas Exha ING PLANT, made by the Bryan Donkin pany, Limited.
The Exhauster is capable of passing 75,000 feet per hour at 85 revs. per minute, against a gas sure of 30 in., and is coupled direct to a Horiz Steam Engine, 10 in. diameter by 14 in. stroke, wo with 60 lb. steam pressure, complete with Inle Outlet Screw-Down Valves and Hydraulic Steam lator and Equilibrium Steam Throttle Valve.
The above plant is one of Three Sets which is replaced by Three very large Sets by the same m It is in first-class condition, and can be seen run by appointment with Mr. H. Pooley, at the Ayle Road Gas-Works, Leicester.

FOR SALE BY PRIVATE TREATY.

OFFERS are invited for follow nearly new, GAS ENGINE PLANT:
One 335-b.h.p. WESTINGHOUSE VERT TANDEM (2 crank) 4 cylinder, installed 300 r.p.m. Run only 1700 hours.
One 150-b.h.p. RICARDO, 6 cylinder, 1000 r installed 1923. Run only 350 hours.
One 150-b.h.p. RICARDO, 6 cylinder, 1000 (Spare engine.)
Please write to the Electrical Engineer, A shot Gas, Water, and District Lighting Com Lynchford Road, South Farnborough.

SEDGELEY URBAN DISTRICT COUNC
(Gas Department.)

THE above Council have for disp a COMBINED STEAM ENGINE and RO EXHAUSTER, Capacity 10,000 c.ft. per hou Waller and Son.
The above is in perfect Condition and can be Working. Replacing by a larger one.
For Particulars, apply to the Undersigned, Gas-Works, Lower Gornal.
Joseph Brettle,
Engineer and Mana

DEMOLITION OF PLANT.

EDINBURGH CORPORATION.
(Gas Department.)

THE Magistrates and Council prepared to receive OFFERS for the DE LITION and REMOVAL of four GASHOL having Cast-Iron Columns with Lattice Girders of one SUBMERGED CAST-IRON GASHOL TANK, all situated on their property at Ta Canonmills.
Permission to inspect and all further Particulars be obtained on Application to the Undersign whom Offers should be addressed.
The Magistrates and Council are not bound to a the lowest or any Offer.
(Signed) H. H. Gracie,
Engineer and Mana
15, Clinton Hill,
Edinburgh,
April 30, 1925.

EDITORIAL NOTES.

The Wembley Reopening.

THE British Empire Exhibition sprang into life again last Saturday; and it seemed almost impossible, as we wandered along the well-known paths and through the same buildings which afforded so much delight and information to millions of people last year, that it had all been dormant during the long dreary winter through which we have passed. There were the huge buildings of variegated architectural design, with their white exteriors looking as clean and new as in their primal state, there were the lawns and gardens exceeding in beauty their appearance last year, the paths (better surfaced) were filled with people, the lakes were alive with boats with their occupants of joy-gleaning folk; the air was filled with music. Some 121,000 visitors passed the turnstiles; and everyone seemed glad that the great exhibition was again open. If the evidence of popularity at the reawakening continues, there will have to be consideration as to whether Wembley has not become a permanent Imperial institution. But that is a matter for the future; sufficient for the present is the Wembley of to-day. Not only in the glorious sunlit grounds but in the buildings the people were found in large numbers investigating what was to be seen; and from what one witnessed of their interest and enthusiasm everywhere, it was clear that it was not only the pageantry of the morning and the ceremony of reopening by the King-Emperor, accompanied by the Queen, that had attracted them, but men and women of all conditions and places in our social system were giving practical effect to the words in the Royal speech: "To seek knowledge, more knowledge, and again more knowledge of the great heritage which has been entrusted to us is the soundest Imperial policy"—it is likewise the soundest individual policy. His Majesty hopes that the achievements of 1924 will be exceeded by those of 1925. We believe they will be; for when the stupendous work is presently done, those who have co-operated in it will "give a complete and vivid picture as before and yet a fresh picture," which "was a task calling for infinite resource and energy." The most belated work is the old quondam Palace of Engineering, now the Palace of Housing and Transport; and in the Palace of Industry there is still a good deal to be accomplished to give the final finish—particularly in the chemical section. But it is now simply a question of the unpacking of huge cases, and the arrangement of contents—everything is ready for their reception. Nevertheless there was more ready for inspection on the opening day than one could devote time to in a single visit. This year there will be more space available for the crowds in the buildings; and there will be more inducements for concentration upon the exhibits. Everything possible has been done to bring to bear upon this year's exhibition the experience gained in this remarkable Empire enterprise last year; and the exhibitors are going to benefit from what was learned in 1924.

It is altogether a lighter and brighter exhibition, and, in making it so, those responsible have given fresh opportunity to the gas industry. In his speech, His Majesty said that he noted with special pleasure that one of the great halls has been devoted to exhibits illustrating those problems of housing and transport which call so urgently for solution. It was a happy inspiration to make housing and house building a central feature of the exhibition, for the foundation of the Empire is the home. In the vast Palace of Housing and Transport on Saturday, the workers in brick and divers other structural materials, the painters, and the decorators were operating with might and main to bring to a finish what will be virtually a whole street of dwelling-houses, of different structural materials, of different design, and different equipment, and through the "B.C.G.A." and otherwise gas will be there, demonstrating the all-gas house, and the valuable contributor that it is to the liberty and leisure of the occupants. The adequacy of space will give more accommodation for inspection than one had of the temporary houses at another recent exhibition. Adjoining is the grand centenary display of the railway companies; and this is remarkably attractive to people. The fine modern locomotives, the saloon carriages, the demonstrations of signalling and control, all testify in themselves, and by comparison with locomotives of an early generation, to scientific and technical progress. In the same building there are the examples of the aeroplanes which are used by the "R.A.F.;" and there are motor-cars. Thus rail, road, and air transport are seen. It is an advantage for one exhibit to be in close touch with another which also draws people to Wembley and invites their interest, as will the railway centenary exhibits, the aeroplanes, motor-cars, and houses in this case. Having long since passed its centenary in public service, the gas industry can heartily congratulate the railway world upon the completion of its hundred years of service. As we pass out of the Palace of Housing and Transport, we notice standing derelict the building in which the domestic uses of electricity were demonstrated last year, and the electrical rendezvous now being devoted to an altogether different purpose.

In the Palace of Industry there is interest in abundance for the public; and centralized in its old buildings, redecorated, is the Gas Exhibit with extended accommodation and preparations nearing completion and perfection for a variety of demonstrations more far-reaching and spacious than the superficies admitted of last year. It would, we are satisfied, have been the height of folly for the industry not to have participated in the display this year. Great as were the opportunities last year, they will be greater this; and of them those in charge of our interests there are taking full advantage through the enlarged diversity of exhibits, an attractive presentment, and a programme in which is embodied the experience and knowledge gained during the six months' display in 1924. We have this year an Overseas Demonstration Hall, a General Exhibits Hall, a Lecture and Demonstration Hall, and Rest Lounge. The universality of gas use is to be seen by the examples of application from Canada, Australia, South Africa, India, and New Zealand; and a Pioneer's Store will serve to illustrate how the products

of coal carbonization contribute to the service of the industrial activities of our kith and kin across the wide seas. Science knows no bounds, nor does the gas industry; and technical and commercial interests are common wherever there is gas supply—the only exception being the ordinances which govern and control the operations of the industries in the various countries. Empire foodstuffs, and how they are cooked, will also engage attention. The idea of making the universality of gas one of the features of the Exhibit is in keeping with the Empire characteristics of the whole Exhibition. But this is only one of several features; and a wide range of domestic and industrial applications of gas will in a day or two be under demonstration. There will also be during the next six months strong emphasis laid upon the part the gas industry is taking in the national problem of smoke abatement; and the utilization of coke, tar, benzole, and its other products will be stressed. This is highly important in these days, when conditions have brought about a reduced demand. Enlarged requirements will come naturally from the revival of industry; but output is constantly on the increase not only from the gas industry, but from other sources. Educational work regarding the uses and merits of the secondary products must be on an intensified scale. Hence the greater attention that is being given to them in this year's display; hence, too, the road tar exhibit that the National Gas Council are making in the Chemical Section. All tar producers should support the Council in this matter, concerning which investigation and the compilation of the benefits realized as the result of practical experience are required. A serious campaign is necessary. The Exhibition this year gives the opportunity for a start in this. The importance of life in the Exhibit as an attraction has been fully realized, and is being materialized. There will be living tableaux, moving machinery, a daylight cinema, and lectures and cookery demonstrations. The spacious additional hall which has been secured, leading direct from the former halls, enables so much more to be done than last year.

As an educational centre for the gas industry, the Exhibit will be all that the 1924 display was, and much more; and every care is being taken to get not only the general public but people of influence in advisory and other capacities to come and see for themselves. The money provided by the gas-supply undertakings and by the manufacturers of plant and gas-using appliances is being well spent. Already excellent advertising has commenced, which will lead to the Palace of Industry, and to one of its central features—the Gas Exhibit. The descriptive article on later pages will supply readers with the details. Of this we are confident—when the finishing touches have been applied to the Exhibit, and the programme is in full swing, there will be general and cordial approval from the whole industry.

Apart from the Exhibit, a descriptive article is included in this issue which shows how extensively gas is being used in the processes of other exhibitors. We count this not an unimportant thing, as successful application by one manufacturer is an example, with the realization of efficiency and an overall economy, which other manufacturers in the same line of business will be induced to follow. Another special and illustrated article which will give gratification is that dealing with the catering arrangements for the multitude who will be visiting the Exhibition. Several well-known caterers are participating in the work this year; and with one accord they have adopted gas as their principal heating agent. We need not dwell upon this, because the act of adoption speaks louder than words, and the testimony is that of experts, to whom efficiency, economy, flexibility, and reliability are all-important.

Well satisfied as we were with the achievements of last year's gas display, we are hoping for more from this and from the attendant work. That result is being sought by those who are doing the main work in organization; and we heartily wish them a magnificent success. The assurance of this will be strengthened by every local effort throughout the industry to advertise the Exhibit, and to arrange for local influential men to visit it. The Exhibit belongs to the gas industry. Therefore, our counsel to gas undertakings is—Make good use of it.

Municipal Prohibition of Gas.

Many municipal authorities are the owners of electricity supply undertakings in competition with gas undertakings carried on, under statutory authority, by private enterprise. A gas undertaking administered by a company is a public service equally with a municipal electricity undertaking, and is usually a larger ratepayer than the latter. A municipal authority have no legal or moral right to interfere with the trading freedom of the gas company, and they have certainly no right to restrict the liberty of ratepayers to exercise their own will as to which concern they shall patronize for light, heat, and power. The Legislature has imposed upon gas undertakings the obligation to supply, under specified conditions, any occupier of premises with gas upon demand. That confers upon individuals a right which municipal authorities must be restrained from over-riding through their ownership of electricity undertakings. The possession of electricity trading powers by local authorities was never intended by Parliament to enable them to impose conditions upon any individual which would abrogate his rights under the General Law. The Newport (Mon.) Corporation thought the contrary. They have now been told, in effect, that they have no right to do anything of the kind—in other words, that they are not entitled to prescribe conditions which confer a preference upon their electricity undertaking, and which will interfere with the statutory authority and obligations of another trading concern in the area of their jurisdiction. The gas industry is the debtor of the Newport (Mon.) Gas Company for having set this matter right, and for having established a precedent in a measure promoted by the Corporation which can, for all time, be used should any other municipal authority seek to do what the Newport Corporation attempted.

What has occurred is an enlargement of something that had its inception in 1921, when the Corporation developed their housing scheme on the Somerton Estate. In the letting agreement which every tenant was obliged to sign, the Corporation inserted this condition: "The tenant hereby agrees as follows. . . . Not to use gas for the purpose of lighting the premises." There the tenants were deprived of exercising their own will of patronizing the form of light they preferred. In the present session of Parliament, the Corporation in their Bill sought power to develop any lands belonging to them, to erect houses, shops, offices, warehouses, and other like buildings, and to sell, lease, exchange, or otherwise dispose of such premises "upon and subject to such terms, conditions, and restrictions as they may think fit." Sub-section 2 of the clause gives power to the Corporation to grant leases of lands; and sub-section 3 provides that "the Corporation, in selling or disposing of such lands, may attach to the same, and may convey the same, subject to any conditions and restrictions upon the use thereof, and as to the buildings to be erected thereon, and as to the use to which such buildings may be put." We are not surprised that, in view of the condition imposed upon the tenants on the Somerton Estate as to not using gas for lighting, the Directors of the Gas Company and their Engineer and Manager (Mr. J. Herbert Canning) were apprehensive that the powers asked for in the Bill would constitute a statutory confirmation of the action of the Corporation, might be used to the prejudice of the Company and their present or prospective consumers, and might deprive the latter of their freedom of patronage, and abrogate the statutory obligations of the Company to the extent of a similar condition (as to the use of gas) imposed in respect of all lands and premises which the Corporation sold, leased, exchanged, or otherwise disposed of. It is significant that the Corporation refused to give the Gas Company any protection or assurance in relation to the clause; and therefore the latter had no option but to petition against the Bill. What, however, the Corporation declined to do, a Committee of the House of Commons did on Tuesday of last week. They saw the righteousness of the Gas Company's claim; and perhaps they also saw that the Corporation were endeavouring to take an undue advantage of their position to obtain preferential rights which could be used to the detriment of their trading competitor, by depriving of freedom of patronage of one of the

agents for light, heat, and power the occupiers of such premises and lands as were covered by the (in its unqualified form) objectionable clause.

The upshot was that the Committee accepted the protecting clause for which the Company had originally asked. It now stands as sub-section 4 of the Bill, and reads :

(4) The Corporation shall not make or impose under the powers of this section, any term, condition, or restriction with respect to the form of light, heat, power, or energy to be used in any house, shop, office, warehouse, or other building, or on any lands, or with respect to the taking from any particular local authority, company, body, or person of any form of light, heat, power, or energy.

That is a just clause. It protects not only the Newport Gas Company, but the purchasing liberty of the occupiers of all premises with which the Corporation have anything to do. Not only that—the clause is framed in a catholic spirit, and secures unfettered trading in the community for the suppliers of any form of light, heat, power, or energy. It is a valuable precedent. It would have been particularly harmful to the gas industry had the Corporation secured the powers originally sought by them without qualification, for that would have given a precedent of which other municipal authorities trading in competition with gas companies might have availed themselves. We congratulate the Newport Gas Company upon their action, the resistance to which by the Corporation shows that the former did not, in our opinion, misinterpret the intentions of the latter.

An Ugly Shock for 43, Cannon Street.

An ugly shock has been administered to the company promoters who have made their nest at 43, Cannon Street; and we hope, now that a Government Department has got into close touch with Colonel Eaton and his associates or puppets, something will be done to make such effective public exposure that their activities will be much curtailed or, better still, altogether suppressed. People who consider that they are clever at the form of company promotion that has been carried on with such fervour from the address mentioned, sometimes make a false move which is a considerable disadvantage to them, and an advantage in revelation to other people, including their victims. What has happened is that the Barford Electric Supply Company, the shares in which were bought by the Eaton group and the associated concern the "Warwickshire and South Midland Electricity Supply Corporation, Ltd.," applied to the Electricity Commissioners for an Order, with the view possibly, if obtained, of utilizing it as a lever for extracting further money for this "enterprise" from the pockets of the easily misled section of the public on whom this type of promoter lives. The Leamington and Warwick Electric Company also applied for an Order; and this led to an inquiry being arranged by the Ministry of Transport, which was conducted by Colonel C. T. Ekin, assisted by Mr. W. Cooke. When the inquiry was held at Leamington, the Inspector soon found that there was no more intention on the part of these Cannon Street gentry of letting him peep further behind their financial scenes than they are accustomed to do in divulging to the public, when inviting subscriptions for capital, the exact financial position of, and actual business done by, the puny concerns which are their nuclei, and to which mostly big territorial names are given, and, to obtain proper symmetry and for other reasons, capital to match is sought. The Leamington and Warwick Electric Company ought to be thanked, by all who desire honest company promotion, for the part they, through their Counsel, Mr. Craig Henderson, K.C., took in bringing about the revelations in this case—revelations drawn from the reluctant mouth of Mr. C. A. Turner, who acts as auditor and accountant for several of the Eaton promotions, and whose admissions suggest that he works dutifully to instructions.

The inquiry occupied two days; and it was on the first day that Mr. Turner made what are described by one report as his "startling admissions," and felt somewhat the worse for wear after he had undergone a searching cross-examination by Mr. Craig Henderson, and pertinent questioning by the Inspector, who was evidently not altogether in the dark as to the character of promotion with which he had to deal. Among other points, the much prospectus-advertised Turner had to confess that Eaton had been attacked very severely in practically all the financial papers (others could be mentioned) with regard to undertakings which he had launched on the public; and attention was called to an uncomplimentary epithet that had been applied by "Truth" to Eaton, while witness had been described as his "tame auditor." Mr. Turner admitted that no notice had been taken of these hurtful epithets. Probably the high sense of delicacy that resides at 43, Cannon Street has prevented any action being taken, or maybe these men consider that their position in public estimation enables them to treat their critics with contempt. But the fact remains that the criticism that has been directed against their schemes from all sides has not tempted them to enter the Courts to prove the purity and soundness of their schemes and their philanthropic motives in offering the public "investments" carrying the promise on paper of high interest or remarkable dividends. On the second day of the inquiry, Colonel Eaton and Mr. Turner—probably discreetly—did not put in an appearance. We are not surprised. For Eaton to have to sit and hear during one day things such as were said about his guileless promotions must have lacerated his very soul; and Mr. Turner, we should imagine, had no particular wish to be at hand on the second day for further interrogation, should the Inspector or Mr. Craig Henderson have discovered during the adjournment fresh information they desired to elicit—especially in view of the fact that the Inspector had announced his intention of visiting the hydro-electric generating station before resuming the inquiry on the second day. Mr. Turner called it the "factory;" and Counsel stated that it was otherwise known in the district as "the old mill!"

It appears from the evidence that, before the Cannon Street group got the Barford concern into their hands, the capital consisted of 1200 ordinary shares of £1 each and 2200 preference shares of 10s. each. But Mr. Turner says the fully subscribed capital of the Company is now £23,024! Mr. Craig Henderson put this question: "So this little concern at Barford, valued at £3000, is made responsible for £10,000 loan capital, £15,000 share capital, the associated working Company has got 12,000 preference shares, nearly 12,000 debentures, and altogether £23,000 odd of subscribed capital?" Mr. Turner replied "Yes." The money was sought and obtained before the Order was applied for! A later question by Counsel divulged the fact that 62 women and 52 men were on the shareholders' list—the women having subscribed £6813, and the men £3344. "Don't you think that is pathetic?" asked Mr. Craig Henderson. And the estimable Mr. Turner replied: "I don't see that at all." That these people distribute their precious documents in no half-hearted way is seen from the fact admitted by witness that £383 had been spent on postages in circulating this Company's prospectus. That sum is equal to 91,920 pennies; thus Counsel was justified in putting the copies distributed at 90,000. Another interesting point is that in the preparation of the wonderful reports bearing the name of Mr. Turner, which appear in the prospectuses sent from 43, Cannon Street, or the provincial offices from which operations are sometimes conducted, that gentleman works to "instructions." Figures are placed before him; and from them he prepares percentages. Any schoolboy could do that. He had no books or figures available at the inquiry which were required either by the Inspector or Mr. Craig Henderson; and he acknowledged that the big percentage increases in revenue and business were simply prepared by him on the figures that the promoters gave him. And when people see these high percentages and the promise of big returns on their money, they must expect a risk—according to Mr. Turner. Of course, this depends upon who the people are. The prospectuses of these promoters, in the work of whom Mr. Turner professionally participates, reach all sorts and conditions of intelligences.

All through it was a sorry spectacle; but excellent service has been done to the public in getting so far

behind the scenes as to see how these things are worked. Another question put to the same witness was: "Has Eaton not 'rung the changes' from one company to another?" The reply was: "That is no business of mine, is it?" This gave Counsel the opportunity to say: "If you put 'is it' to me, I tell you I should make it my business to see it did not continue." To which Mr. Turner replied: "I did not say I should not take action in the matter; but I have not done so up to the present." Why not? Small wonder that the Inspector said he was very dissatisfied with the evidence of the witness—particularly in view of the fact that a letter was sent to the Company on April 6, stating that it would be necessary for the respective promoters to furnish the fullest technical and financial information; and yet regarding 50 p.ct. of the questions put to witness, he knew nothing. The local evidence was firmly against powers being granted to the Barford Company and its associate the "Warwickshire and South Midland Electricity Supply Corporation, Ltd.," for both of whom (if they are really divisible) Mr. Wilfrid Burton appeared. He seemed somewhat surprised at the course the proceedings had taken; and, before the inquiry closed, he took the opportunity of saying to the Inspector: "The evidence I have put before you is not of the nature I am used to dealing with." To this Colonel Ekin replied: "I hope for your sake it is not." It is a singular coincidence that one of the Directors of the Warwickshire and South Midland Electricity Supply Corporation, Ltd., and the Wareham Electric Supply Company is Wilfred (not Wilfrid) Burton; and Wilfred Burton—a Solicitor's Managing Clerk—subscribed for 100 founders' shares in the Electric Light and Power Contracts Finance Corporation, Ltd.—the three Companies progeny of the 43, Cannon Street clique. What we sincerely hope is that the disclosures on this occasion will have an effect on the operations of this promoting group which will be beneficial to the public. The best effect would be the final business extinction of these people, who obtain money from unsuspecting folk by the mean artifice of extravagance, and that vividly coloured.

Income-Tax Allowances for Wear and Tear.

It may be inferred from the useful little paper, read by Mr. W. M. Galleway, of Whitby, before the members of the North of England Gas Managers' Association last Friday week, that gas companies are still in existence who are not economizing, in one respect, in their outgoings to the extent that they might do. The contribution deals with a subject which has perennial interest for the secretaries and managers of gas undertakings—that is, income-tax allowances for wear and tear of gas-works plant, including meters (ordinary and prepayment), gas stoves, fires, &c. In effect, the paper shows the advantages there are to small or medium-sized gas companies in adopting the scheme for determining income-tax allowances for wear and tear and maintenance which resulted from the discussions and the work of a Committee representing statutory gas companies in negotiating, in 1912, with the Inland Revenue Authorities. The whole question at that time was a highly controversial one, and caused no end of vexation and worry to those who had year after year to treat of these matters. It was therefore a happy termination to the work undertaken, with masterly skill and diplomacy, by the Committee referred to, when a definite agreement was reached. Nearly everybody concerned was heartily glad, though a few critics still remained who thought that gas companies had not got all they should have. Perhaps they did not; but the fact was that they had obtained a settlement with the authorities which has proved invaluable. Of course, acceptance of the agreement was not compulsory. It could be adopted at will by gas companies all over the country; and to those who did not subscribe to it, appeal was open precisely as before. In view, however, of the fact that statutory gas companies representing a large proportion of the capital of private gas enterprise endorsed it, made it practically universal in its application. In the paper by Mr. Galleway the agreement is set out in the form in which it was published in 1912.

Three years later the scheme was adopted by the Whitby Gas Company; and although there was a little hesitation on the part of the surveyor of taxes in accepting the claim of the Company as originally presented to him, an inspection by him of the Company's books resulted in his admission of the correctness of the claim. The scheme was put into operation and worked until 1921, without any exception being taken by the Revenue Authorities, notwithstanding the fact that the allowance for wear and tear exceeded the amount of tax deducted for the interest and dividends paid annually to stock and share holders. About that time, however, a new inspector of taxes was appointed; and he refused to allow depreciation at the rates to which the Company were entitled, and which they had been allowed from the period of the adoption of the scheme. What the new inspector contended was that the Directors were compelled by the Customs and Inland Revenue Act, 1888, section 24, sub-section (3), to pay over to the Commissioners of Inland Revenue the full amount of the tax deducted from dividends and interest paid to the debenture stockholders and shareholders from year to year, irrespective of any claim which the Directors had for depreciation. His intention therefore was only to allow a sum equal to the amount written off annually for depreciation as shown in the statements of accounts. The result of this objection on the part of the new inspector is interesting, in view of the further confirmation it gave to the agreement. Naturally the Directors maintained they were entitled to the full allowance of 3 p.ct. on gasholders and 10 p.ct. on meters, gas stoves, &c., as provided for in the scheme, and that there was no reasonable ground for raising an objection to what had become an established precedent. Expert advice and Counsel's opinion were obtained, and both confirmed the Directors' contention. The upshot was that the inspector's objection was withdrawn. The scheme is therefore still in operation, and to the advantage of the undertaking, though it is an advantage which is only just.

Those gas companies who have not adopted the scheme should consider Statement B in the paper. This gives some idea of the benefits which have, since the scheme was put into operation, accrued to the Whitby Company and their customers. Looking at the figures, one can appreciate Mr. Galleway's opinion that those undertakings which are not under the scheme would do well to give serious consideration to whether it is not to their interest to claim the allowances which are granted by it. As a matter of fact, we cannot understand any statutory undertaking entitled to come under the agreement rejecting the certain allowances obtainable under it, unless they are enjoying fair treatment otherwise, and so are loath to disturb the existing arrangements.

A Big Coke Contract.

It has been known for a long time that at the Greenwich power station which supplies energy to the London tramways, gas coke is used with coal for boiler firing; and in the past, some good figures have been made public as to a considerable resulting economy. Among the contracts settled last week by the London County Council was one with the South Metropolitan Gas Company for 45,000 tons of coke for the Greenwich station. Knowledge of the large use to be made of coke at this important station may serve the good end of stimulating a greater interest among electrical engineers in the advantages for steam-raising of utilizing coke in company with the cheaper varieties of small coal and slack on (say) the "Sandwich" system. The coke position to-day urges that no effort should be spared to cultivate all the demand possible in every direction.

Special Orders and the One-Half Proportion.

Perhaps we did not in the note published last week make it altogether clear that one object of the Aldershot Gas, Water, and District Lighting Company in the Special Order for which they are applying to the Board of Trade is to continue, in their case, the temporary provision of the Public Utility Companies (Capital Issues) Act as to the one-half proportion of borrowing powers to paid-up capital. The Act will expire on the 20th inst. Mr. A. S. Campbell, of Wellingborough, points out the position in our "Correspondence" columns. He says: "The novelty of the Aldershot application lies in the fact that it is the first application for such temporary powers under the Act

to be made permanent "—that is, the extension of the borrowing powers to one-half the amount of the issued and paid-up share capital. As a matter of fact, it cannot be described as a novelty or a precedent. The one-half borrowing proportion is now a common clause in Special Orders, as it had been previously for many years in Gas Acts. Moreover, the Aldershot Company cannot, we find, claim novelty for continuing by Special Order the provision of the Public Utility Companies (Capital Issues) Act. In 1921, the Romford Gas and Coke Company, Ltd., obtained a "Capital Issues" Consent from the Board of Trade; and the Secretary of the Company (Mr. G. Berridge) calls our attention to the clause which they secured in their Special Order of 1922, and which perpetuated the one-half proportion of borrowing powers. The clause reads: "11.—(1) Section 14 (Limit of Borrowing Powers) of the Order of 1904 is hereby repealed. (2) The amount of all moneys borrowed by the Company, and secured by mortgage of the undertaking, shall not at any time exceed in the whole one-half of the amount of the capital of the Company for the purposes of the undertaking actually raised by the issue of shares or stock, including any premium obtained on the sale of such shares or stock."

Small Unit Nitrogen Fixation Plants.

Dr. Luigi Casale, the inventor of the Italian process for the fixation of atmospheric nitrogen, has been entertained to dinner in London by a number of scientists. On the occasion, the Technical Director of the United Alkali Company (Dr. G. C. Clayton, M.P.) made an important statement as to developments of nitrogen fixation in this country. He said that after the great war it was felt that the country must have an independent source of synthetic ammonia. A Haber plant is working satisfactorily at Billingham; but Dr. Clayton points out that this is only one plant, and might be a source of great danger in the case of air raids. In addition, the Haber plant, in order to realize the maximum success, must be installed on a large scale. This, according to Dr. Clayton, is where the Casale plant comes in. It can be made in smaller units and distributed throughout the country, and this segregation would greatly minimize risks from air raids. In this matter, Dr. Clayton is evidently a strong believer in "security first."

PERSONAL.

Mr. A. Cook, Assistant Engineer and Manager to the Warrington Corporation Gas Department, has been appointed Engineer and Manager to succeed Mr. W. S. Haddock, who retires on June 30.

Spontaneous Combustion of Coal.

Discussing, in "Industrial and Engineering Chemistry," the question of the deterioration and spontaneous combustion of coal in storage, Mr. S. W. Parr, of the University of Illinois, says it is difficult to summarize the information which he presents in terms of possible rating as to storage adaptability of specific coals. The fundamental factors involved, however, would seem to suggest the propriety of assigning storage qualities on the basis of size rather than type. For example, the high-moisture coals of the lignitic type would be set down as the most difficult, or impossible, to store without heating. The next in order of betterment would be the bituminous coals having from 12 to 15 p.ct. of moisture. The paramount factor in all bituminous coals, however, is fineness of division. This would include, of course, tendency to breakage, and the production of fines in the process of shipping and handling. Those coals which disintegrate least on weathering are less ready to start active chemical reactions in the pile. Lump sizes free from duff may be safely stored. In coals of the low-volatile type there is a low-water content and a greatly reduced avidity for oxygen; but these qualities, which should contribute directly to the storing properties of these coals, are frequently offset by structural peculiarities that contribute to the ease with which they disintegrate and develop fine material. However, it should be noted that, because of the greatly reduced absorption capacity of such coal for oxygen, the fines do not have nearly the danger that attaches to fine material from the high-moisture coals. Although initial reactions resulting in the development of heat may have their origin in the carbonaceous substance, independent of the presence or absence of sulphur, still it must appear that this latter element constitutes an added feature requiring consideration. But since the danger from sulphur largely centres in the duff, an added argument appears for eliminating the fine material from the mass.

ELECTRICITY SUPPLY MEMORANDA.

Colliery Super-Stations and Consumers' Charges.

The idea of big super-stations in colliery districts has lost much favour in electrical circles. The recession from the worship of such stations has been a gradual one. First, the experts began to wonder where the water for condensing purposes was to be obtained in proximity to coal mines. Then it dawned upon them that huge transmission systems running through miles and miles of rural territory, with little demand there, would be costly, upkeep great, and losses of electrical energy painful to contemplate. When they came to balance up things, the conclusion was reached that what might be saved on generating fuel at the pit-head would be more than swallowed up by the transmission costs and losses. Now labour developments are considered to be a factor; and there are doubts as to the wisdom of placing stations where the miners can, to serve their own ends, bring influence to bear upon them. The combination of miners and the Electrical Trades Union would indeed constitute a potent alliance with the means of generation located at the collieries. It is easy enough to vision some most unhappy consequences of such concentration of generation—if practically feasible—with concentration of labour power. In times of war, too, the collieries and the generating stations at them would form fine objectives for an enterprising enemy. Large dimensioned generating stations so situated, we are inclined to think, would be stoutly resisted by the electricity industry. The whole object of such location is cheapening of electricity supply. One way of bringing this about, without all the bother of reconstruction, would be by making it illegal for municipal authorities to extract profit from their electrical undertakings (and the same should apply to their other productive concerns), and to bring electricity companies under the sliding-scale system of price and dividends. Speaking of charges, no one in the electricity industry seems disposed to come forward with a scheme for selling electrical energy on the therm basis, so that the two competing industries would be on an equality—so far as the basis goes. We are afraid electrical men do not take the idea seriously. If they did, no one would be more surprised than we should be. If any electrical man would argue the matter in favour of adoption, he could drag in the support of the vaunted efficiencies of electrical operation. See how they would help him!

Tariffs and Development.

In the "Memoranda" for April 22, notice was made of two papers, which had recently been read at a meeting of the Institution of Electrical Engineers, on the subject of scientific two-part tariffs. It will be remembered that one of these was jointly by Mr. George Wilkinson and Mr. R. M'Court. In the discussion, there was a considerable amount of criticism of the methods proposed by the authors, chiefly on account of the additional complexity which it was thought would be introduced, and which would be altogether beyond the understanding of consumers. Mr. Wilkinson has contributed an article to the "Electrical Times," with the intention of disposing of the criticism. In his opinion, the opposition is largely due to the fact that the uniform tariff advocated has been examined and criticized on the basis of present-day development and experience rather than on the conditions which will obtain when electricity is commonly used for all labour-saving purposes, both in the house and in the shop. For the sake of the gas industry, we hope (and there is some basis for it) that the conditions which Mr. Wilkinson has in view will not develop. In the existing two-rate tariffs, he finds defects and glaring inconsistencies. Most of us have done that—in fact, their presence has been observed from the very introduction of the systems. Mr. Wilkinson is enthusiastic He believes that a closer investigation of the subject will probably establish the view that the enormous additional business waiting to be picked up at the very doors of every supply undertaking, which dazzles the eye and excites the mind of the imaginative, will never be attained while the existing tariffs remain. Present-day tariffs have, after many years of hard work and able management, approximated to an average load factor of about 25 p.ct.; but our friend who is trying to devise means for putting our industry to death asks what about the next 25 p.ct., and the possible next. Then he takes the case of an undertaking disposing of a modest top load of 3000 kw.

> With good management and economical operation we assume it has attained to a load factor of 25 p.ct.; and, therefore, in round figures, is disposing of 6,500,000 Board of Trade units a year. The cost of this service will, with modern plant, be round about 0·4d. for fuel, oil, and stores per unit sold, *plus* all the fixed charges. But what will be the cost of the next 6,500,000 units representing an increase in the load factor from 25 to 50 p.ct.? There are no additional fixed charges, there are no additional losses in the boiler-house, transformer excitation, meter shunts, &c. Therefore, as the additional load is to be obtained by spreading the supply over double the number of hours per day, the coal figure of 0·4d. per unit sold will be reduced in respect of the extra units by 25 p.ct.—viz., to 0·3d. Add 10 p.ct. for profit;

and we have 6,500,000 more units available for the use of consumers at the attractive figure of ¾d. per unit, or 13,000,000 units at the same low price if the load factor can be raised to 75 p.ct.

It is held by Mr. Wilkinson that present-day tariffs and methods of selling and use will not bring "this wonderful and perfectly possible boon upon the country; but it is attainable." The first essential towards demand is, he says, a two-part tariff with its fixed charge based on the electrical requirements of the consumer, with a very low price, (say) 0·33d. per unit, for all additional units taken. This tariff, in his opinion, will at once enable the consumer to relieve, on sound financial lines, his household and shop of much drudgery. Mr. Wilkinson is looking far ahead. Every electrical engineer has to consider his present practical conditions, and operate with them for his guide. He cannot assume the conditions of the future, nor can he apply to his present-day circumstances the unformed happenings of a distant period. Development to the point to which Mr. Wilkinson is aiming must come (if ever) by the process of evolution. We quite agree with him that, if a two-part tariff is adopted, the fixed charge should be based on the electrical requirements of each consumer. That is the only rational basis.

How is it to be Attained?

Mr. Wilkinson asks how what he suggests is to be attained? How can the extra energy be disposed of among existing consumers and usefully employed by them? We quote *in extenso* the answer he gives:

1. By a uniform tariff (two-rate) as set forth, based upon the electrical requirements of the household.
2. By wiring the consumer's premises on two circuits, the first being the "indispensable" circuit upon which electric service must always be available, and the second, which may be termed the "dispensable" circuit, supplying the water heating, part of the cooking apparatus, and such labour-saving devices as can conveniently be used during the periods of lighter loads.
